The flowers of this species of violet, besides their beautiful colour, have a peculiar agreeable odour, and a very slightly bitter taste. These properties they yield to boiling water; and their infusion affords a very delicate test for acids and alkalies, being reddened by the former, and rendered green by the latter. Their odour is destroyed by desiccation; and the degree to which they retain their fine colour depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room, or by exposing them to a current of very dry air.

The flowers of other species are often mingled with them, and, if of the same colour, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of *Viola odorata*, M. Boullay discovered a peculiar alkaline principle, bearing some resemblance to *emetia*, but possessing distinct properties. He called it *violine* (*violia*). It is white, soluble in alcohol, scarcely soluble in water, and forms salts with the acids. It exists in the plant combined with malic acid, and may be obtained by treating with distilled water the alcoholic extract of the dried root, decomposing by means of magnesia the malate of violia contained in the solution, and extracting the alkali from the precipitated matters by alcohol, which yields it on evaporation. To obtain it entirely pure, a more complicated process is necessary. Orfila has ascertained that it is exceedingly active and even poisonous. It is probably contained in most of the other species of Viola.

Medical Properties, &c. of the Violets. The herbaceous parts of different species of violet are mucilaginous, emollient, and slightly laxative; and have been used in pectoral, nephritic, and cutaneous affections. Much was formerly thought of the *Viola tricolor*, or *pansy*, as a remedy in crusta lactea. A decoction in milk of a handful of the fresh herb was taken morning and evening, and a poultice made with the same decoction was applied to the affected part. Cures in numerous instances are said to have been effected by this treatment, persevered in for some time. Our own *Viola pedata* is considered a useful expectorant and demulcent in pectoral complaints. (*Bigelow.*)

In Europe, a syrup prepared from the fresh flowers of *Viola odorata* is employed as an addition to demulcent drinks, and as a laxative for infants. The seeds were formerly considered beneficial in gravel, but are not now used. The root, which has a bitter, nauseous, slightly acrid taste, acts in the dose of from thirty grains to a drachm as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets; as it is known to be by several species of Ionidium, which belongs to the same natural family. The existence in small proportion of the emetic principle, upon which the powers of the root probably depend, in the leaves and flowers, accounts for the expectorant properties attributed to these parts of the plant.* W.

* *Syrup of Violet.* This was officinal with the Lond. and Ed. Colleges; and, though it has been discarded in the British Pharmacopœia, yet, as it may sometimes prove useful, we give the London formula for its preparation, with the remarks upon it contained in the eleventh edition of the Dispensatory.

"Take of Violets [recent petals] *nine ounces;* boiling Distilled Water *a pint* [Imperial measure]; Sugar [refined] *a sufficient quantity;* Rectified Spirit *a sufficient quantity.* Macerate the Violets in the Water for twelve hours; then express, and filter. Set apart that the dregs may subside; then add a weight of the Sugar double that of the liquid, and dissolve with a gentle heat. Finally, when the syrup has cooled, mix with each fluidounce of it half a fluidrachm of the Spirit." *Lond.*

This syrup has a deep-blue colour and an agreeable flavour. It is said that its colour is most beautiful when it is prepared in well-cleaned pewter vessels; and the influence of the metal is ascribed by M. Augillis, of Ypres, to the attraction of the tin for nascent acetic acid, which he thinks is produced in the flower by fermentation, and has the effect, if not neutralized, of impairing its colour. (*Journ. de Pharm.*, Sept. 1856, p. 194.) As it is apt to fade by time, it is sometimes counterfeited with materials the colour of which is more permanent. The fraud may usually be detected by the addition of an acid or alkali, the former of which reddens the syrup of violets, the latter renders it green, while they produce no such change upon the counterfeit. It should not have the smell or taste of red cabbage, a syrup of which acts in the same way with acids and alkalies.

This syrup acts as a gentle laxative when given to infants in the dose of one or two fluidrachms; but it is used chiefly as a test of acids and alkalies. For the latter purpose a syrup prepared from the juice of the red cabbage may be substituted. It is very seldom kept in our shops.

XANTHORRHIZA. *U. S. Secondary.*

Yellow-root.

The root of Xanthorrhiza apiifolia. *U. S.*

Xanthorrhiza. *Sex. Syst.* Pentandria Polygynia. — *Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx none. *Petals* five. *Nectaries* five, pedicelled. *Capsules* five to eight, one-seeded, semibivalve. *Nuttall.*

Xanthorrhiza apiifolia. Willd. *Sp. Plant.* i. 1568; Barton, *Med. Bot.* ii. 203. — *X. tinctoria.* Woodhouse, *N. Y. Med. Repos.* vol. v. This is an indigenous shrub, two or three feet in height, with a horizontal root, which sends off numerous suckers. The stem is simple, rather thicker than a goose-quill, with a smooth bark, and bright-yellow wood. The leaves, which stand thickly at the upper part of the stem, are compound, consisting of several ovate-lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. The nectaries are obovate and bilobed, the styles usually about six or eight in number.

The yellow-root grows in the interior of the Southern, and in the Western States. Nuttall says that it is abundant on the banks of the Ohio. It flowers in April. The root is the part directed by the Pharmacopœia ; but the bark of the stem possesses the same virtues.

The root is from three inches to a foot or more in length, and about half an inch in thickness near the stem. It shrinks somewhat in drying, and, as found in the shops, is in slender pieces of various lengths, diminishing from three or four lines in thickness to the dimensions of a knitting-needle, wrinkled longitudinally, with a light yellowish-brown, easily separable epidermis, a thick, hard, bright-yellow woody portion, and a very slender central pith. It is inodorous, and of a simple but extremely bitter taste. It imparts its colour and taste to water. The infusion is not affected by a solution of sulphate of iron. By the late Professor Barton the bark of the root was considered more bitter than its ligneous portion. Dr. J. Dyson Perrins extracted from it an alkaloid which, both in its reactions and composition, so closely resembled *berberina* that there can scarcely be a doubt of their identity. (*Pharm. Journ.*, May, 1862.)

Medical Properties and Uses. Xanthorrhiza possesses properties closely analogous to those of columbo, quassia, and the other simple tonic bitters; and may be used for the same purposes, and in the same manner. Dr. Woodhouse employed it in the dose of two scruples, and found it to lie easily upon the stomach. W.

XANTHOXYLUM. *U. S. Secondary.*

Prickly Ash.

The bark of Xanthoxylum fraxineum. *U. S.*

Xanthoxylum. *Sex. Syst.* Dicœcia Pentandria. — *Nat. Ord.* Terebintaceæ, *Juss.*; Xanthoxylaceæ, *Lindley.*

Gen. Ch. Male. *Calyx* five-parted. *Corolla* none. Female. *Calyx* five-parted. *Corolla* none. *Pistils* five. *Capsules* five, one-seeded. *Willd.**

* The fruit of *Xanthoxylum alatum*, growing in Northern India and China, is known by the name of *Japanese pepper*, being used as a condiment in Japan and China. It is in small roundish capsules, of which one or more stand upon a peduncle, of a reddish-brown colour, and beset externally with numerous little prominences, which appear to enclose the oil to which the fruit owes its pungency. The flavour of the capsule is aromatic, pungent, and agreeable. The seeds are black, shining, and destitute of pungency. Dr. Stenhouse has obtained from the fruit by distillation a liquid volatile oil, isomeric with oil of turpentine, which he calls *xanthoxylene*, colourless, and of an extremely agreeable odour; and a crystalline stearoptene, which separates from the liquid on cooling. This he calls *xanthoxylin.* It is slightly aromatic, insoluble in water, soluble in alcohol and ether, fusible and volatilizable unchanged. (*Pharm. Journ.*, xvii. 19, and N. S. ii. 554.)—*Note to the eleventh and twelfth editions.*

Xanthoxylum fraxineum. Willd. *Sp. Plant.* iv. 757; Bigelow, *Am. Med. Bot.* iii. 156. — *X. Americanum*, Miller; Torrey and Gray, *Fl. of N. Am.* i. 214. The prickly ash is a shrub from five to ten feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface. The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polygamous; some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. Each fruitful flower is followed by as many capsules as it had germs. These capsules are stipitate, oval, punctate, of a greenish-red colour, with two valves, and one oval blackish seed. This species of Xanthoxylum is indigenous, growing in woods and in moist shady places throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odour recalling that of the oil of lemons. The bark is the officinal portion.

Properties. This, as found in the shops, is in quills, from one or two lines to nearly an inch in diameter, thin, externally of a darkish-gray colour diversified by whitish patches, with the epidermis in many pieces marked by closely set transverse cracks, internally finely striated longitudinally and somewhat shining, and, when derived from the smaller branches, exhibiting occasionally remains of the prickles. The bark is very light, brittle, nearly or quite inodorous, and of a taste which is at first sweetish and slightly aromatic, then bitterish, and ultimately acrid. The acrimony is imparted to boiling water and alcohol, which extract the virtues of the bark. Its constituents, according to Dr. Staples, besides fibrous substance, are volatile oil, a greenish fixed oil, resin, gum, colouring matter, and a peculiar crystallizable principle which he calls *xanthoxylin*, but of which the properties are not designated. (*Journ. of the Phil. Col. of Pharm.*, i. 165.) It is probably identical with the bitter crystalline principle found by MM. Chevallier and Pelletan in the bark of Xanthoxylum Clava Herculis, and named by them *xanthopicrite;* and this has been found by Mr. Perrins to be identical with berberina; so that the prickly ash is to be added to the list of medical substances, already large, in which this widely diffused alkaloid is contained. (*Pharm. Journ.*, March, 1863, p. 403.)

A specimen of bark has been shown to us, collected on the shores of the Chesapeake Bay, and said to be the product of *Xanthoxylum Clava Herculis*, though probably derived from the trunk of the *X. Carolinianum*, as the X. Clava Herculis is a native of the West Indies, and not of the United States, and the X. Carolinianum grows in Virginia. Prof. Bentley first indicated this probable origin of the bark, which, in the eleventh edition of the Dispensatory, was conjecturally referred to the trunk of the officinal species. The specimen referred to resembles the bark above described considerably in its general characters, but differs in consisting of irregular fragments of a bark of larger dimensions, flat or but slightly rolled, and exhibiting, on the outer surface of some of the fragments, large conical, corky eminences, which serve as the bases of the spines, and no doubt give to the trunk of the tree the rough, knotty appearance, which obtained for its congener the name of the club of Hercules

The researches of Prof. Robert Bridges, made since the publication of the twelfth edition of the Dispensatory, leave no room to doubt that the bark known in the South as the prickly ash bark is that of the X. Carolinianum. (*Am. Journ. of Pharm.*, March, 1865, p. 134.)

Dr. Bigelow states that the *Aralia spinosa*, or angelica tree, which grows in the Southern States, is occasionally confounded with *X. fraxineum*, in consequence partly of being sometimes called, like the latter, *prickly ash.* Its bark, however, in appearance and flavour, is entirely different from xanthoxylum.

Medical Properties and Uses. Xanthoxylum is stimulant, producing, when swallowed, a sense of heat in the stomach, with more or less general arterial excitement, and a tendency to diaphoresis. It is thought to resemble mezereon and guaiac in its remedial action, and is given in the same complaints. As a remedy in chronic rheumatism, it enjoys considerable reputation in this country. The dose of the powder is from ten grains to half a drachm, to be repeated three or four times a day. A decoction, prepared by boiling an ounce in three pints of water down to a quart, may be given in the quantity of a pint, in divided doses, during the twenty-four hours. The powder has sometimes been employed as a topical irritant; and the bark, used as a masticatory, is a popular remedy for toothache, and has been recommended in palsy of the tongue. W.

ZINCUM. *U. S., Br.*

Zinc.

Zinc of commerce. *Br.*

Speltre; Zinc, *Fr.;* Zink, *Germ.;* Zinco, *Ital., Span.*

Zinc occurs native in two principal states; as a sulphuret, called *blende*, and as a carbonate and silicate, to which the name of *calamine* is applied indiscriminately.* It has been detected, in the vegetable kingdom, in a peculiar violet growing on the calamine hills of Rhenish Prussia. It is found most abundantly in Germany, whence the United States have, until recently, been chiefly supplied.† The metal is extracted generally from calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders, placed horizontally over a furnace. When the reduction of the zinc commences, iron receivers are adapted to the opening of the cylinder to condense the volatilized metal. The metal is then melted and run into moulds, and forms *speltre*, or the zinc of commerce. In this state it contains iron, and traces of lead, cadmium, arsenic, copper, sulphur, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom, and open at both ends; its upper extremity reaching a little more than half way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and, passing down the tube by a descending distillation, condenses in the water below.

Properties. Zinc has a bluish-white colour, a peculiar taste, and a perceptible smell when rubbed. Its texture is laminated, and its fracture crystalline. Its malleability and ductility are not very great. When perfectly pure, it may be reduced to thin leaves at ordinary temperatures; but the zinc of commerce requires to be heated to a temperature between 212° and 300° to render it sufficiently malleable to be rolled into sheets. The softness of zinc is peculiar, as is shown by the circumstance that it clogs the file, when the attempt is made to reduce it to filings; and hence to have it in the divided form, it is necessary to melt it, and triturate it at the moment of solidification. Its sp. gr. is about 6·8, its equivalent 32·3, and symbol Zn. Favre makes its equivalent 32·99, and Erdmann, 32·527. Subjected to heat it fuses at 773°. At full redness it boils, and in close vessels may be distilled over; but in open vessels it takes fire, and burns with a dazzling white flame, giving off dense white fumes. It dissolves in most of the acids with disengagement of hydrogen, and precipitates all the metals either in the metallic state, or in that of oxide. It forms but one well-characterized oxide (a protoxide), and but one sulphuret. The protoxide is officinal, and will be described under another head. (See *Zinci Oxidum.*)

* A small piece of native zinc was exhibited at the International Exhibition at London, in 1862, among the products of Australia, being the first specimen that had been seen of the metal in this state. (*Chem. News*, July 26, 1862.)

† Zinc is now largely manufactured near Bethlehem, Pennsylvania, at the zinc works of the Lehigh Zinc Company. The ore worked is the silicate or electric calamine. Sulphuret of zinc (blende) and sulphuret of cadmium are also found in the same locality. From picked specimens of the ore nearly pure zinc has been obtained. (*Am. Journ. of Pharm.*, Sept. 1860, p. 407.)—*Note to the twelfth edition.*

Zinc of good quality dissolves in dilute sulphuric acid, with the exception of a scanty grayish-black residue. If absolutely pure, it would be wholly dissolved. The solution is colourless, and yields white precipitates with ferrocyanide of potassium and hydrosulphate of ammonia. Ammonia throws down from this solution a white precipitate, which is wholly dissolved when the alkali is added in excess. If copper be present, the solution will be rendered blue by the ammonia; if iron, it will be thrown down by this alkali, but not redissolved by its excess. Arsenic may be detected, unless present in very minute proportion, by dissolving the zinc in pure dilute sulphuric acid in a self-regulating reservoir for hydrogen, when arseniuretted hydrogen will be formed, recognizable by its flame producing a dark stain on a white plate.

Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction with copper, for galvanic combinations. Combined with tin and mercury, it forms the amalgam for electrical machines. Its solution in dilute sulphuric acid furnishes the readiest method for obtaining hydrogen. With copper it forms *brass*, and, in the form of *sheet zinc*, it is employed to cover the roofs of houses, and for other purposes. It is also applied to the covering of iron, to protect it from oxidizement, in the same manner as tin, forming what is known commercially as *galvanized iron*. It should, however, never be used for culinary vessels, as it is soluble in the weakest acids. Zinc and its oxide are dissolved to a certain extent by water containing common salt; a double chloride of zinc and sodium being produced in solution. (*Journ. de Pharm.*, Nov. 1867, p. 397.)

The compounds of zinc are poisonous, but not to the same extent as those of lead. The oxide of zinc, used in painting as a substitute for white lead, is said to be capable of producing a colic, resembling that caused by lead, and called *zinc colic*. It attacks workmen exposed to the dust of the oxide while engaged in packing it in barrels, and yields to the remedies appropriate to the treatment of lead colic. (See *Chem. Gaz.*, Sept. 16, 1850.) This statement, however, is, to say the least, very questionable.

Pharmaceutical Uses. Zinc is never used as a medicine in the metallic state; but is employed in this state to prepare the officinal Acetate, Sulphate, and Chloride of Zinc, and the Reduced Iron of the Br. Pharmacopœia. In combination it forms a number of important preparations, a list of which, with their synonymes, is subjoined.

Zinc is employed medicinally,

I. In the metallic state.
   Zincum Granulatum, *Br.* — *Granulated Zinc.*

II. Oxidized.
   Zinci Oxidum, *U. S.*, *Br.* — *Oxide of Zinc.*
      Unguentum Zinci Oxidi, *U. S.*; Unguentum Zinci, *Br.* — *Ointment of Oxide of Zinc.*

   Zinci Valerianas, *U. S.*, *Br.* — *Valerianate of Zinc.* B.

ZINCI SULPHAS. *U. S., Br.*

Sulphate of Zinc. White Vitriol.

This salt was, at the late revision of the U. S. Pharmacopœia, transferred from the Preparations to the Materia Medica Catalogue, as an article to be purchased

of the manufacturer. The British Pharmacopœia gives the following process for its preparation.

"Take of Granulated Zinc *sixteen ounces* [avoirdupois]; Sulphuric Acid *twelve fluidounces* [Imperial measure]; Distilled Water *four pints* [Imp. meas.]; Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce* [avoird.], or *a sufficiency.* Pour the Acid previously mixed with the Water on the Zinc contained in a porcelain basin, and, when effervescence has nearly ceased, aid the action by a gentle heat. Filter the fluid into a gallon bottle, and add gradually with constant agitation the Solution of Chlorine until the fluid acquires a permanent odour of chlorine. Add now with continued agitation the Carbonate of Zinc until a brown precipitate appears; let it settle, filter the solution, evaporate till a pellicle forms on the surface, and set aside to crystallize. Dry the crystals by exposure to the air on filtering paper, placed on porous tiles. More crystals may be obtained by again evaporating the mother liquor."

Strong sulphuric acid has very little action on zinc; but, when it is *diluted,* water is instantly decomposed, and, while its hydrogen escapes with rapid effervescence, its oxygen combines with the zinc; and the oxide formed, uniting with the acid, generates the sulphate of the oxide of zinc. Thus it is perceived that *hydrogen* is a collateral product of the process. The proportion of the zinc to the strong acid in the process is as 4 to 5·53. The equivalent numbers give the ratio of 4 to 6·06; which indicates that the metal is somewhat in excess. If the materials are mixed at once, without any precaution, the effervescence of hydrogen is apt to be excessive, and to cause the overflowing of the liquid. This may be avoided by commencing the solution of zinc with a very dilute acid, which, as the action slackens, is made by degrees stronger and stronger, by the addition, at intervals, of small portions of fresh acid. As the zinc of commerce generally contains iron, this would contaminate the product, unless precautions were taken to prevent it. Hence the addition of chlorine, which reacts with the sulphate of iron to form tersulphate of sesquioxide of iron and sesquichloride of iron, which, upon the addition of the carbonate of zinc, yield the sulphuric acid and chlorine to the zinc; the sesquioxide of iron being deposited, and the carbonic acid set free. The former is separated by filtration, the latter escapes during the evaporation, the additional sulphate of zinc crystallizes with that first formed, and the chloride of zinc remains in the mother-waters.

Preparation on the Large Scale. Impure sulphate of zinc, as it occurs in commerce, is called *white vitriol.* It is manufactured by roasting *blende* (native sulphuret of zinc) in a reverberatory furnace. This mineral, besides sulphuret of zinc, contains small quantities of the sulphurets of iron, copper, and lead; and by roasting is converted, in consequence of the oxidation of its constituents, into sulphate of zinc, mixed with the sulphates of iron, copper, and lead. The roasted matter is then lixiviated; and the solution obtained, after having been allowed to settle, is concentrated by evaporation; so that, on cooling, it may concrete into a white crystalline mass, resembling lump sugar. In this state it always contains sulphate of iron, and sometimes a small proportion of sulphate of copper. It may be purified from these metals by dissolving it in water, and boiling the solution with oxide of zinc, which converts the sulphates of iron and copper, by precipitating their bases, into sulphate of zinc. The purified solution is then decanted or filtered, and, after due evaporation, allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under the impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on iron.

Properties, &c. Sulphate of zinc is a transparent, colourless salt, having a disagreeable, metallic, styptic taste, and crystallizing usually in small four-sided prisms. Its crystals have considerable resemblance to those of sulphate of magnesia. It effloresces slightly in dry air, and, though neutral in composition, reddens vegetable blues. It dissolves in two and a half times its weight of cold water, and in less than its weight of boiling water, and is insoluble in alcohol.

When heated it dissolves in its water of crystallization, which gradually evaporates; and, by a prolonged ignition, the whole of the acid is expelled, and the oxide of zinc left. Potassa, soda, and ammonia throw down a white precipitate of mixed oxide and subsulphate, which is redissolved by the alkali in excess. If iron be present, it is precipitated also, but not redissolved. The alkaline carbonates precipitate the metal in the state of white carbonate. Pure sulphate of zinc is precipitated white by ferrocyanide of potassium and hydrosulphuret of ammonia. What is thrown down by chloride of barium or acetate of lead (sulphate of baryta or sulphate of lead) is not dissolved by nitric acid. If copper be present, ammonia will produce a blue tinge; if iron, the ferrocyanide of potassium will cause a bluish-white precipitate instead of a white one, and tincture of galls a purple colour. Cadmium and arsenic may be detected by acidulating the solution with sulphuric acid, and passing a stream of sulphuretted hydrogen through it; when, if either of these metals be present, it will be thrown down as a yellow sulphuret. Sulphate of zinc is incompatible with alkalies and alkaline carbonates, hydrosulphates, lime-water, the soluble salts of lead, and astringent infusions.

The impure commercial variety of sulphate of zinc, called white vitriol, is in the form of irregular white masses, having some resemblance to lump sugar. The lumps usually exhibit, here and there on the surface, yellow stains, produced by sesquioxide of iron. It is less soluble than the pure salt, on account of its containing less water of crystallization.

Composition. Crystallized sulphate of zinc consists of one eq. of sulphuric acid 40, one of oxide of zinc 40·3, and seven of water 63 = 143·3. The white vitriol of commerce contains but three eqs. of water.

Medical Properties and Uses. This salt is tonic, astringent, and, in large doses, a prompt emetic. Before the discovery of tartar emetic, it was much employed to produce vomiting; but at present its use as an emetic is restricted principally to the dislodging of poisons, for which purpose its property of operating promptly renders it particularly suitable. As a tonic, it is supposed to be well suited to cases of debility, attended with irritation, being less heating than sulphate of iron. In dyspepsia it has been used with advantage in small doses, from a quarter of a grain to a grain, repeated several times a day; but, if good effects are not soon apparent, it should be laid aside. In the night-sweats of consumption it acts with singular efficacy, combined with extract of hyoscyamus, given at bedtime in the form of pill, composed of one grain of the salt to four of the extract. The combination has been used in these sweats, with the effect of arresting them in about thirty cases, by Dr. E. J. Coxe, of New Orleans. In obstinate intermittents it is a valuable resource, and may be given alone, or conjoined with cinchona or sulphate of quinia. But it is in spasmodic diseases, such as epilepsy, chorea, pertussis, &c., that it has been principally employed. Dr. Paris speaks of its efficacy in high terms, in spasmodic cough, especially when combined with camphor or myrrh, and "in affections of the chest attended with inordinate secretion." As an astringent it is chiefly employed externally. Its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in fluor albus and gonorrhœa, and as a collyrium in ophthalmia. In some conditions of ulcerated sorethroat, it forms a useful gargle. It has been employed also in solution with success as a remedy for nasal polypi, in the proportion of two scruples, gradually increased to an ounce of the salt, to seven fluidounces of water, applied by means of lint and by injection. The dose, as a tonic, is from one to two grains; as an emetic, from ten to thirty grains. To children affected with hooping-cough, it may be given in doses of from an eighth to a quarter of a grain two or three times a day. When used as a collyrium, injection, or gargle, or as a wash for indolent ulcers, from one to three grains or more may be dissolved in a fluidounce of water. For medicinal purposes the crystallized salt should be used, and in no case the impure white vitriol of commerce.

Prof. Simpson, of Edinburgh, has recently (1857) called attention to the value

of dried sulphate of zinc, in the form of powder, paste, or ointment, as a caustic. He attributes to it the advantages of being powerful, rapid, manageable, safe, and not deliquescent. In a recent paper he reports his successful use of it as a caustic in indurated inflammatory ulcers of the cervix uteri; in lupus; in ulcerous forms of skin diseases; in removing the small red sensitive tumours which form at the orifice of the female urethra, and in destroying ulcerated condylomata and warty excrescences. The dried salt should be finely levigated. The caustic paste is made by incorporating an ounce of the powder with a drachm of glycerin; and the caustic ointment, by thoroughly mixing the same quantity of the powder with two drachms of lard. (See *Am. Journ. of Med. Sci.*, April, 1857, p. 485.) Dr. Eben Watson, Surgeon to the Royal Infirmary of Glasgow, also bears testimony to the utility of dried sulphate of zinc as an escharotic. He particularly insists upon its advantages as a caustic application to callous ulcers, for the purpose of destroying their surface, exciting a new action, and disposing them to heal. The application causes severe pain, which should be relieved by opiates freely given, and continued until the sloughs separate, about the fifth day.

Sulphate of zinc, in an overdose, acts as an irritant poison. Besides vomiting and incessant retching, it produces anxiety, distressing restlessness, and extreme prostration. Few cases are on record of fatal poisoning by this salt; the patient being generally relieved by its prompt expulsion in vomiting. Four cases, however, have been reported in an Italian journal, two of which proved fatal. In one of the fatal cases, an ounce and a half had been swallowed by mistake for Epsom salt. The treatment consists in the free administration of bland drinks, the use of opium to allay irritation, and the employment of the usual antiphlogistic remedies, should symptoms of inflammation arise.

Gen. Ch. Flowers spathaceous. Inner limb of the *corolla* with one lip. *Anther* double, with a simple recurved horn at the end. *Germen* inferior. *Style* enclosed in the furrow formed by the anther. *Loudon's Encyc. of Plants.*

Zingiber officinale. Roscoe, *Trans. Linn. Soc.* viii. 348; Carson, *Illust. of Med. Bot.* ii. 55, pl. 98. — *Amomum Zingiber.* Willd. *Sp. Plant.* i. 6; Woodv. *Med. Bot.* p. 731, t. 260. The ginger plant has a biennial or perennial, creeping, tuberous root or rhizoma, and an annual stem, which rises two or three feet in height, is solid, round, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The flower-stalk rises by the side of the stem from six inches to a foot, and like it is clothed with oval, acuminate sheaths; but it is without leaves, and terminates in an oval, obtuse, bracteal, imbricated spike. The flowers are of a dingy yellow colour, and appear two or three at a time between the bracteal scales.

The plant is a native of Hindostan, and is cultivated in all parts of India. It is also cultivated in the West Indies, whither it was transplanted from the East, and at Sierra Leone in Africa. The flowers have an aromatic smell, and the stems, when bruised, are slightly fragrant; but the root is the portion in which the virtues of the plant reside. This is fit to be dug up when a year old. In the West Indies, the ginger crop is gathered in January and February, after the stems have withered. After having been properly cleansed, the root is scalded in boiling water, in order to prevent germination, and is then rapidly dried. Thus

prepared, it constitutes the ordinary ginger of commerce, or *black ginger*, as it is sometimes called from the darkish colour acquired in the process. It is imported chiefly from Calcutta, and is known to the druggists by the name of East India ginger; but recently considerable quantities have been brought from Africa, and some probably reaches us from the West Indies. In Jamaica another variety is prepared by selecting the best roots, depriving them of their epidermis, and drying them separately and carefully in the sun. This is called in the books *white ginger*, and is most highly valued. It reaches us from England, where it is said to undergo some further preparation, by which its appearance is improved. It is usually called in our markets *Jamaica ginger*. The root is also at present imported from the East Indies deprived of the epidermis. Considerable quantities are brought immediately from the West Indies in a recent state, and sold by the confectioners. A preserve is made from ginger by selecting the roots while young and tender, depriving them of their cortical covering, and boiling them in syrup. This is occasionally imported from the East and West Indies. When good it is translucent and tender.

The *recent root* is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light-ash colour with circular rugæ, internally yellowish-white and fleshy. It sometimes germinates when kept in the shops.

The *common* or *black ginger* is of the same general shape, but has a dark ash-coloured wrinkled epidermis, which, being removed in some places, exhibits patches of an almost black colour, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish and somewhat farinaceous. The powder is of a light yellowish-brown colour. This variety is most extensively used.

The *Jamaica* or *white ginger* differs in being entirely deprived of epidermis, and white or yellowish-white on the outside. The pieces are rounder and thinner, in consequence of the loss of substance in their preparation. They afford when pulverized a beautiful yellowish-white powder, which is brought from Liverpool in jars. This variety is firm and resinous, and has more of the sensible qualities of ginger than the black. The uncoated ginger of the East Indies resembles the Jamaica, but is darker. There is reason to believe that a portion at least of the white ginger of commerce has been subjected to a bleaching process, by which not only the exterior, but also the internal parts are rendered whiter than in the unprepared root. Trommsdorff found, in a specimen which he examined, evidences of the presence of chlorides, sulphates, and lime; and concluded that the bleaching was effected by chlorine, or by chloride of lime and sulphuric acid. Having macerated some black ginger in water, deprived it of the cortical portion, treated it for twenty-four hours with sulphuric acid diluted with nine times its weight of water, and finally placed it in a mixture of chloride of lime and water, in which it was allowed to remain for two days, he found it, upon being washed and dried, to present an appearance closely resembling that of the finest white ginger, both on the surface and internally. (*Annal. der Pharm.*, xvii. 98.) According to Brande, ginger is often washed in whiting and water; and Pereira states that it is sometimes bleached by exposure to the fumes of burning sulphur.

General Properties. The odour of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and are ultimately lost by exposure. The virtues of ginger are extracted by water and alcohol. Its constituents, according to M. Morin, are a volatile oil; a resinous matter, soft, acrid, aromatic, and soluble in ether and alcohol; a sub-resin insoluble in ether; a little osmazome; gum; starch; a vegeto-animal matter; sulphur; acetic acid; acetate of potassa; and lignin. The peculiar flavour of the root appears to depend on the volatile oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of pure white starch may be obtained from it. The volatile oil, examined by A. Papousck, was yellow, of the odour of ginger, and of a hot aromatic taste. Its sp. gr. was 0·893,

and boiling point 475°. Deprived of water by distillation with anhydrous phosphoric acid, it consisted of carbon and hydrogen, with the formula $C_{10}H_8$, and therefore belongs to the camphene series. (See *Chem. Gaz.*, Jan. 1, 1853, p. 12.) Papousek considers it a hydrate of camphene. (*Gmelin*, xiv. 70.) According to Zeller, one pound of the dried root yields one drachm and seventeen grains of volatile oil. (*Cent. Blatt*, 1855, p. 207.) Those pieces of ginger which are very fibrous, light and friable, or worm-eaten, should be rejected.

Medical Properties and Uses. Ginger is a grateful stimulant and carminative, and is often given in dyspepsia, flatulent colic, and the feeble state of the alimentary canal attendant upon atonic gout. It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. When chewed it produces much irritation of the mouth, and a copious flow of saliva; and, when snuffed up the nostrils in powder, excites violent sneezing. It is sometimes used as a local remedy in relaxation of the uvula, and palsy of the tongue and fauces. Externally it is rubefacient. It may be given in powder or infusion. The dose of the former is from ten grains to a scruple or more. The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluidounces. A fluid extract and oleoresin of ginger are now officinal, and very convenient preparations. (See *Extractum Zingiberis Fluidum* and *Oleoresina Zingiberis* in *Part* II.) The dose of the former may be from ten to thirty minims, of the latter from two to five minims. There is also an officinal tincture, the dose of which is about a fluidrachm.

PART II.

PREPARATIONS.

The preparation of medicines, which constitutes the art of Pharmacy, comes within the peculiar province of the apothecary. It is for his guidance that the various formulas of the Pharmacopœia have been arranged, and to him that their directions are especially addressed.*

A few general observations, therefore, of an explanatory nature, calculated to facilitate the progress of the pharmaceutical student, will not be misplaced under the present head. The duty of the apothecary is to obtain a supply of good medicines, to preserve them with care, to prepare them properly for use, and to dispense them. Our remarks will embrace each of these points.

The substances obtained from the mineral and animal kingdoms, and those furnished by the chemical manufacturer, are of a nature to admit of no general precepts as to their proper condition, which would not be suggested by the common sense of the purchaser. He must receive them as offered, and judge of their fitness for his purposes by his knowledge of the peculiar properties of each. The same remark applies to vegetable substances from abroad; but, with respect to indigenous plants, the apothecary is frequently called upon to exercise his judgment in relation to their collection and desiccation, and will derive advantage from some brief practical rules upon the subject.

Collecting and Drying of Plants. The proper mode of proceeding varies according to the nature of the part used. The different parts of plants are to be gathered at the period when the peculiar juices of the plant are most abundant in them. In the *roots* of *annual* plants this happens just before the time of flowering; in the roots of *biennials*, after the vegetation of the first year has ceased; and in those of *perennials*, in the autumn after vegetation has ceased, or in the spring before it has commenced. They should be washed, and the small fibres, unless they are the part employed, or unless experience has shown, as in the instance of podophyllum, that they are equally efficacious with the larger portion, should be separated from the fleshy solid part, which is to be cut in slices previously to being dried. *Bulbs* are to be gathered after the new bulb is perfected, and before it has begun to vegetate, which is at the time the leaves decay. *Barks*, whether of the root, trunk, or branches, should be gathered in the autumn or early in the spring. The dead epidermis, and the decayed parts, are to be separated. Of some trees, as the slippery elm, it is the inner bark only that is preserved. *Leaves* are to be gathered after their full devel-

* These preliminary observations to the second part of the work were originally prepared by Mr. Daniel B. Smith, then President of the Philadelphia College of Pharmacy. They have from time to time been considerably modified since their first appearance; but never to the same extent as in the edition preceding the present. The alterations then made were such as the improvements in Pharmacy suggested, and were deemed necessary to render the work a proper exponent of the existing state of knowledge upon the subject. The surviving author, while he alone is responsible for all that has been added to or modified in the work of Mr. Smith, so far as concerns arrangement and expression, has great satisfaction in acknowledging his indebtedness, for most valuable aid in the revision, to Professor William Procter, of the Philadelphia College of Pharmacy. So short a time has elapsed since the publication of the twelfth edition that comparatively few changes have been made in the present; but we have endeavoured not to pass over anything which appeared to deserve notice in this place. (*Note to the twelfth and thirteenth editions.*)

opment, before the fading of the flower. The leaves of biennial plants do not attain perfection until the second year. *Flowers* should in general be gathered at the time of expansion, before or immediately after having fully opened; and some, as the Rosa Gallica, while in the bud. *Aromatic herbs* are to be gathered when in flower; leaves, flowers, and herbs in clear dry weather, in the morning, after the dew is exhaled. *Stalks* and *twigs* are collected in autumn; *seeds* at the period of full maturity.

Vegetables should be dried as rapidly as is consistent with their perfect preservation. Those collected in the warm months, and during dry weather, may, except in a few instances, be dried by spontaneous evaporation in a well-ventilated apartment; and some, as roots and barks, may be exposed to the direct rays of the sun. In spring and autumn, and especially in damp, foggy, or rainy weather, the drying room should be artificially heated, and furnished with apertures near the top for the escape of the moist warm air, and others beneath in the direction of the prevailing wind, so as to command a current of air. The arrangements for supplying heat, which may consist of a small stove, or a drum connected with a stove in another apartment, should be capable of regulation; so that the temperature may range between 70° and 100° Fahr. at will. The substances to be dried should be supported on wicker or tinned wire hurdles, arranged horizontally above each other, so that the ascending and lateral currents of air may pass over and through every part. *Fibrous roots* may be dried in the sun, or at a heat from 65° to 80° in the drying room. *Fleshy roots* should be cut in transverse slices not exceeding half an inch in length, and, during the drying process, should be stirred several times to prevent moulding; the heat being at first maintained at about 100°. *Bulbs* must have the outer membranes peeled off; in other respects they are to be treated like fleshy roots. *Barks*, *woods*, and *twigs* readily dry in thin layers in the open air. *Leaves*, after separation from the stalks, should be loosely strewed over the hurdles, and their position changed twice a day till they become dry. When very succulent, they require more care in order to prevent discoloration. For dry and thin leaves the heat need not exceed 70°; for the succulent it may be gradually raised to 100°. *Annual plants* and *tops*, if not too juicy, may be tied loosely in small bundles, and strung on lines stretched across the drying room. *Flowers* must be dried carefully and rapidly so as to preserve their colour. They should be spread loosely on the hurdles, and turned several times by stirring. When flowers or leaves owe their virtues to volatile oils, greater care is necessary. *Succulent fruits*, as berries, may be dried, when in bunches, by suspending them in the drying room.*

The following table, taken from the Edinburgh Dispensatory, presents the amount yielded by 1000 parts of the vegetables respectively mentioned, after being dried.

Root of Angelica Archangelica	263	Leaves of Digitalis purpurea	180
Aspidium Filix Mas	500	Hyoscyamus niger	135
Inula Helenium	187	Melissa officinalis	220
Valeriana sylvestris	316	Salvia officinalis	220
Bark of the Oak	410	Tops of Mentha piperita	215
Elder	292	Flowers of Anthemis nobilis	338
Elm	375	Borago officinalis	96
Twigs of Solanum Dulcamara	308	Lavandula vera	510
Leaves of Atropa Belladonna	140	Sambucus Ebulus	256
Conium maculatum	185	Petals of Papaver Rhœas	84
Datura Stramonium	110	Rosa rubra	330

* It is sometimes very difficult to dry glutinous substances, such as gum in its various forms, so as to preserve the original appearance; as the particles are apt to adhere together, and give rise to amorphous masses more or less solid and translucent. To obviate this, Reischauer proposes to effect the drying in an ethereal medium, in which ether takes the place of the removed water, and prevents the adhesion of the particles. A well-closed glass vessel is filled with ether or other similar fluid, with chloride of calcium, quicklime, or other desiccating agent at the bottom. The substance to be dried is placed in a shallow saucer below the surface of the ether. The rationale of the operation is simply that, as the drying agent absorbs water from the ether, this absorbs it from the

PRESERVATION OF MEDICINES. The proper preservation of medicines is an object of the greatest importance to the apothecary. The apartment destined for a store room should be quite dry, and capable of being ventilated at will, and protected from vermin. As a general rule, drugs should be excluded from the light, and not packed away until thoroughly dry. New parcels should not be put in old receptacles until these have been examined, and freed from dust and insects. Barrels and boxes, well fitted with movable covers, are suitable for most roots, barks, and woods, and for some herbs, leaves, and seeds. They should be painted externally, and are less liable to harbour insects when varnished inside with a solution of shellac, imbued with aloes, wormwood, or colocynth. *Roots* and *bulbs* which are to be preserved fresh, should be buried in dry sand. *Aromatic leaves* and those containing alkaloids, *flowers*, most *seeds*, and some *roots* especially liable to the attacks of insects, should be kept in tin canisters, or in light boxes lined with lead, tin, or zinc, or in opaque glass or earthenware vessels. Double-cased tin vessels are admirably adapted to the preservation of vegetables. These should be frequently examined in order to prevent deterioration from insects or moisture. When insects are discovered in a drug, the best means of destroying them, according to Lutrand, is to suspend an open vial containing chloroform in the canister, which is to be closed securely, so that the atmosphere of the vessel may become saturated with the vapour. Cantharides and ergot may be thus treated. The presence of a little ether in the bottle has often also great effect in preventing the attacks of worms; and benzole, carbolic acid, and bisulphide of carbon may be employed for the same purpose. Bundles of aromatic herbs, the leaves of which are very friable, as sage, marjoram, &c., should be wrapped loosely in refuse paper, so as to preserve a due proportion between stems, leaves, and flowers. *Gum-resins*, unless in original packages, should be kept in earthen jars or tinned boxes; *fixed* and *volatile* oils, in canisters or bottles closely stopped, in a cool dark place, where the average temperature is about 60°. Substances in the form of fecula should be kept in oak barrels, or in canisters, and carefully examined from time to time to detect and remove insects.

GARBLING OF DRUGS. Drugs frequently require to be garbled before they are in a proper state for use. *Senna* is to be separated from the stalks and legumes; *cetraria* from moss, leaves, and sticks; *myrrh* from bdellium, &c.; *gum Senegal* from Bassora gum and a terebinthinate resin; *flaxseed* from clover and garlic seed; *seneka* from ginseng; *spigelia* from the stems and leaves, and both it and *serpentaria* from adhering dirt. Seroons of cinchona should be examined, and the barks assorted before they are put by for use. *Gums* and *gum-resins* should be garbled, and the tears preserved separately.

WEIGHTS AND MEASURES. A precise acquaintance with the recognised measures of weight and capacity is essential to the operations of the apothecary. The weights used by him in compounding medicines, and dispensing them by prescription, are the troy pound and its divisions; those by which he buys and sells commercially, the avoirdupois pound and its divisions. The former contains 5760 grains, the latter 7000 grains; so that 11 troy pounds are nearly equivalent to 9 pounds avoirdupois. The troy pound contains 12 ounces of 480 grains; the avoirdupois pound 16 ounces of 437½ grains; eleven of the former being nearly equal to twelve of the latter. The troy ounce is divided, for the use of the apothecary, into 8 drachms of 60 grains each; and the drachm into 3 scruples of 20 grains each. The United States Pharmacopœia recognises the troy weights, but employs only the grain and ounce, and, to prevent confusion, designates the latter weight by the name of *troyounce;* and whenever, in this work, any term is used expressive of weight, when not otherwise stated, it is to be understood as being of the denomination of troy weight. The

substance to be dried, until the latter is sufficiently deprived of it. This of course parts with the ether absorbed by subsequent evaporation. It is obvious that the process is applicable only to bodies which are insoluble in ether, or in any fluid that may be substituted for it. (*Chem. News*, March 16, 1866, p. 123.)—*Note to the thirteenth edition.*

British Pharmacopœia employs the avoirdupois pound and ounce, and the troy grain.

The measures used by the apothecary, in this country, are the wine pint and gallon. The wine pint contains 28·875 cubic inches. The weight of a pint of distilled water, at 62° Fahrenheit and 30 inches of the barometer, is 7289·7 grains, or 1 pound 3 ounces 1 drachm 29·7 grains troy, or 1 pound 289·7 grains avoirdupois. The gallon is divided into 8 pints, the pint into 16 fluidounces, the fluidounce into 8 fluidrachms, the fluidrachm into 60 minims. The weight of a fluidounce of water is 455½ grains, being 18 grains more than an avoirdupois ounce. A drop is generally though incorrectly considered as equivalent to a minim. Drops vary in size according to the nature of the fluid, and the size and shape of the lip from which they fall. A drop of water nearly equals a minim. A fluidrachm of antimonial wine will make, on an average, about 72 drops, one of laudanum 120 drops, one of alcohol 138 drops, one of ether 150 drops, and one of chloroform more than 200 drops. For a table showing the relative value of minims and drops, see the *Appendix*. The U. S. Pharmacopœia recognises the wine measure as here given, but, in its processes, employs only the pint and its subdivisions, omitting the use of the gallon altogether. The measures recognised by the British Pharmacopœia are the Imperial gallon of 70,000 grains of distilled water, or 277 cubic inches, and its divisions. This gallon is divided into 8 pints of 20 fluidounces each. The fluidounce is divided as that of wine measure, but differs from it in value, containing precisely an ounce avoirdupois (437·5 grains) of distilled water. Measures are employed, both in the U. S. and Br. Pharmacopœias, to express the quantity of liquids in most of their formulas; but, in reference to the stronger acids, chloroform, and the fixed oils, weights are now generally preferred.

Liquids are to be dispensed from graduated measures, of which those holding from a fluidounce to a pint are hollow inverted cones; and those holding a fluidrachm, and graduated to every five minims, are cylindrical. For smaller quantities than five minims, a slender tube holding a fluidrachm may be used, having the aliquot parts divided off, and marked with a diamond. Alsop's minimeter, which consists of a slender glass syringe graduated into sixty parts, each equal to a minim, is the most convenient and accurate instrument for measuring fractions of a fluidrachm. Care should be taken to verify these instruments. This may be done by reference to the table in the *Appendix*, in which the value of each division of measure is given in grains; distilled water at 60° F. being the standard. The following approximate measures are used in prescribing medicines; viz., a wineglassful containing two fluidounces, a tablespoonful half a fluidounce, a dessertspoonful two fluidrachms, and a teaspoonful a fluidrachm.*

Specific Gravity. The specific gravity of liquids affords one of the best tests of their purity. The instrument commonly used by the apothecary for ascertaining this is *Baumé's hydrometer*. This is a glass bulb loaded at one end, and drawn out at the other into a tube on which the scale is marked. That used for alcohol is graduated by loading it until it sinks to the foot of the stem (which is marked zero) in a solution of one part of common salt in nine parts of water. It is then put into water, and the place to which it sinks marked 10° of the scale, which is constructed from these data. The hydrometer for liquids heavier than water is made by loading it, so that in distilled water it shall sink nearly to the top of the stem. The place to which it sinks in a solution of 15 parts of salt in 85 parts of water is then marked 15°, and the scale divided off. For a table exhibiting the value of these scales in specific gravities, see the

* A patented glass measure is made, in Philadelphia, by Mr. William Hodgson, Jr., which, besides peculiar advantages in its graduation, would appear to have the great merit of being uniform, as it is cast in moulds. The measures imported from England are graduated in accordance with the subdivisions of the Imperial pint, and are not applicable to American pharmacy. For a similar reason those brought from Germany are generally unfit for use in our shops. Every apothecary should satisfy himself of the accuracy of the measures he employs. By possessing one on which he can rely, he can use it to determine the correctness of others.

Appendix. Hydrometers are made specially for syrups, acids, and saline solutions. Those for syrups should have a very short tube, graduated from 20° to 40° of Baumé's scale for heavy liquids The advantage of a short stem is, that the instrument may be used in small vessels.*

The hydrometers commonly imported are so carelessly made that scarcely any two will agree, and little dependence can be placed on their accuracy. A more certain method consists in weighing the liquid at a uniform temperature in a bottle, the capacity of which, in grains of distilled water, has been previously ascertained. If a bottle be selected which will hold exactly 1000 grains of water at 60°, the weight in grains of the quantity of any liquid which it will hold, will be the specific gravity of that liquid. Such bottles are sold in the shops. If one is not attainable, an ordinary vial may be used, and the specific gravity obtained by dividing the weight of the liquid examined by the weight of the water. The operation is rendered more accurate by fitting a smooth cork to the vial, passing a pin transversely through it so as to rest on the lips of the vial, and then cutting a small vertical groove into the side of the cork, so as to admit of the escape of the excess of liquid when the cork is inserted.

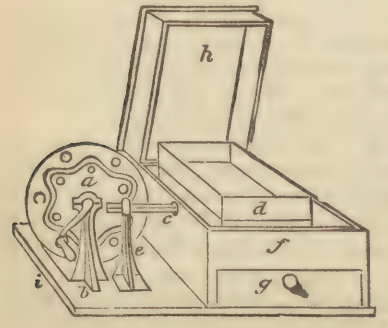
Gay-Lussac's centesimal alcoholmeter is a very useful instrument, being graduated so as to indicate the percentage by measure of absolute alcohol in any mixture of pure spirit and water; but unfortunately the commercial instruments are too often inaccurate.

The specific gravity of a solid is ascertained by first weighing it in air and then in water, and dividing the former weight by the difference between the two. If lighter than water, it should be first weighed in the air, then in air and in water in connection with a heavier body, which has itself been previously weighed in air and in water; and the weight of the lighter body in the air, should be divided by the excess of the difference between the weights in air and water of the two conjoined, over that of the weights in air and water of the heavier body alone. If the body be soluble in water, its relative weight to that of some other liquid of known specific gravity should be ascertained, in the manner above directed, and this weight multiplied by the specific gravity of that liquid.

The specific gravity of insoluble powders heavier than water, as calomel, may be obtained by introducing 100 grains into a thousand-grain bottle, adding first a little distilled water and thoroughly agitating, with the thumb over the orifice, so as to rid the solid particles of adherent air, then filling the bottle accurately with more of the water, ascertaining the weight of the contents in grains, subtracting the number of grains, exceeding 1000, from the weight of the powder in air, and dividing the latter by the difference. When the powder is soluble, or lighter than water, another liquid, as alcohol, ether, or oil of turpentine, may be used, the necessary allowance being made for the difference in specific gravity. Very accurate thousand-grain bottles are now made in Philadelphia.

Mechanical Division. One of the simplest methods of preparing medicines is their reduction, by mechanical means, to a state of minute division. This is effected by the operations of slicing, bruising, rasping, filing, triturating, grinding, sifting, levigation, and elutriation. When the result is a fine powder, the process or processes employed are called *pulverization.*

The more important drugs which are sold in the state of powder are pulverized by persons who pursue that occupation for a livelihood. Owing to the readiness with which fraud can be perpetrated in this operation, the apothecary cannot be too careful to place his drugs in honest hands. In sending drugs to the powderer a certain percentage of powder is sometimes required, without



* For some interesting observations in reference to the inaccuracy of the existing tables of specific gravities corresponding to the several degrees of Baumé's hydrometer, to the uncertainty of the hydrometer in use, and to a mode of remedying these inconveniences, the reader is referred to a paper by Mr. Henry Pemberton in the *Am. Journ. of Pharm.* (xxiv. 1), and, for a good and accurate method of graduating hydrometers, to a communication from Dr. W. H. Pile, in the same journal (xxiv. 310). It may be useful to physicians practising in the country, and to apothecaries, to know that reliable hydrometers and other instruments are kept for sale, at this time (A. D. 1864), by Dr. Pile in Philadelphia.

regard to the condition of the drugs, as to moisture, extraneous admixture, &c., which percentage often cannot be obtained without the addition of foreign matter. This procedure on the part of the druggist is one of the chief sources of dishonesty of the powderer, and is highly reprehensible. The loss of weight during the processes of pulverization is due to the evaporation of moisture, the unavoidable escape of dusty particles, and the useless residue called *gruff's*. We have been informed that it is not customary, with the powderers in this country, to reject the less active and less readily pulverizable constituents, as the ligneous parts of certain roots, but to continue the process till almost the whole will pass through the sieve. The following statement has been abbreviated from a table prepared by MM. Henry and Guibourt. One thousand parts of the substances mentioned yielded, when pulverized—*

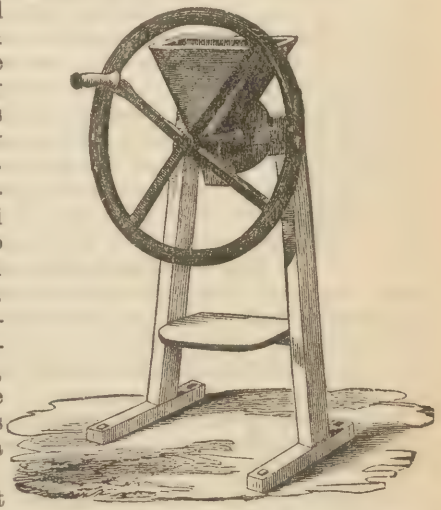
The apothecary often finds it necessary to pulverize drugs in small quantities. For this purpose he should be provided with *mortars* of iron, brass, Wedgwood ware, glass, and marble, sieves of several degrees of fineness, at least one hand-mill, one or more cutting knives, a rasp, and a pair of pruning shears.



Contusion should be performed in an iron or brass mortar, the latter being used for astringent substances. The curve of the interior surface of the bottom should be elliptical, and that of the pestle should be of the same kind, but of shorter radius, so that, when the pestle stands vertically in the mortar, their surfaces may approximate pretty closely for some distance around the point of actual contact. Powdering by contusion is much facilitated by using a large mortar, with the pestle suspended on a spring so as to assist in elevating it. In powdering acrid substances, as well as to prevent loss in those that are dusty, a leathern cover should be attached to the pestle, and held tightly around the edge of the mortar by a circular wooden frame. The operator should guard himself against the fine particles of very acrid substances, like cantharides, euphorbium, &c., by standing with his back to a current of air, and covering his nostrils with a wet cloth. He should be careful not to impede the process by introducing too large a quantity of the material, so as to clog the pestle. After the pestle has been in action a certain time, the fine particles accumulate so as to hinder the reduction of the

* We are told that, in consequence of improvements in drug mills, the loss in powdering is less than formerly; and what occurs is due mainly to the loss of moisture in drying previously to the pulverization. We refer for a table giving the percentage of loss in powdering, of many medicines, prepared by Mr. Thos. J. Covell, of Brooklyn, New York, to the *Am. Journ. of Pharm.* (March, 1867, p. 116).—*Note to the thirteenth edition.*

coarser. At this point the sieve should be brought into requisition *Sieves* for powders are constructed of woven brass wire, and silk cloth (bolting cloth). The best arrangement for the apothecary's use is that known as the box or drum sieve, being cylindrical, with a cover above, and a receptacle below for the powder. After introducing the contents of the mortar, a jerking circular motion should be given to the sieve, without much jarring, so that none but the finest particles may pass. The coarser portion should then be returned to the mortar to be again acted on. A set of simple sieves, formed by tacking pieces of woven wire, with meshes varying from the sixtieth to the fourth of an inch, to square wooden frames, should be provided to prepare drugs for percolation and other modes of solution. When the quantity of material to be sifted is large, recourse may be advantageously had to *Harris's patent sieve*, which has the merits of the drum sieve, with great facility of use. (See *Am. Journ. of Pharm.*, xxv. 31.) A figure of this instrument is given in the margin of the preceding page.

Grinding. The hand-mill is exceedingly useful for the coarse comminution of drugs, especially of those which, from their acrimony, may annoy the operator in the process of contusion. *Swift's drug mill* is one of the most useful and manageable of the kind. It does not answer well for fibrous drugs like slippery elm and sarsaparilla, unless sliced transversely in short sections.

Trituration is the effect produced where a circular motion, accompanied by pressure, is communicated to the pestle; and is applied most generally to friable substances, or to powders obtained by other means, with a view to their further and more regular comminution The operation is accelerated by alternately increasing and diminishing the circular movements, so as to bring the pestle in contact with all parts of the surface of the mortar. Dover's powder and red oxide of mercury are instances requiring this operation; and in prescriptions for powders, where different substances of variable molecular condition are associated, this process is employed to bring them to a uniform state of division.

Levigation, or *porphyrization* as it was formerly called, is a kind of trituration effected between the flat surfaces of a slab and muller. As the surfaces are equidistant at all parts, a substance, subjected to their action, has its particles more uniformly divided than between the surfaces of a mortar and pestle. It is usual to moisten the powder with water or alcohol (in which it should be insoluble) so as to bring it to a pasty consistence. The slab and muller are made of glass, porphyry, Wedgwood ware, or marble.

Elutriation bears the same relation to trituration and levigation that sifting does to contusion. It consists in agitating a powder, obtained by those processes, in a large quantity of water, allowing the coarser particles to subside, and pouring off the supernatant liquid, holding the finer particles in suspension, that they may settle separately. The pasty thick mass, left when the clear liquid is decanted, is put into a funnel, and dropped in small portions on a chalk stone so as to form small conical masses. The fineness of the powder depends on its specific gravity, and on the length of time which elapses before the liquid from which it subsides is drawn off.

Various means are used to facilitate powdering. All vegetable substances must be carefully and thoroughly dried. No part of the business of the powderer requires more care than this, especially in relation to substances which owe

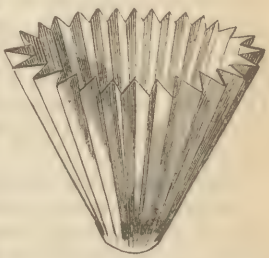
their activity to volatile principles. The heat derived from steam, regulated below 100° for aromatic substances, and below 140° for others not injured thereby, is the most appropriate. Resins, gum-resins, and gums must be powdered in cold frosty weather. Tragacanth and nux vomica must be dried by a stove heat, and powdered while hot. The fibrous roots, as liquorice and marshmallow, should be previously cut into thin transverse slices. Agaric is to be beaten into a paste with water, then dried, and triturated. Cloves and the aromatic seeds may be ground in a hand-mill, and afterwards triturated. Squill and colocynth, the comminution of which is sometimes aided by soaking them in mucilage of tragacanth and then drying, are best powdered in a dry atmosphere, after having been thoroughly dried by a stove heat. Camphor requires the addition of a few drops of alcohol. The efflorescent salts may be obtained in the state of fine powder by exsiccation; and those which are insoluble in alcohol may be precipitated by it, in impalpable powder, from their aqueous solutions. Vanilla, mace, and other oily aromatic substances, may be rubbed to powder with sugar; magnesia and white lead, by friction on a wire sieve.

Care should be taken, in powdering, to separate previously the inert portions and impurities, and to mix intimately the whole of the powder which is reserved for use. The central woody fibre of ipecacuanha and of other roots, the virtues of which reside in the bark, is to be rejected. The first portions of those barks to which lichens and the dead epidermis adhere, are inert; as are also the last particles of the fibrous roots and barks.

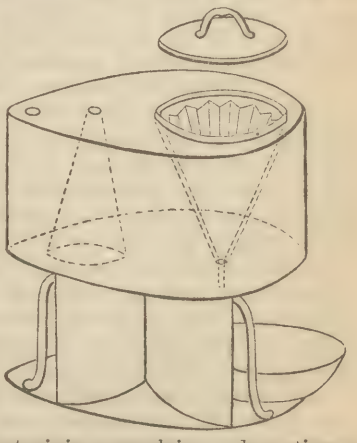
Ivory, horn, nux vomica, wood, and iron are prepared for pharmaceutic purposes by filing and rasping; guaiacum wood and quassia by turning in a lathe; roots, stalks, and dried herbaceous plants by cutting with a large pair of shears, or with a large knife, fixed in a frame at one end, and furnished with a long handle at the other. Tin and zinc are granulated by melting them, and strongly agitating while they are cooling; and carbonate of potassa, by stirring with an iron rod the concentrated solution as it concretes. Earthy insoluble substances are conveniently reduced to powder by levigation.

Powders, as obtained by levigation, elutriation, precipitation, &c., often require to be dried. The process of drying may generally be effected by exposure to a dry air, aided or not by a moderate heat; but it is much facilitated by the action of absorbent substances, such as bibulous or unsized paper, porous bricks, &c. A convenient method is to spread the powder on brick-tiles, covered with a double layer of bibulous paper.

Separation of Mixed Substances. Various mechanical operations for this purpose are resorted to in practical pharmacy. Some of these relate to the separation of solids from liquids, others to that of one liquid from another.

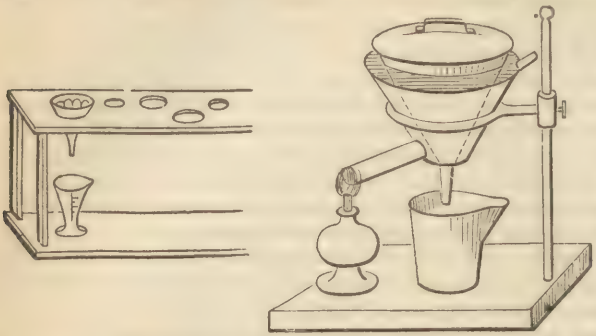


Separation of Solids from Liquids. This includes the processes of decantation, filtration, percolation, straining, expression, clarification, &c.



Decantation. Solids may be separated from liquids, when there exists no chemical action between them, by being allowed to subside. The supernatant liquid may then be carefully poured off; or it may be drawn off by a syphon, or separated by filtering. The last operation, or expression by a stronger force, is necessary to separate the whole of the liquid; but decantation should always be employed when appropriate, as much time is thus saved in filtering.

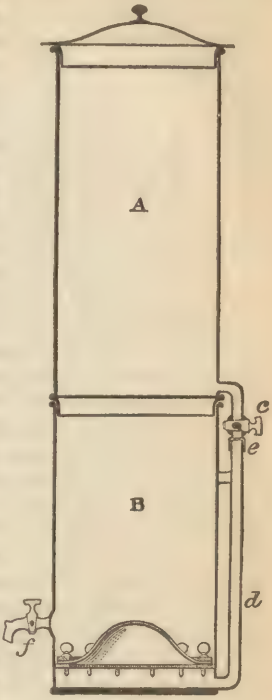
Jars larger at bottom than at the top, and furnished with a lip for pouring, called *precipitating jars*, are sold in the shops, and are proper for decantation, precipitation, and the receiving of filtering liquids. When the decanted liquid is the object of the process, and the powder subsides very slowly, the precipitation may be greatly hastened by the addition of a small quantity of solution of gelatin. Decantation by pouring is facilitated by holding vertically against the lip a glass rod, which attracts and directs the current, and prevents it from running down the sides of the vessel. The syphon is a tube bent like the letter U, having one limb longer than the other. When it is filled with liquid, and the shorter end is inserted in the fluid to be decanted, a current is established towards the longer limb, owing to the greater weight of its contents, and continues as long as the shorter limb is kept below the surface of the liquid.



Filtration consists in pouring a mixture of solid and liquid matter on a porous surface, called a filter or strainer, which admits of the passage of the fluid only, and is designed either to clarify the liquid, or to separate the solid from the associated liquid by washing and draining.

Filters or strainers are made of unsized paper, muslin, linen, or woollen cloth, charcoal, glass, and sand. The apothecary should be provided with several kinds of filtering paper, one of which should be white and free from matter soluble in dilute acids, especially oxides of iron. A *charcoal filtering paper* is now made, which serves the double purpose of clarifying and decolorizing liquids. It is prepared either by incorporating powdered animal charcoal with the pulp out of which the paper is made, or placing it, in the process of manufacture, between two layers of the pulp. As the charcoal diminishes the cohesion of the paper, a sheet of gauze is inserted in each piece, or in the centre of each piece, when used as a filter, in order to give it strength at the apex when folded. (*Am. Journ. of Pharm.*, xxx. 586.) Paper filters are *plain* or *plaited*. The plain filter is made by folding a square piece of paper twice, so as to bring the four corners together, and then separating one of the layers from the other three so as to form a hollow cone, which is inserted in a funnel. Such filters are best for precipitates; but, when rapid filtration is required, the plaited filter, by presenting a much greater extent of surface, and numerous channels for the descent of the liquid, is to be preferred. The paper is folded into 32 triangular surfaces, all the points meeting in the centre, and the edge presenting a zigzag outline as in the figure. In some cases it may be necessary to place a small cone of the same material outside of the large one to strengthen it. Paper manufactured for filtering should be made in square, instead of oblong sheets, as much waste might be thus prevented. Paper in a circular form, and of various sizes, prepared expressly for filtering, is now imported from France. When the liquid is too viscid to pass readily through paper, a cotton or woollen bag of a conical shape may be used. Cotton flannel with a thick nap is well suited for syrups. Acids may be filtered through a layer of fine siliceous sand, supported in the neck of a glass funnel by pieces of glass gradually decreasing in size. M. Boettger, having noticed that pyroxylin is attacked only by ethereal liquids, proposes to employ it in the filtration of corrosive liquids, such as the strong acids, concentrated solution of permanganate of potassa, &c. The pyroxylin is introduced in the form of a plug at the neck of the funnel. (*Journ. de Pharm.*, Juin, 1860, p. 472.) Castor oil, syrups, and oxymels may be filtered through coarse paper, made entirely of woollen shreds; but the best material for fixed oils is hatter's felt, in the conical form in which it is prepared in the making of hats. This may be attached to a tin ring, and suspended over a suitable vessel. Melted fats, resins, wax, and plasters may be *strained* through muslin stretched over a square frame, or a hoop. Hair cloth or wire gauze is better suited for plasters than muslin. Small sieves of fine bolting cloth serve for straining emulsions, decoctions, and infusions; and a temporary strainer of this kind may be made by fastening a piece of muslin between the upper and lower parts of a common wooden pill box, and then cutting off the ends so as to leave the rim only of the box around the muslin. The filtration of viscid substances is facilitated by heat. Filtration through bone-black is practised for muddy or dark coloured liquids. Much inconvenience is often experienced in the filtration of hot saturated saline

solutions, by the cooling of the liquid, and consequent crystallization of the salt, in the filter and neck of the funnel. To obviate this, the tin apparatus represented in the wood-cut on the preceding page was contrived by Dr. Hare. The vessel is filled with hot water, which is kept at a boiling heat by a spirit lamp placed under the cavity having the shape of an inverted funnel. A glass funnel with a filter is placed in the other cavity, and the liquid passes through rapidly. In filtering alcoholic solutions, it is necessary to protect the liquid from the flame of the lamp, and for this purpose the partition underneath has been added. No apothecary should be without this useful apparatus. The arrangement of Dr. Hare has been simplified by having a funnel with double sides, as in the figure, with a hollow cylindrical projection at the lower part, to which a spirit lamp heat may be applied, while the funnel is supported on a lamp stand; the space between the sides being filled with water. Frames of various sizes for holding funnels and filters will be found useful. The wood-cut represents the one commonly used. The efflorescence of saline solutions on the edge of the filtering paper may be prevented by dipping it in melted tallow or lard.



The filtration of liquids which are altered by exposure to the air requires much caution. A very simple method of accomplishing it is to insert a slender tube of glass into the funnel, long enough to reach below the neck, while the upper part is nearly as high as the top of the funnel. The space between the tube and the neck must be filled with bits of glass and fine sand so as to form a good filtering bed; the liquid is then poured in, and the top of the funnel covered with a plate of glass. If this be luted on, and the funnel luted into the neck of a bottle, the process will be performed with perfect accuracy. Another way of performing this operation, in relation both to liquors altered by the carbonic acid of the air, and to those which are very volatile, as ethereal and ammoniacal solutions, consists in covering the funnel with a sheet of tin-foil, or moist bladder, and putting a small tube within and against the side of the funnel, extending nearly to the top, so as to form a communication between the atmosphere of the receptacle and that of the funnel. By such an arrangement ordinary filtering through paper can be conducted with perfect success with ether or solution of ammonia. The filtration of large quantities of liquids is facilitated by having a self-supplying apparatus, so that the level of liquid in the filter may be constant. This is effected by inserting a tube, with a bore of a quarter of an inch, through the cork of a large bottle containing the liquid to be filtered, and supporting the bottle in an inverted position over the filter, as at page 933, so that the tube shall dip slightly below the surface of the liquid. As this descends, its place is supplied from the bottle above. Another arrangement, in which a syphon is used, is figured in page 920.*

In filtering in the ordinary method, much embarrassment is often experienced, especially with viscid substances, such as fixed oils, in consequence of the collection of the solid matters at the bottom of the funnel, offering a constantly increasing impediment to the passage of the liquid. This is obviated by *filtering upwards*. Some years since, Professor Procter contrived an instrument for this purpose; and more recently a very ingenious apparatus has been invented

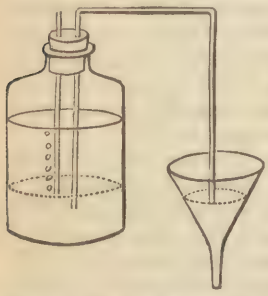
* For the figure and description of an apparatus for continuous filtration, applicable also, with some modification, to the washing of precipitates, see a paper, by Mr. Henry B. Brady, in the *Pharmaceutical Journal and Transactions* (Oct. 1868, p. 216).

by Mr. Wm. R. Warner, which combines the advantage of upward filtration, with that of applying heat to maintain a due degree of fluidity in the liquid filtered; both very desirable objects in the filtration of fixed oils. A wood-cut is given in the margin, copied from that of Mr. Warner, in the *American Journal of Pharmacy* (Jan. 1861, p. 13). The instrument consists essentially of two cylindrical vessels of tinned iron, one placed on the top of the other; the upper one (A) about 22, the lower (B) 18 inches in height, and both about 10 inches in diameter. The two communicate by means of a tube (*d*) proceeding, on the outside, from near the bottom of the upper vessel, and entering through the side of the under one near the bottom, into a compartment, separated from the upper portion of the vessel by a diaphragm formed of hatter's felt. This is secured, at its circumference, between a projecting ledge of tinned iron soldered to the sides of the vessel, and a ring of the same material fastened to it by screws. The tube is made in two pieces so as to allow the vessels to be separated, and is provided with a stop-cock (*c*) near the top. The lower vessel has an outlet (*f*) near the bottom of its upper compartment, which is also provided with a stop-cock. When the instrument is used, the oil is introduced into the upper instrument at top, where it is furnished with a lid, and the stop-cock of the tube is opened, so that the liquid shall pass through the tube into the lower compartment of the lower vessel. By the pressure of the column of liquid it is thus forced upward against the diaphragm of felt, which, being porous, allows its passage through into the upper compartment, where the clarified liquid accumulates and whence it may be drawn off through the lower stop-cock. The instrument may be placed upon a stove, in order to maintain such a heat as may be deemed advisable. The filtered liquid should be drawn off occasionally, so as not to interfere with the passage of additional portions through the felt.

A simple apparatus for hastening filtration has been proposed by Dr. Picard, consisting of a precisely conical funnel, connected, by means of an elastic joint, with a glass tube not more than a foot in length, and straight except near its upper end, where it makes a complete turn upon itself, the effect of which is to act as an aspirator, and hasten the movement of the fluid through the tube. It is important that the filtering paper should lie, wetted, in close contact with the glass, so as not to admit a bubble of air between them. The rate of filtration is said to be thus accelerated, so as to be ten or twelve times more rapid than when an unbent tube is used. (*Chemical News*, Jan. 12, 1866, p. 23.)*

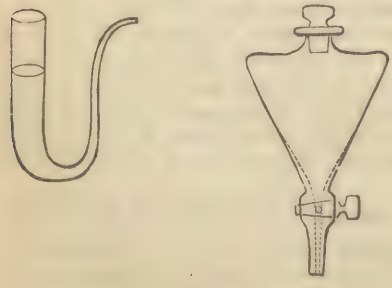
Expression is required to separate the last portions of tinctures and infusions from the dregs. A screw-press is used for this purpose. The substance to be pressed is put into a cylinder of strong sheet tin, the sides of which are pierced with small holes. This is placed on a square tray of tin having a lip for pouring. A block of wood, which fits into the cylinder like a piston, is placed on the top, and the whole is put under the screw-press, the pressure of which is gradually brought to bear upon it.

This press is to be used for expressing the juices of fresh plants, which must



* For a description, with figures, of an apparatus invented by Mr. A. B. Spencer, of Rochester, N. Y., intended to facilitate filtration, on a small scale, by the production of a partial vacuum in the receiving vessel, thus bringing atmospheric pressure to bear on the passing fluid, see a paper by Mr. Ed. Parrish, in the *American Journal of Pharmacy*, March, 1866, p. 107; from the *Proceedings of the Am. Pharm. Association*, A. D. 1865. (*Note to the thirteenth edition.*)

be previously well beaten in a mortar, water being added to those which are hard and dry. The juices of succulent fruits, as strawberries, raspberries, &c., are most advantageously extracted by filling several strong flannel bags about two-thirds full, without bruising them, laying these in a pile on a tray, placing a strong block over the whole, and gradually bringing the press to bear upon them. The expressed oils are obtained by bruising the seeds which contain them, and enclosing the bruised mass in strong bags, which are placed in a firm hollow frame, and subjected to strong sudden pressure by driving up a wedge. Expressed oils are clarified from mucilage by boiling them with water.



A small hydraulic press has been constructed, in which oil is used instead of water, so as to avoid the breaking of the instrument that might result from the freezing of the water in winter. (See *Proceed. of the Am. Pharm. Assoc.*, 1864.)

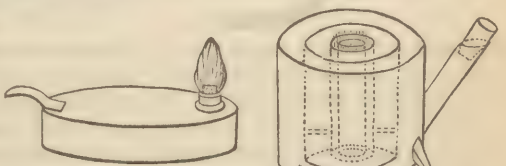
The *clarification* of liquids may be effected by the addition of some coagulable substance, such as milk or an aqueous solution of ichthyocolla. The white of an egg beaten up with water will coagulate with a gentle heat, and clarify any liquid with which it is mixed. The vegetable acids will clarify many of the expressed juices; and the juice of sour cherries will cause the complete separation of the pectin of currant and raspberry juice, so as to fit them for syrups.

Precipitation is sometimes mechanical, as in the *levigating* and *elutriating* of chalk, and sometimes chemical, as in the preparation of the precipitated carbonate of lime by decomposing chloride of calcium. When a precipitant is directed to be added until no further precipitation takes place, the fact may be ascertained by taking a drop of the liquid on a glass plate, and trying it with the precipitant. The formation of a precipitate is often much assisted by agitation, or by heat. The separation of the supernatant liquid from the precipitate is most effectually accomplished by means of a syphon. When the liquid is a saline solution, it is necessary to wash the precipitate until the water exhibits no trace of the salt. In doing this, great care must be taken to select the purest and clearest water, and the ultimate drying of the precipitate must be performed in a filter, or on a porous stone.

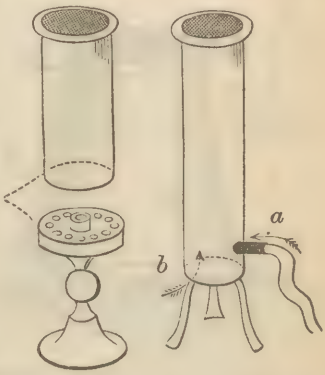
The apparatus figured in the margin is very convenient for procuring a constant and gentle stream of water, in washing precipitates, and in clearing crystals of the impurities of their mother-water. It consists of a syphon having legs of equal length, one of which is inserted in an air-tight bottle nearly filled with water, and the other dips into the funnel. A straight open tube is also inserted in the bottle, the lower end of which is about half an inch or an inch above the end of the syphon. It is obvious that the water will run from the syphon no longer than till the water in the funnel is level with the end of the straight tube. The same effect may be produced by using an inverted bottle and tube, as figured in page 933.

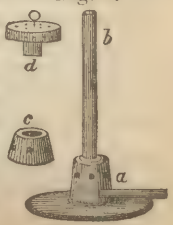
Separation of Liquids. Liquids which have no chemical affinity, and differ in specific gravity, may be separated by allowing them to remain at rest in the separating funnel represented in the annexed figure, and then drawing off the heavier fluid. Another very convenient method of separating fluids is by means of the *separatory* figured in the woodcut in the margin. The last drops of the heavier fluid may be drawn off by means of this instrument.

Application of Heat. The most efficient and economical means of obtaining heat is a subject of great importance to the pharmaceutist, on account of the variety of processes in which it is required.



With the small *furnaces*, which are now made of fire-clay, of various patterns and sizes, almost all the operations of the laboratory which require heat can be performed. The fuel used is charcoal, although anthracite will burn in those of a larger size, and is to be preferred where a uniform heat is necessary for several hours. The apothecary should be provided with a complete set of these useful utensils, including one with a dome for a reverberatory furnace. By adding a pipe several feet in length to this, and urging the fire with a pair of double bellows, the heat may be raised to that of an air furnace. A small pipe of sheet iron with a cone at the lower end, as in the figure, to fit on the furnace, will be found an excellent means of obtaining an intense heat in those of the smallest size. For operations on a smaller scale, a convenient means of obtaining heat is by alcohol lamps. Alcohol burns without smoke or smell, and is on every account, except its price, preferable to oil as a fuel. The figures beneath represent the usual forms of *spirit lamps*. The larger one will be found very useful in heating spatulas for spreading plasters.





Gas burners afford a yet more eligible and economical means of applying heat than alcohol lamps. When coal gas is mixed with a due proportion of atmospheric air before ignition, it burns with a bluish flame, and produces but little if any smoke. The gas burner consists of a cylinder of sheet or tinned iron from 2 to 4 inches in diameter, and 6 or 8 inches long, open at the inferior end, while the upper end, which is slightly flared, is covered with a piece of number 40 or 50 brass wire-gauze, fastened on with wire. This burner is supported vertically over an ordinary gas jet in any convenient position, and the gas, on being allowed to issue into it, rises from its superior levity, mixes with the air, and is ignited by means of a taper above the gauze. The heat can be managed by regulating the flow of gas, and by using burners of different sizes. The left of the two figures in the margin exhibits this arrangement. That on the right, in which a tube conveying gas (*a*) enters the cylinder horizontally while the air passes in at *b* below, is an arrangement suggested by Dr. Bridges, and may be adapted to the common bat-wing or fish-tail gas burner.

Bunsen's gas burner, with Griffin's modifications, is a very convenient instrument, now much used. The simple burner consists of a tube (*b*, fig. 1), screwed into the top of a metallic stand (*a*, fig. 1), containing a small chamber, which is provided with four lateral openings for the admission of air. Beneath these openings a gas tube enters the chamber, ending in a small jet tube in its axis, so that the gas is made to mix thoroughly with the atmospheric air entering through the orifices, before it reaches the mouth of the burner, thus ensuring a more thorough combustion and a stronger heat. One of the modifications of the simple burner is a cap of brass, shaped like a truncated cone (*c*, fig. 1), with four lateral perforations, which fits around the chamber (*a*), and rotates about it, so as to close

Fig. 1.

or open its orifices at will, and thus regulate the flame. Another modification is a cylindrical cap of brass, to be fitted to the top of the tube, perforated with numerous small holes at its circumference, and having at the top either a few small holes (*d*, fig. 1), or one large opening in the centre, furnished with a sliding valve by which it may be opened or closed at pleasure (*b*, fig. 2). The burner is represented in action by fig. 2; at *b*, with the flame issuing from the central opening at the top, and at *a* with this opening closed, and the burning gas escaping at the lateral orifices; the former being adapted to produce a concentrated heat, as for igniting crucibles, the latter for a more diffused heat, as in

Fig. 2.

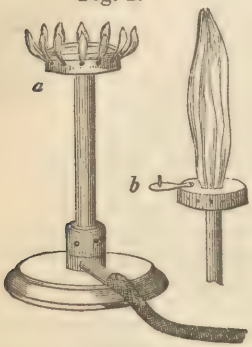


Fig. 3.

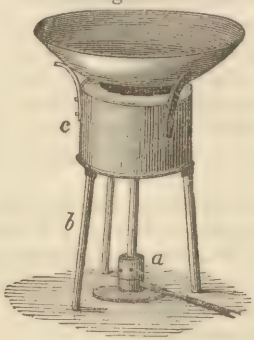

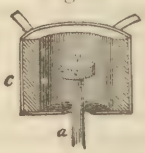

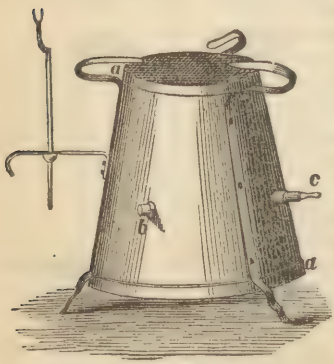

Fig. 4.

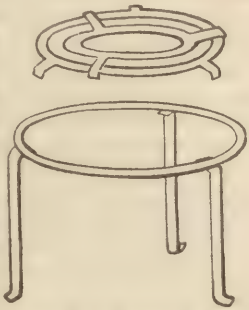
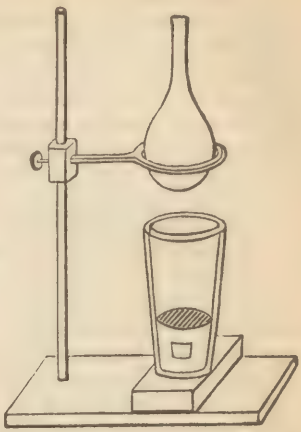
evaporation. Fig. 3 represents the burner surrounded by a sheet-iron cylinder, supported on three legs, and provided at top with three short arms, for the support of the vessel to be heated. Within this is a cylinder of fire-clay, which serves to confine the heat. The whole forms a small furnace, a section of which is exhibited in fig. 4, in which the position of the burner is shown within the cylinder. (See *Am. Journ. of Pharm.*, Jan. 1862, p. 46.)*



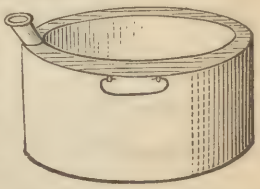
Warren's laboratory safety lamp is another instrument meriting a brief notice. It is intended to protect from danger of fire, in distilling ether and other inflammable liquids. It consists of a truncated cone of sheet iron, 6 inches in diameter at bottom by 4 at top, and 5·5 inches high, with a top and bottom of No. 50 brass wire-gauze, held in place by movable brass rings, as at *a a*. An opening (*b*) in the side, which may be closed with a cork, serves for applying a match. Another opening (*c*) admits the entrance of a piece of gas pipe, which then forms a horizontal ring in the centre of the instrument, 3·5 inches below the upper gauze. This is provided on the upper surface with small holes for the escape of gas. When used as a safety lamp, the gas is to be lighted within, and the flame will be confined by the gauze; when for ordinary purposes, the gas may be lighted above the upper gauze. The air for combustion is supplied through the lower gauze. The notched rod at the side is for the support of retorts, tubes, &c. (See *Am. Journ. of Pharm.*, May, 1862, p. 218.)



For supporting the substance to be heated, iron tripods, of various heights and sizes, must be provided. These should be furnished with sets of concentric rings, as in the figure, for vessels of different sizes. A very convenient support is the stand and ring figured in the wood-cut, which will answer for

* We are informed that these furnaces have been made for sale by Messrs. Bullock & Crenshaw, Philadelphia.

a spirit lamp, or for a small furnace made from a black lead crucible, as in the figure.



The temperature required for fusion in pharmaceutic processes seldom exceeds a red heat; and the vessels used are *crucibles* of silver, platinum, porcelain, Wedgwood ware, black lead, and fire-clay (Hessian crucibles). Silver is used for the fusion of potassa, porcelain for nitrate of silver, and black lead and Hessian crucibles for the metals, glass of antimony, sulphuret of potassium, and the ordinary operations which require a great heat. They are severally liable to objections; silver fuses too readily; platinum is very costly; porcelain and Wedgwood ware do not bear sudden changes of temperature; black lead, which bears these changes, is destroyed by saline substances, and burns in a current of air; and the Hessian crucibles are so porous as to absorb and waste much of the fused substance. The crucible should be covered with a lid or an inverted crucible, and should be supported at a little distance from the bottom of the grate, and surrounded and covered with ignited coals.

Liquefaction is performed in open earthen, copper, or iron vessels, and care must be taken not to raise the heat so as to char or inflame the substance.

A *sand-bath* is an indispensable part of the pharmaceutic apparatus. It is usually an iron pot, or a shallow vessel of sheet iron, capable of holding sand to the depth of four or six inches. It serves to regulate the action of the heat on vessels which do not bear a rapid change of temperature. It is sometimes heated to a red heat, as in preparing the mineral acids, though more frequently used for the evaporation of saline solutions and vegetable juices.

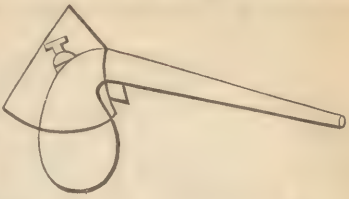
Evaporation is one of the most important operations of the pharmaceutical laboratory, and on its proper management depends the value of a large number of preparations. The readiness with which organic matter is modified by direct heat, has caused the invention of various means and apparatus to effect evaporation under the most favourable circumstances, as the *water-bath, steam-bath, solution bath, vacuum pans,* &c.

The *water-bath* is to be used in all cases where a heat above that of boiling water would be injurious. A convenient one consists of two copper vessels, the upper one of which is well tinned. It is still more convenient to have the water-bath constructed as a hollow vessel, with one opening at the top for the escape of steam and for the introduction of the water, as in the figure. By inserting a cork in the aperture, the contents of the inner vessel may be poured out, as from a dish, without spilling the water. It may be made of tinned iron, or preferably of tinned copper. Where a temperature above that of boiling water, and not exceeding 228°, is required, the water-bath may be filled with glycerin, or a saturated solution of common salt, sulphate of soda, or chloride of calcium, the last-mentioned salt permitting a heat as high as 240° when desired.

Steam-baths are by far the most useful and easily regulated of the arrangements for indirect heating. When steam heat is applied in a double-sided vessel like the water-bath, this is called a steam jacket, and must have two openings, one for the ingress of the steam, the other for the exit of the air, and for drawing

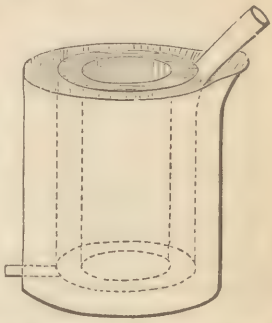
off the condensed water. When the steam jacket is strongly made, a heat of 300° may be readily commanded. A more economical and easily applied arrangement consists in placing a coil of tube in the vessel containing the liquid to be evaporated, and causing a strong current of steam to circulate through it. For further remarks on apparatus for evaporation, including the vacuum pan, see *Extracts*.

The apothecary should be provided with a set of evaporating vessels, of porcelain, glazed iron, tinned iron, and copper. For metallic solutions vessels of Berlin porcelain are the most useful. In most cases of surface evaporation, where the product is uncrystallizable, the process should be hastened by stirring.

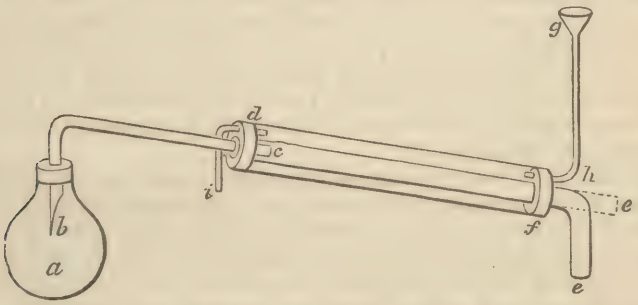


Distillation consists in vaporizing a liquid in one vessel, and conducting the vapour into another vessel, where it is condensed and collected. The process is used for separating a liquid from solid substances which it may hold in solution, or with which it may be mixed; for separating a more volatile liquid, as ether and alcohol, from one less so; for impregnating a liquid with the volatile principles of plants to the exclusion of other principles, as in the preparation of aromatic spirits and waters; and for separating, by means of aqueous vapour, the essential oils and volatile proximate principles of the vegetable kingdom. When, in the last two operations, the distillation is repeated with the same liquid and a fresh quantity of the plant, the operation is called *cohobation*. The process for separating one liquid from another is termed *rectification*. Distillation is also used for obtaining the volatile products which result from the decomposition by heat of substances of animal or vegetable origin. The oils which are obtained in this manner are called *empyreumatic oils*. Sometimes the result is an acid, as the succinic acid, and sometimes a volatile alkali, as in the destructive distillation of animal substances. Alcohol is very often employed as a mere agent in pharmaceutic processes, and, after it has performed its office in the process, may either be thrown away with the refuse liquids, or separated and preserved by distillation. The low price of alcohol in this country had until recently rendered the former proceeding the more expedient of the two; but alcohol is now so much enhanced in price that the apothecary will generally find his account in saving it by distillation.

The *common still and worm*, the vessels in general use for *distillation*, are too well known to need description. A convenient still or alembic for small operations, which may be heated by a spirit lamp, is figured in the wood-cut. The top of the head is kept filled with cold water; and all escape of vapour is prevented by having an inner ledge to the still, and filling the space in which the head fits with water. The condensation of all the vapour is secured by adapting a worm, or a long tube, to the apparatus. The boiler of this still may hold one or two gallons, and it will be found a very useful means of recovering the alcohol, in making alcoholic extracts. It may easily be converted into a water-bath, by fitting on the top of the boiler a vessel of convenient form. These stills are easily adapted to the common cylindrical anthracite stoves, used for heating, by means of a sheet-iron collar, through which the boiler of the still is made to pass, and on which it is supported.

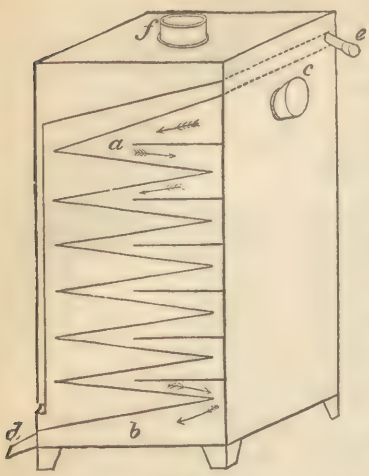


When the common glass retort and receiver are used for the distillation of liquids, care should be taken not to apply the luting until the atmospheric air is expelled, unless the receiver has a tubulure for its escape. The chief objects to be aimed at are to keep the body of the retort hot, and the neck and receiver cool. A hood of pasteboard or tin, as represented in the figure, will much facilitate the former; and the latter will be gained by keeping the neck and receiver wrapped in wet cloths, on which a stream of cold water is kept running. This may be conveniently done by means of a syphon, made by dipping one end of a strip of cotton or woollen cloth in a vessel of water, and allowing the other end to hang down upon cloths bound loosely around the



receiver and the neck of the retort. The apparatus figured in the margin is one of the best for the condensation of ethereal vapour, as in regaining the ether in the process for making ethereal extracts. It consists of a close, hollow, cylindrical tin vessel, having a large neck above for the insertion of the neck of a retort or a tube; and a small tube below for the escape of the condensed ether. This vessel sits in a large one open at top, which is kept filled with cold water, constantly renewed by a tube descending to the bottom.

Liebig's distillatory apparatus, commonly so called, but originally invented, we believe, by the elder Weitzel, of Stockholm, is very convenient for performing the process of distillation on a small scale. Its peculiarity consists mainly in the *refrigeratory* for condensing the vapour. Below is a figure of the instrument, which, with the description, is copied from the last edition of the Edinburgh Pharmacopœia.



"In all operations, except where inorganic acids are to be distilled, it is greatly preferable to use a globular matrass (*a*), to which is fitted with a cork a tube (*bc*), cut obliquely at its lower end (*b*), curved above at a somewhat acute angle, and

fitted at the other end to a refrigeratory. This refrigeratory consists of a long narrow cylinder (*df*) slightly inclined to the horizon, and of a tube (*ce*) which passes along the centre of the cylinder, and is fixed at each end, so that the space between them is air-tight; and by means of a funnel (*gh*) entering at the lower end of this interspace, and an exit tube (*di*) from its upper extremity, a stream of cold water may be kept constantly running, by which refrigeration, and the condensation of vapours within the inner tube, are far more effectually accomplished than by any other mode that has hitherto been devised." The object of the oblique ending of the tube at *b*, is to prevent any of the fluid which may be driven against it, during the ebullition, from passing along the tube. The inner tube of the refrigeratory should be made of glass or block-tin, the outer may consist of glass, brass, copper, or common tinned iron. The end *e* of the central tube is either straight, or curved downward so that it may be inserted into a bottle, when the liquid distilled is very volatile. By connecting the funnel with a cistern by means of a syphon, and allowing the water to flow out from the bent tube (*di*) into a bucket or sink, the distillation may be allowed to go on for a long time without supervision. Dr. Christison states that a refrigeratory, with the outer tube a foot long, and an inch and a quarter in diameter, will be sufficient to condense the whole vapour from a matrass, holding two pints of alcohol briskly boiling.

Warner's condenser. This is a convenient instrument in the distillation of

alcoholic liquids, invented by Mr. W. R. Warner, and figured in the *American Journal of Pharmacy* for January, 1861 (p. 15). It consists of an oblong rectangular box of tinned iron, with a broad opening (*f*) at top, for the admission of the refrigerating liquid, and a smaller one (*e*) near the top for its escape. A diaphragm is placed in the vessel near the top obliquely across, so that one of the four angles is lowest. From this angle, communicating with the small compartment above, a tube proceeds downward to near the bottom of the vessel; and a little below its orifice another diaphragm is placed, but not completely across like the first. Connected with the edge of the lower diaphragm is a series of partial ones, oblique like the others, proceeding upward, and so connected as to divide the vessel into two equal parts, leaving a small space between the edges of the partitions on each side and the sides of the vessel, and a space also between the uppermost of the partial partitions and the complete diaphragm near the top. Into this space a tube (*e*) is inserted near the top of the instrument. The vapour admitted through a large opening (*c*) in the upper part of one side of the vessel, enters into one of the compartments, while cold water poured in through the opening at top fills the other compartment, and escapes through the tube (*e*) near the summit. The vapour being compelled, by partial septa, to follow the course of the oblique partitions, along a circuitous route (*ab*), in which it is brought into contact with a large extent of refrigerated surface, is condensed, and passes out at the spout near the bottom.*

When certain liquids are boiled in glass vessels, sudden jars or succussions are apt to occur, which are often inconvenient, and sometimes interrupt the process. These may be obviated by giving a metallic coating to the lower portion of the interior surface of the vessel. Mr. Redwood recommends for this purpose the process of Drayton. He introduces into the flask or retort as much ammoniacal solution of silver as may cover the part to be coated, precipitates the silver by the addition of essential oils, and afterwards thoroughly cleanses the vessel by boiling in it successive portions of alcohol, until the silver becomes perfectly bright, and all smell of the oil is removed. A coating of platinum may also be obtained, though less perfect, by precipitating a solution of the bichloride of that metal by formic acid, and afterwards boiling. (See *Am. Journ. of Pharm.*, xx. 333.) These succussions are moderated and sometimes prevented by putting in the retort a number of small angular fragments of glass or quartz crystal. Ac-

* Two new stills for pharmaceutical purposes, one by Prof. Wm. Procter, Jr., the other by Mr. Thos. S. Wiegand, of Philadelphia, are described and figured in the *Proceedings of the American Pharmaceutical Association*, A. D. 1863, pp. 207 and 210, both of which merit the attention of pharmaceutists. (*Note to the twelfth edition.*)

When mixed liquids to be separated by distillation have closely approximating boiling points, it is often difficult to get them pure, or so nearly pure as to have a constant temperature of ebullition; the less volatile being constantly disposed to rise with those which are more so, and thus contaminate the product. Mr. C. W. Warren has contrived an apparatus in which the evil is in a considerable degree obviated. This he accomplishes by causing the vapours from the distilling vessel to pass, by means of a worm, through a bath, kept at a heat corresponding with the boiling point of that one of the mixed liquids which has the lowest. When the mingled vapours pass through the bath, those which belong to the less volatile bodies condense into a liquid which falls back towards the still; while the most volatile passes on, and is condensed by cold water or ice in a receiver. The apparatus, as well as the principles on which it operates, is explained by Mr. Warren in the *Chemical News* (Aug. and Sept. 1865, pp. 85, 97, 110), where it is also figured. See also *Am. Journ of Pharm.*, 1865, p. 449. (*Note to the thirteenth edition.*)

cording to Dr. G. C. Wittstein, all that is necessary to prevent them is to have some conductor which may convey the heat from the bottom of the fluid to the surface. A glass rod will generally answer the purpose, but for liquids of a high boiling point, as sulphuric acid, a platinum wire of the thickness of a knitting-needle is preferable. P. Pellogio has proposed a plan by which these shocks may be entirely prevented, even in the instance of sulphuric acid. It consists in the insertion of a glass tube, as wide as possible, through the tubulure nearly to the bottom of the retort, with the upper end bent almost to a right angle, and drawn out to nearly capillary dimensions, so as to establish a communication between the cavity of the retort and the outer air. (*Chem. News*, April 3, 1866, p. 165.)

When the object of distillation is to preserve the residuum, and this is liable to injury from heat, as is the case with vegetable extracts, the operation is best performed in vacuo. For this purpose the still and recipient are made so as to form an air-tight apparatus, and the latter is furnished with a stop-cock, which is kept open until the whole of the atmospheric air is expelled by the vapour. It is then closed, and a vacuum formed and maintained in the recipient by surrounding it with cold water. The distillation is carried on in this manner at a much lower temperature than under ordinary circumstances; and the heat may be applied by a water or steam bath, with greater certainty of obtaining an uninjured product. For a more extended account of vacuum apparatus, see *Extracts*.

Sublimation. The vapours of some volatile solids have the property of condensing into the solid form, either in mass, or in a state of minute division. The operation in which this occurs is called *sublimation*. When the product is compact it is called a *sublimate*, when slightly cohering it is called *flowers*. The operation is generally performed in a sand-bath; and the apparatus consists of two vessels fitting each other, one being inverted over the other. The shape, size, material, and depth of the vessel, and the degree of heat to be applied, are regulated by the nature of the substance operated on. For the details of this process, see the articles *Corrosive Sublimate*, *Camphor*, and *Benzoic Acid*.*

* *Micro-sublimation.* This name has been given to a process, first suggested by Dr. Helwig, of Mayence, in 1864, and afterwards investigated by Prof. Wm. A. Guy, of King's College, and Mr. H. J. Waddington, of London, which consists in the joint application of a subliming heat and of the microscope to the examination of volatilizable substances. The objects gained by the process are the determination of the volatility of bodies, the precise temperature at which they sublime, and the forms they assume when they condense from the state of vapour, and thus the ability to identify the several substances examined, even though existing in very small proportions, and mixed with various other bodies. The adaptability of the process to the detection of poisons is one of its greatest merits; and in this light it was originally mainly treated by Helwig; but it is susceptible of a wide application to the interests of science in general. Perhaps the most important part of the process is the proper regulation of the heat, so that it shall act with entire uniformity on the object, and, as to its degree, shall be perfectly at the command of the operator. The want of these advantages has led to great mistakes in previous investigations, both as to the volatility of certain substances, and the true subliming points of many known to be capable of sublimation. The following is the description of Mr. Waddington's apparatus for the application of heat. It consists of a spirit lamp, a piece of thin iron plate, and a few glass rings. There should be a very slight concavity in the upper surface of the plate, so that when a glass slip three inches long is laid upon it, the centre shall be about an eighth or sixth of an inch below the surface of the glass. This is to prevent actual contact between the plate and the glass holding the substance under examination. The plate has three straight parallel lines drawn across it, one through the centre, the others an inch and a half distant on either side. The glass rings are for the support of a glass plate for the reception of the sublimate. The object is placed on a slip of glass, which is laid on the iron plate, and the recipient placed over it on a ring. The glass which receives the sublimate should not be very thin, as it changes temperature too rapidly. The slide of a microscope is a proper recipient. The flame of the lamp should not be immediately beneath the object. As the heat of the iron plate varies somewhat, the desired degree may sometimes be obtained by moving the supporting slip from side to side. The object should always be aimed at of having the receiving glass but a few degrees lower in temperature than that which holds the object. The quantity operated on may be very small; and generally the smaller the quantity the better the result. A convenient quantity is $\frac{1}{20}$ of a grain; but perfectly

Lutes. The most precious material for the chemist is glass, the transparency, insolubility, and hardness of which fit it for almost every purpose. It is often necessary to strengthen it by means of lutes, which will bear a heat at which glass would soften; and the application of lutes for this purpose, and for securing the junctures of tubes and vessels, is an important part of the pharmaceutic art. Those lutes which are required for coating vessels exposed to a great heat are made of Stourbridge clay. The clay is made into a paste with water, mixed with chopped straw or cut hemp, and successive coats applied as they become dry. Dr. Hare recommends the fine wool-like turnings of iron for this purpose, instead of chopped straw. Earthenware vessels may be rendered impervious to air or vapours by brushing over them a thin paste, made of slaked lime, and a solution of borax containing an ounce to the half pint. This is allowed to dry, and the vessel is then coated with slaked lime and linseed oil, beaten till the mixture becomes plastic. Earthenware retorts, thus coated, may be safely used more than once, the coating being renewed every time.

Fat lute is applied to the joinings of apparatus to prevent the escape of corrosive vapours. It is made like glaziers' putty, pipe-clay being substituted for whiting. It will bear a considerable heat, and great care must be taken that the part where it is applied is perfectly dry. If it be exposed to heat, slips of moistened bladder must be wrapped around it, and secured with twine.

Roman cement and plaster of Paris may be applied in the same manner as fire-clay. When used for securing the joinings of apparatus, a coating of oil or wax will render them air-tight.

A very useful lute is formed by beating the white of an egg thoroughly with an equal quantity of water, and mixing it with some slaked lime in the state of fine powder so as to form a thin paste. This must be spread immediately on strips of muslin, and applied to the cracks or joinings intended to be luted. It soon hardens, adheres strongly, and will bear a heat approaching to redness without injury. A leak in this lute is readily stopped by the application of a fresh portion. Solution of glue, or any liquid albuminous matter, may be used in the place of the white of eggs.

The following recipe is given by M. Knaff for a *strong liquid glue*, which is said not to gelatinize, to keep well, and to be very convenient for pasting. Take 3 parts of good glue in little fragments, cover it with 8 parts of water, and allow it to stand for some hours; then add half a part of muriatic acid and three-fourths of a part of sulphate of zinc, and expose the whole for ten or

characteristic sublimates may be obtained from as little as $\frac{1}{1000}$ or $\frac{1}{1500}$ of a grain. By this process many organic substances have been proved to be sublimable not formerly thought to be so. This is the case with many of the vegetable alkaloids, and many proximate principles not alkaline. All the sublimates unchanged by heat should possess the crystalline form of the original substances; and Mr. Waddington never considers a result satisfactory unless this end is obtained. In reference to the determination of the temperature of fusion and sublimation, Prof. Guy attaches a thermometer to the apparatus. The bulb of this he fixes in the centre of a copper plate, and attaches the stem to a retort stand to support it. On the copper plate a minute portion, say $\frac{1}{100}$ of a grain, of the body to be examined, is placed, on a small piece of glass, somewhere between the centre and circumference, and around this a glass ring, on which is placed the disk for receiving the sublimate. The heat is then applied to the under surface of the copper plate, at a point equidistant from the object and the bulb of the thermometer. (See a figure by Prof. Guy in the *Pharm. Journ. and Trans.*, Feb. 1868, p. 372.) It is a common statement that certain bodies are partly volatilized and partly decomposed by heat. But the probability is that there is a subliming point at which no decomposition takes place; and the contrary has been supposed because slight differences of temperature have not been observed in the ordinary methods. There are many directions and cautions more or less requisite for a successful application of this process, for which we have no space, and must content ourselves with referring to the original essays. Throughout the present edition, we have noticed here and there the results obtained in reference to individual objects, always quoting the authority. (See papers by Prof. Guy in the *Pharmaceutical Journal and Transactions*, June, 1867, p. 718; July, Aug., Sept., and Oct., 1867, pp. 10, 58, 106, and 195; and Feb. 1868, p. 370; also by Mr. H. Waddington, *Ibid.*, March, 1868 p. 409. See also *Am. Journ. of Pharm.*, Sept. 1867, p. 432; and *B. & F. Medico-chir Rev.*, Oct. 1868.)—*Note to the thirteenth edition.*

twelve hours to a heat between 178° and 189° F. (See *Am. Journ. of Pharm*, July, 1868, p. 330.)

An excellent cement for surfaces of iron consists of one part of sulphur, two of sal ammoniac, and eighty of iron filings, mixed together and slightly moistened. It is rammed or caulked into the joints, and solidifies perfectly in time

White lead ground in oil is an excellent cement for broken glass. Spread upon linen, it forms a good coating for a cracked surface, but dries slowly. Strips of bladder macerated in water adhere well to glass, and are very useful.

A mixture of whiting and paste or gum-water, spread upon strips of paper, forms an excellent luting for joinings not exposed to acrid vapours or great heat.

A useful lute is formed by spreading a solution of glue on strips of cloth, and coating them, after they are applied, with drying oil.

Linseed meal, beaten into a uniform mass with water, milk, lime-water, rye paste, or thin glue, and applied in thick masses, adheres well, and when dry will resist most vapours.

Cap cement is made of six parts of rosin, one part of yellow wax, and one of Venetian red. It is a very useful cement for fastening metals or wood to glass, and for rendering joints impervious to water. *Soft cement* is used for the same purposes, and is made of yellow wax, melted with half its weight of turpentine, and coloured with a little Venetian red. It is very useful for rendering the stoppers of bottles perfectly air-tight.

The *Armenian* or *diamond cement*, used for cementing glass, precious stones, &c., and highly esteemed by the jewellers of Turkey, is made in the following manner in the East. "Dissolve 5 or 6 pieces of mastic, each of the size of a large pea, in as much alcohol as will render it liquid. In another vessel, dissolve in French brandy or good rum as much isinglass, previously softened by water, as will make a two-ounce phial full of very strong glue, to which small pieces of galbanum or ammoniacum must be added, and rubbed with it till dissolved. Then mix the whole with sufficient heat, and keep the glue in a phial closely stopped. When used, the phial containing it is to be put into boiling water." (See *Am. Journ. of Pharm.*, Jan. 1866, p. 57.)

A cement of which *gutta-percha* forms a part has been very highly recommended by Edmund Davy. It is made by melting together, in an iron pan, two parts of common pitch and one of gutta-percha, stirring them well together until thoroughly incorporated, and then pouring the liquid into cold water. When cold it is black, solid, and elastic; but it softens with heat, and at 100° is a thin fluid. It may be used as a soft paste, or in the liquid state, and answers an excellent purpose in cementing metal, glass, porcelain, ivory, &c. It may be used even for glazing windows. (See *Am. Journ. of Pharm.*, xxix. 457.)

French cement is made by gradually adding finely powdered slaked lime to caoutchouc, perfectly melted over a fire in a covered iron pot, stirring constantly, until the mixture is so thick that, removed from the fire, well beaten in a mortar, and moulded in the hands, it shall have the consistence of putty. It answers well for cementing glass. (*Ibid.*, July, 1864, p. 374.)

Caoutchouc, dissolved in heated copal varnish, is said to make a good waterproof glue, for cementing wood and leather.

Casein, dissolved in a cold saturated solution of borax or of silicate of soda, is recommended by Dr. Wagner as a cement, answering the purpose of strong glue in many instances.

A new cement, having excellent properties, is described by M. Sorel. It is a hydrated basic oxychloride of magnesium, and is prepared by mixing magnesia with a solution of chloride of magnesium. The cement is harder in proportion to the greater density of the solution. In most cases M. Sorel employs a solution of 20° to 30° of the areometer of Baumé. In preparing the cement various other metallic chlorides may be substituted, in whole or in part, for the chloride of magnesium. It is very white, and becomes very hard, and may be moulded like plaster. Objects may be made with it having the hardness and colour of marble. (*Journ. de Pharm. et de Chim.*, Mai, 1868, p. 328.)

Chemical Operations. Some of the chemical processes, conducted by the apothecary, have been explained in the former part of this Introduction. It remains to notice others in constant or frequent use.

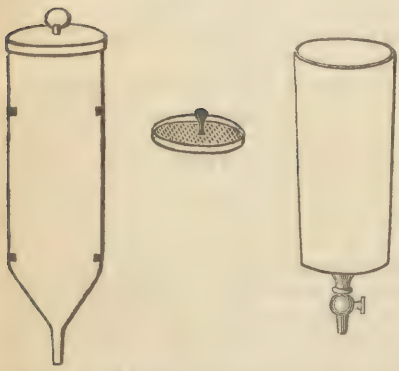
Solution. The act of solution, in which solid substances assume the fluid state through the agency of liquids, is one of the most important operations of practical pharmacy. The process has received a variety of names, according to the mode of applying the menstruum and the degree of heat employed; as *maceration, infusion, digestion, decoction, displacement* or *percolation,* and *circulatory displacement.**

Two classes of substances are the subjects of solution; those which dissolve entirely in the menstruum, as salts, gum, &c., and those which consist of soluble and insoluble matter, as roots, leaves, barks, &c. The former yield *simple solutions;* the latter *infusions, decoctions, tinctures, wines,* &c. Solution is sometimes accompanied by chemical reaction, as when metals are dissolved in acid liquids. Mechanical division facilitates solution by increasing the extent of surface. Heat as a general rule favours solubility. All aqueous solutions of solid bodies are denser than water. A solution is said to be saturated when the dissolved substance ceases to be taken up at common temperatures. A saturated solution of one salt will dissolve other salts, a fact taken advantage of in purifying nitre, and other saline bodies in powder, by percolating them with their own saturated solutions. Rapid solution, when unaccompanied by chemical reaction, causes a reduction of temperature; hence, in such cases, where dense solutions are required, heat should be employed to counteract that effect. In dissolving a substance wholly soluble in the amount of liquid used, a convenient method is to powder it in a mortar, add the liquid in portions, and decant until the whole is dissolved. Capsules and flasks are the most suitable vessels for performing solution when heat is necessary. If the solid softens before dissolving, as in the case of the extracts, a capsule should be used, with constant stirring. When effervescence occurs, a flask should be used inclined to one side to avoid loss; or, if the capsule be employed, an inverted funnel should be placed over it. When the quantity of a substance is large, and time permits, the process called *circulatory displacement* is preferable, especially in making saline solutions. This is performed by suspending the salt, enclosed in a piece of gauze or other porous tissue, near the surface of the liquid. The solution proceeds rapidly; as the liquid in contact with the salt, by becoming saturated and heavier, descends to give place to less saturated portions, so as to cause a kind of circulation of the solvent. This process is applied to the arts, and has been suggested in making infusions and tinctures.

Infusion is the subjecting of a substance containing soluble principles to the action of a menstruum, which is usually water. Hot infusions are made by pouring boiling water on the substance, and allowing it to remain in a covered vessel till cold. Cold infusions are made with cold water, and require several hours to attain their full strength. *Maceration* is the term employed to denote the action of liquids upon medicines, when allowed to remain upon them for some time, at a heat from 60° to 90°. *Digestion* is the name given to the same operation, when conducted at a temperature between 90° and 100°. This process is sometimes effected at higher temperatures; but the heat is uniform during the operation, and always below the boiling point of the liquid. It is commonly performed in glass bottles or flasks, and a common fire or stove heat, or the water-bath, is employed. When digestion is performed with alcohol and ether at temperatures near their boiling points, the vessel should be connected with a refrigerated worm, or other condenser, to save the vaporized portion. Soubeiran places the worm above the digesting vessel, so that the condensed liquid runs back at once into the vessel.

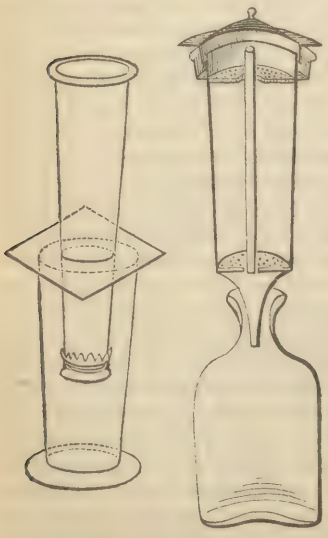
* The attention of physicians and apothecaries is called to *Storer's Dictionary of Solubilities,* recently published in Cambridge, Mass., in which useful information on the solubility of different substances may often be found, which might not be readily obtained elsewhere. (*Note to the twelfth edition.*)

Decoction, or boiling, is much employed in extracting the virtues of plants; but it is often disadvantageous, as most of the proximate principles of vegetables are altered by it, especially when long continued. When it is practised, the ebullition should generally be continued for a few minutes only, and the liquid be allowed to cool slowly in a close vessel. For further remarks on infusions and decoctions, see the preliminary notices to these classes of preparations.



Lixiviation is a process used to separate a *soluble* from a porous *insoluble* body. It consists in placing the substance to be lixiviated in a vessel, the bottom of which is covered with straw, sand, &c., pouring water upon it, allowing the water to remain until saturated, and then drawing it off through an opening at the bottom of the vessel. It is found that, if fresh water is poured on without disturbing the mixture in the vessel, it does not mix with the liquid already there, but percolates the solid particles, driving the saturated liquid before it; so that, for example in lixiviating wood ashes, if a gallon of water has been poured on the ashes, and allowed to become saturated with the alkali, we shall obtain, by this mode of proceeding, a gallon of strong ley, and immediately thereafter the water will become almost tasteless. This fact has been applied to the service of the pharmaceutist, and has led to some valuable improvements in the mode of extracting the medicinal qualities of plants.

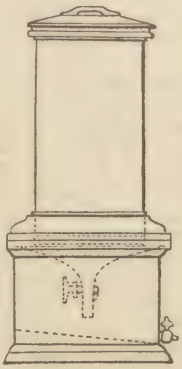
Percolation. Filtration by Displacement. This is the process of lixiviation, applied to pharmaceutical processes, under certain conditions and with certain objects which give it a somewhat distinctive character. It was first introduced into notice by the Messrs. Boullay, of Paris, in the year 1833, and, though received at first with some hesitation, has now come into almost universal adoption, and is officinally recognised as an important agency both in the U. S. and British Pharmacopœias. The principle of the process is, that a permeable powder, consisting partly of soluble and partly of insoluble substances, when submitted, in a cylindrical or conical instrument, open at top and partially closed by a porous material at bottom, to the action of a menstruum poured upon it, yields its soluble parts to the liquid, which, in its descent by its own gravity or by pressure from the liquid above, becomes more or less saturated, and in this state escapes beneath, without mingling in its passage through the powder, or but in a slight degree, with the liquid pressing upon it from above. If the menstruum be supposed to be in layers in the powder, the lower layers are pressed downwards or displaced by the upper with little admixture, so that they severally escape from the instrument with the degree of concentration acquired in their passage; and each successive layer is less and less impregnated, until the powder is at length exhausted, and the liquid last added passes in the state in which it enters. Now what is true of one liquid is true of different liquids; and if a particular liquid be first added, and then followed by a second, the two do not mingle, and the latter takes from the former little or nothing of what it may have dissolved. Thus, if alcohol or ether be first introduced, and then followed by water, the alcoholic or ethereal solution formed may all be displaced by the water, without being to any considerable extent diluted with it. The idea was at one time entertained, that there was absolutely no intermixture or next to none; but experience has shown that this was not exactly true, and that there is in fact a slight mixture of the successive and contiguous layers.



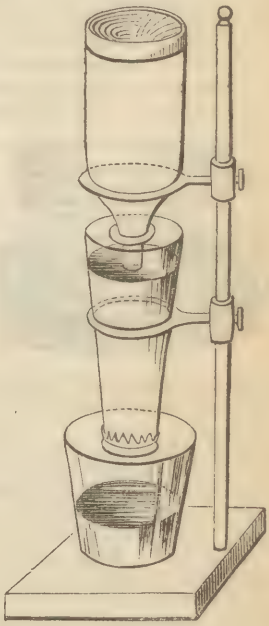
A little reflection will show, what abundant trial has proved, that this method has advantages in various ways, over that of simple mixture of the solid and liquid, however this may be aided by other agencies, as by agitation, heat, and expression. In the first place, the particles of the menstruum are brought more thoroughly into contact with those to be acted on, and each successive layer of the liquid comes into contact with the solid with a higher solvent power than that which it has displaced; so that the powder is both more rapidly and more thoroughly exhausted. In the second place, as the liquid which first passes is saturated or nearly so before it escapes, highly concentrated solutions may be obtained with great facility; and, each successive portion being less and less saturated, it is possible in this way to separate the stronger from the feebler

portions, which is sometimes an object of great practical importance. Thirdly, the last particle of dissolved matter may be obtained by displacing the liquid by another menstruum or an additional portion of the same, and great waste thus avoided; and though the same object may be accomplished to a great extent by expression, the method of displacement is both more thorough and convenient. Fourthly, by the employment of a cheaper menstruum as the displacing agent, considerable loss may be saved, in obtaining solutions in which the menstruum is very costly. A single example will serve to show the value of this process. The Messrs. Boullay, by subjecting four ounces of bruised cinchona to percolation with half a pint of water, and then adding four half-pints in succession, obtained the following results.

1st	half-pint	yielded	3 drs. 48 grs.	dry extract.
2d	do.	"	1 dr. 5 grs.	do.
3d	do.	"	15 grs.	do.
4th	do.	"	9 grs.	do.
5th	do.	"	7 grs.	do.



The figure in the margin represents *Boullay's filter*, or *percolator*. It consists of a long tin vessel, nearly cylindrical, but narrower at the lower end, which has a funnel-shaped termination, for the purpose of being inserted in the neck of a bottle. A metallic plate, or diaphragm, pierced with holes, like a colander, and having a handle in the centre, fits accurately in the lower part of the cylinder; and upon this is to be placed, when the instrument is used, a thin layer of carded cotton, tow, or a piece of cotton flannel. Another similarly pierced plate is to be provided, to place upon the top of the powder after it has been introduced into the percolator. A stop-cock at the lower end of the instrument, as represented in the second figure, will be convenient for regulating the discharge of the liquid.



Cylinders 14 inches long by 2½ in width at the base, 14 inches by 4, and 17 by 6, are convenient sizes for ordinary use. Queensware percolators are now to be procured from the druggists, and are useful for acid or astringent solutions. In a large proportion of the cases of percolation, small vessels only are required. The common glass cones used as lamp glasses, figured in the margin, when inverted, with a piece of close canvas or flannel tied over the smaller end, form convenient percolators; and their transparency enables the operator to assure himself that the powder is properly stratified before adding the menstruum. A tin percolator, formed with a double rim, into which the rim of the lid is inserted (the interstice being filled with water so as to make an air-tight juncture), and furnished with an open vertical tube, extending from the top through the diaphragm below, is employed when volatile liquids, as ether, alcohol, and spirit of ammonia, are used as menstrua. It is figured in the margin. When it is wished to operate upon a very fine powder, it may be found advisable to increase the height of the column of liquid by making the top

of the cylinder air tight, and inserting a tin tube several feet long, which must be kept filled with the liquid. All the substantial advantages, however, of this method may be obtained without pressure. For operating on very small quantities of a substance, an adapter or the neck of a broken retort may be used, by loosely stopping the lower and smaller end with a piece of cotton.

Soubeiran has adapted to Boullay's filter a receiver of tin, from which the filtered liquor may be drawn off by a stop-cock at the most dependent part. An apparatus of this kind is represented in the margin. One of the most important points, in conducting the displacement process, is to keep the ingredients constantly saturated, with a stratum of the displacing liquid over them. To avoid the necessity of constant supervision to effect this, the arrangement represented in the right-hand one of the two marginal figures may be used. An ordinary bottle containing the menstruum, with a tube of a quarter of an inch bore passing through the cork, is inverted over the percolator, with the end of the tube dipping in the liquid above the ingredients.*

For powders which swell much on the addition of water a conical percolator is greatly preferable to those of a cylindrical or nearly cylindrical shape; and a common glass funnel may be used. Indeed, most of the ordinary tinctures may be prepared with great facility by means of glass funnels, which may be had of all capacities, from that of half a pint to that of two gallons. But, in order that the process of percolation may be successfully employed, it is necessary to lay down various precepts for the guidance of the learner; and even those best instructed theoretically can hardly hope to avoid errors, unless they have by practice thoroughly qualified themselves for operating correctly. An inference from this fact is that, in the execution of pharmaceutical processes, when an alternative between percolation and another method is offered, the wholly inexperienced operator should prefer the latter. Under the heading of "general officinal directions," a few pages in advance, will be found valuable precepts for conducting percolation, to which, as well as to the explanations that may be deemed necessary, the pharmaceutical student is referred.†

* For an ingenious apparatus, invented by Dr. E. R. Squibb, in which the same object is obtained by means of a bottle placed on a higher level than the percolator, and connected with it by means of two syphon tubes, see *Am. Journ. of Pharm.*, March, 1858, p. 99.

† Dialysis. This name has been given by Mr. Graham, Master of the Mint, London, to a process based upon the different diffusibility of liquids, by which mixed substances may often be separated from each other, and important ends thus obtained. Though not yet officinally employed in pharmacy, it is capable of beneficial application in many instances by the apothecary, and therefore demands a brief description. It is well known that substances, in the liquid state, have the property of diffusing themselves, by their own inherent power, through other liquids. Mr. Graham ascertained that this property was possessed by different substances in very unequal degrees; and, on pushing his investigations into the subject, found that there was good reason to divide bodies into two classes based on their degree of diffusibility, one class consisting generally of crystallizable substances, which are highly diffusible, the other of uncrystallizable substances, especially

Crystallization. Numerous chemical substances, in becoming solid, when their solutions are evaporated, take on certain regular forms. The bodies having such forms are called *crystals*, and the process for obtaining them, *crys-*

those capable of forming a gelatinous mass with water, which diffuse themselves very slowly. The first class Mr. Graham proposed to name *crystalloids* from their property of crystallizing, the second *colloids* from their resemblance to glue in the power of gelatinizing. An example of the first we have in sugar, of the second in gum. Another discovery made by Mr. Graham was that a thin layer of gelatin in the form of jelly, interposed between two liquids, offered no obstacle to the passage of the crystalloids from one to the other, while it completely prevented the passage of the colloids; and this property he found to belong not only to gelatin, but to other substances having a similar molecular constitution, as bladder, parchment, paper sized with starch paste, &c., of which the most convenient is the texture known as *parchment-paper*, prepared by immersing unsized paper in a cold mixture of two measures of sulphuric acid and one of water.

Upon the principles here stated, Mr. Graham contrived a very simple apparatus, which he called the dialyser, and a figure of which is given in the margin. It consists of two parts, one a circular glass recipient (*b*), about a foot in diameter and six inches deep, the other (*a*) a similar circular vessel from six to ten inches in diameter and about two inches deep, the circumference of which consists of a band of gutta-percha, and the bottom of a circular piece of parchment paper, the edges of which are brought over the lower rim of the gutta-percha band nearly to the top, and fastened outside of it by a string, or by a narrow hoop of gutta-percha. The first part, or circular basin, is to receive distilled water, and should contain from five to ten times the quantity of the liquid that may be introduced into the smaller vessel. The latter is to float upon the surface of the water in the former, and is to receive the liquid to be submitted to dialysis, which should not be more than half an inch deep on the paper bottom. It is important that the parchment-paper employed should have no rent or aperture, and should be brought well up, and well secured on the outside of the gutta-percha, to prevent the liquid from passing between them. If any liquid containing a mixture of colloid and crystalloid matter be placed in the floating vessel, after some hours it will be found that a portion of the latter has passed through the parchment-paper, and is held in solution by the distilled water of the larger vessel, while the colloid matter remains. The distilled water thus impregnated is called the *diffusate*. The parchment-paper, or any similar material used as the septum, is applicable to the dialysis only of substances held in watery solution, and will not answer for alcoholic or ethereal liquids. M. Guignot has found that *porous or unglazed earthenware* is capable of acting efficiently as a dialysing septum. Thus, a porous vessel containing pure water was placed in another vessel containing a solution of sugar and gum; and, at the end of 24 hours, a greater portion of the sugar had passed into the inner vessel, but not a discoverable particle of gum. (*Pharm. Journ.*, N. S., iv. 317.) It is obvious that very different arrangements might be made to accomplish the same ends. Thus a bladder containing a similar mixture, suspended in a jar of distilled water, should yield similar results. Graham's apparatus is preferable to others only for its convenience.

It is not our purpose to treat of all the applications of the process of dialysis. We shall refer to those only in which it may prove useful to the pharmaceutist. 1. It facilitates in many instances the separation of the active matter of any artificial or natural mixture, to a considerable extent, from the inert and useless, the former being very often crystalline, and the latter colloidal. Thus infusions or decoctions of medicines, such as opium, belladonna, aconite, &c., submitted to dialysis, might give up more or less completely their crystalline principles, such as the salts of morphia, atropia, aconitia, &c., to the water, while the gummy, resinoid, extractive, and colouring matters, &c. might remain behind. In effecting the analysis of organic bodies, one of the most embarrassing problems is to get rid of the inert principles, which interfere with the action of chemical reagents; and the process of dialysis may here often be brought to the aid of the operator. 2. In searching for poisons in organic mixtures, as in the contents of the stomach, in which the application of tests is often rendered abortive by the colloidal matter present, the problem of the presence of the poison may be sometimes solved by submitting the suspected matter to dialysis. The poison will often be found in the diffusate, separated from the other matters, and may then be detected by the ordinary tests. Arsenious acid, morphia, strychnia, brucia, and digitaline have been tried in this way, and given successful results. (See *Am. Journ. of Pharm.*, Sept. 1864, p. 414.) 3. In pharmaceutic operations, it often happens that salts and other crystallizable substances are thrown away as refuse matter, because they would not repay the cost of time and material necessary for their recovery. It is possible that, by this simple inexpensive process, these substances may be separated from the useless matters and thus saved. 4. An economical application has recently been made

tallization. The most usual method is by the evaporation of solutions, either spontaneously, or by heat. The extent to which the evaporation should be carried depends on the solubility of the substance. The proper degree of concentration is attained, when a drop of the solution, removed to a cool glass plate, deposits well-formed crystals. When set aside to crystallize, a solution should not be disturbed until deposition ceases. The crystals are large in proportion to the slowness of the cooling of the solution, to effect which the vessel is sometimes set in the drying closet, and sometimes left to cool with the sand-bath. The deposition of crystals is facilitated by suspending some insoluble substance, as wood, or sheet lead, in the solution, or crystals of the same substance, which are thus increased in size. When it is desirable to have small acicular crystals, the solution should be cooled rapidly, and stirred constantly meanwhile.

Crystallization is one of the best means of purifying many substances; the impurities remaining wholly or chiefly in the residual liquid called *mother-water*. Fine silky crystals, which retain their mother-water by capillary attraction, must be dried by strong expression in a linen bag. The finest silky crystals may be entirely freed from adhering liquid, by placing them in a funnel which fits closely to one of the necks of a double-mouthed bottle, and fitting a tube to the other, through which air is drawn. The current of air, in passing through the funnel, carries the water with it, and dries the crystals perfectly.

Effects of Heat. The operations which require a heat greater than that used in digesting are *liquefaction*, *fusion*, *calcination*, *ustulation*, *incineration*, *distillation*, *sublimation*, and *reduction*.

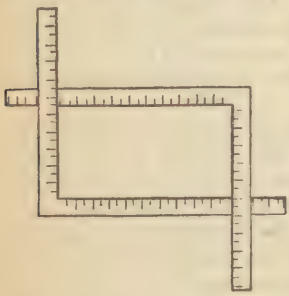
Liquefaction is the melting of those substances that become soft previously to fusion, as wax, tallow, plaster, &c. The heat employed is always below that at which charring takes place.

Fusion is the melting of those substances which pass immediately from the solid to the fluid state. It is employed in pharmacy in preparing nitrate of silver and caustic potassa for casting into cylinders. The former must be melted in a porcelain, the latter in an iron crucible. The moulds in which they are cast are formed of two thick plates of cast-iron or silver, with semi-cylindrical grooves that fit accurately to each other. Fusion is also used in preparing the glass of antimony.

Calcination is the term applied to the changes produced in mineral substances by intense heat, not attended with fusion, and leaving a solid residue, and is often synonymous with oxidation. The term *ustulation* is restricted to the metallurgic operations of roasting ores, to drive off the volatile matters, as arsenic, &c. Calcination is often used to express the ustulation or burning of carbonate of magnesia. This is to be performed in an earthen vessel at a red heat. Exposure to the heat of a potter's furnace, during the burning of the kiln, is an excellent mode of performing the operation. More commonly the carbonate is burnt in an iron pot, which is objectionable; as the heat soon oxidizes the iron, and the oxide scales off and mixes with the magnesia, which is seldom free from iron when prepared in this way.

Incineration, as the name expresses, is the operation of burning substances for the sake of their ashes. It is performed in obtaining phosphate of lime, the Cornu Ustum of the late London Pharmacopœia. The bones are burnt in an open fire until all the combustible matter is consumed.

of the process to the restoration of salted meat to the fresh state. If some salt beef with its brine be enclosed in a bag of material suitable for dialysis, as of untanned leather, and the bag be immersed in sea-water, in the course of some days the beef and brine will have been rendered sufficiently fresh for use, the salt having passed out into the sea-water. (*Chem. News*, May 28, 1864.) (See, on the subject of dialysis, papers by Prof. Redwood in the *Pharm. Journ.*, April, 1862, p. 515, and by Prof. Procter in the *Am. Journ. of Pharm.*, July, 1862, p. 312.)—*Note to the twelfth edition.*



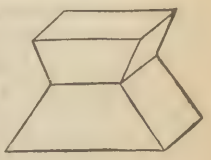
Notwithstanding the very important aid promised by this process to pharmacy when first announced, we are informed that it has proved less practically useful than was hoped; as the great dilution of the diffusate renders it liable to chemical change in the case of organic substances, and makes also a great amount of evaporation necessary. (*Note to the thirteenth edition.*)

Reduction is that operation by which certain binary compounds of the metals are brought to the metallic state, by heating them alone, or with some substance capable of attracting the combined substance and setting the metal at liberty. Arsenious acid is thus reduced by heating it with charcoal, and oxide of iron, in powder, by heating it in a current of hydrogen. When, in the reduction of metallic compounds, some third substance interferes with the process, as silica, a substance capable of combining with this is added, called a *flux*.

Dispensing of Medicines. A large portion of the operations of the apothecary is performed in the shop extemporaneously. In dispensing medicines from the counter, he is continually called upon to put his previous knowledge in practice, and often to substitute extemporaneous for the regular officinal formulas. There is no part of his business which requires, for its proper performance, so much ready knowledge and so accurate a judgment. A few directions, suggested by running the eye over the list of preparations of the Pharmacopœia, may be found useful.

Aromatic Waters. It may sometimes be necessary for the apothecary to make extemporaneously an aromatic water, not usually kept in the shops. In this case he is to prepare it by rubbing two drops of the essential oil with from four to six grains of carbonate of magnesia for every fluidounce of water, and filtering.

Plasters. It is sometimes desirable to apply plasters prepared from herbs. These may be made extemporaneously, by mixing the soft extract of the plant with about twice its weight of melted adhesive plaster. The most suitable material on which to spread plasters is soft white leather. A margin of half an inch should be allowed to remain around the plaster. The plaster iron or spatula may be heated over the large spirit lamp, figured in page 921. A skilful apothecary will be able to spread the plaster uniformly and evenly, without overheating it so as to corrugate or penetrate the leather. A convenient instrument for determining the size, and preserving a straight edge, consists of two squares made of tin and graduated to inches, as in the annexed figure; or pieces of paper may be cut out and pasted on the leather, so as to enclose a space of the required dimensions. The plaster should first be melted on a piece of brown paper, and then transferred to the leather, in order to prevent its being applied at too great a heat. For all the officinal plasters, the apothecary should have small tin trays open on one side, on which to melt them. If the plaster to be spread is a very large one, it is better to liquefy the material in a capsule, and add it to different parts of the leather as it is wanted, till the whole is covered. For the description of an apparatus for spreading plasters, see *Emplastra*.



Decoctions and Infusions. These are often ordered in prescriptions in the quantity of a few ounces. A very convenient vessel for preparing them is the common nursery lamp, which consists of a cylindrical vessel, open at one side to receive a spirit lamp, and at the top to receive a teapot or tin boiler. The *infusion mug* of Mr. Alsop, of London (see *Infusa*), which consists of a queensware vessel, with a perforated diaphragm of the same material resting on a ledge at one-third of its height from the top, is the best instrument for this purpose. The material to be infused is placed on the diaphragm, and the boiling water poured on till it rises over the ingredients. No stirring is necessary, and the process is accomplished rapidly. Infusions and decoctions may be kept during hot weather, and for many months, by straining them *while hot*, and pouring them at once into bottles provided with accurately ground stoppers. The bottle must be quite filled; the stopper being made to displace its own bulk of the liquid. A common bottle with a perforated cork stopper may be used, if the hole be instantly closed, and the cork covered with sealing wax. The hotter the liquid and the freer from air bubbles, the better will the infusion keep.

Neutral Mixture and Effervescing Draught. Neutral mixture is known to be saturated perfectly, when it does not affect litmus paper either in its blue state, or reddened by an acid. The carbonic acid, extricated in its preparation, combines at first, without effervescence, with the remaining carbonate, and forms a bicarbonate. This circumstance may lead, unless the solution be tested, to the supposition that the mixture is saturated. For preparing the effervescing draught, it is advisable to keep in the shop a solution of carbonate of potassa containing an ounce to the pint. The silica which this salt contains precipitates after a few weeks, and leaves a perfectly clear solution; whereas that prepared at the time it is to be used always becomes turbid after being saturated.

Extemporaneous Mixtures. In preparing these by direction of the physician, it is of the first importance to mix the ingredients in the manner best calculated to ensure a smooth and readily miscible compound, without grittiness or imperfectly comminuted portions, when a part of the constituents may be insoluble. Kino and extract of rhatany should be first dissolved in boiling water, when admissible. If an aromatic water is directed, they should be rubbed to powder, mixed with the insoluble ingredients, if any, and the water gradually added, the whole being triturated till smoothly mixed. Emulsions of the gum-resins should be rubbed till all the particles are softened, and then strained, if any extraneous matter is present. Water can be saturated with camphor by means of carbonate of magnesia, and an aqueous mixture of any strength may be made with it, by triturating the camphor with magnesia, and shaking the mixture before using it. Camphor softens the gum-resins, and solid fats and oils, and may be rendered permanently miscible with water, in considerable quantity, by trituration with a fifth part of myrrh. In preparing oily emulsions in which gum arabic, or gum and sugar are the medium, a sufficient quantity of water must be added (generally about twice their weight) to convert them into a thick mucilage before adding the oil, which must then be thoroughly mixed with the mucilage, and the remaining water added gradually with great care. Gum arabic is best suited for this purpose in a powder somewhat less fine than as ordinarily used. Ether is rendered more soluble in water by trituration with spermaceti. The mixture should be filtered to separate the superfluous spermaceti. If elaterium is to be incorporated in a mixture, it should be first rubbed with a little alcohol, then with sugar or syrup, and lastly with the other ingredients. When a few drops of croton oil are to be suspended in a mixture, the latter will be more permanent if a little olive oil be added with the croton oil to increase its quantity. Mixtures that contain the resinous tinctures, should also contain syrup, with which the tincture should be first mixed, and the water then added very gradually. If a mixture is to contain laudanum and a fixed oil, the former should be first mixed with the syrup and the oil afterwards incorporated, and lastly the water. The mixture will not otherwise be uniform. When a considerable quantity of sugar is added to a mixture, it is best to use syrup, employing a fluidrachm of syrup for each drachm of sugar, and making allowance for the water contained in the syrup, which equals half its bulk.

Powders. Powders are often mixed together with difficulty, by means of a pestle and mortar, on account of their differing greatly in weight, or of their softness and compressibility, as charcoal and magnesia, or rhubarb and magnesia. In these cases the mixing should be completed with a spatula on paper. In dividing powders into doses, it is very desirable to fold the packages neatly and of a uniform size. The *powder folder* represented in the figure is very useful for this purpose. It may be made of mahogany or other hard wood. Instruments of this kind with a movable cheek, so as to be widened or contracted by a screw, and made of brass, are used in some shops. When volatile or deliquescent substances, as camphor and carbonate of potassa, are prescribed in several powders, these should be enveloped separately in tin-foil or waxed paper; and, when the number of doses is more than two, they should be enclosed in a paper box.

Pills. In ordering pills care must be taken to avoid the use of deliquescent salts, and to deprive those which are efflorescent of their water of crystallization. The mass must be thoroughly incorporated previously to being divided; and this is particularly important when extracts of different degrees of hardness enter into the composition. A section of the mass should be throughout of uniform colour and consistency. Pills are to be rolled and preserved in powdered liquorice root, or lycopodium powder, which ought to be kept for use in a tin box with a perforated lid, like a pepper-box. The liquorice root is preferable on the pill-machine, as finer and more adhesive; the lycopodium in the pill-box, as less liable to attract moisture, and not disposed, like the former, to become mouldy. When pills are of too soft a consistence, a little liquorice powder may be incorporated with them to render them more firm. Pills, into the composition of which gum arabic enters, should be softened with syrup, and not with water, as the latter renders the mass difficult to roll. For further remarks relative to the formation of masses for pills, see *Pilulæ*.

Gum-resins. Gummi-resinæ. The method of treating gum-resins, now that it has ceased to be a special subject of officinal direction, may be appropriately considered in this place. Gum-resins are concrete natural juices of plants obtained by spontaneous exudation or incision, and consisting of gum and resin, associated for the most part with more or less volatile oil, and frequently with other substances, such as extractive, bassorin, starch, wax, and various salts. The gum and resin are essential ingredients, but exist in very different proportions in the different varieties. All the gum-resins are partially soluble in alcohol and in water, but completely so in neither of these liquids. Diluted alcohol, on the contrary, dissolves them almost entirely, especially if assisted by heat. With water they form an opaque emulsion; the resin, essential oil, and other insoluble constituents being held in suspension by the dissolved gum. They are to a certain extent soluble in vinegar. Upon several of them, especially myrrh and ammoniac, carbonate of potassa so reacts as to render them soluble in water, or capable of being permanently retained in suspension by that liquid. A good method of effecting their suspension in any watery vehicle, is to rub them with a few drops of pure almond oil so as to form a smooth paste, and then very gradually to add the liquid, continuing the trituration. In forming an emulsion with myrrh very rich in oil and resin, the union with water is greatly facilitated by rubbing the gum-resin, after it has been well beaten, with a little gum arabic before adding the water.

They are often so impure from admixture of vegetable and mineral substances, as to be unfit for use until purified. Various modes of effecting this object have been practised. Some of the gum-resins, as galbanum, are so far fusible, that they may be rendered sufficiently liquid by heat to admit of straining through a hempen cloth. Care should be taken in this process not to apply too great a heat, and it is best that the liquefaction should be effected by means of a water-bath. But several of them, as assafetida and ammoniac, are not sufficiently fusible at the temperature of boiling water to admit of being strained with facility. As they are usually brittle and pulverizable when very cold, they may be freed from the coarser impurities by powdering them in the winter season, and sifting the powder, which afterwards agglutinates with warmth. This plan is recommended by Mr. Brande in relation to assafetida, ammoniac, and galbanum. When boiled with hot water, any of the gum-resins, though not dissolved, will form a semi-liquid mass capable of being strained; and this was the method employed by the London College for their purification. It is liable to the objection that a portion of the volatile oil, upon which their medical virtues in part depend, is driven off; and the gum-resins thus prepared are adapted more especially for external use. The French pharmaceutists purify these substances by dissolving them in diluted alcohol, filtering, and evaporating the solution. This process, though liable in a still greater degree than that of the London College to the objection of diminishing the virtues of the medicine by driving off the essential oil, has the advantage of completely separating all insoluble substances, however minutely divided, such

as fine sand or other earth, which might pass through the pores of a hempen strainer. For internal use, it is best to select the gum-resin so pure as not to require purification. M. Constantin recommends, as an effectual method of producing permanent homogeneous emulsions with the gum-resins, to put into a marble or porcelain mortar the quantity directed of the gum-resin, in small pieces, to add about four times its weight of alcohol, to set this on fire and triturate with a porcelain pestle until the alcohol is consumed and lastly to rub the soft mass, thus produced, with the liquid gradually added. (*Journ. de Pharm.*, xxvi. 39.)

Suppositories and *lozenges* or *troches* are other preparations often extemporaneously made by the apothecary, which are not described here; as they will be found sufficiently treated of, in a general way, in a subsequent part of this work, in connection with the several substances belonging to them.

Implements. The proper cleanliness of his vessels is an object of great importance to the apothecary. Open vessels, as mortars and measures, are easily cleansed, and should be wiped dry immediately after being washed. Fats and resins are readily removed by pearlash, or tow and damp ashes, or sand; red precipitate and other metallic substances by a little nitric or muriatic acid; Prussian blue by means of pearlash. Bottles may be cleansed from the depositions which accumulate on their sides and bottoms from long use in the shops, by a few shreds of grocers' paper, and a little clean water. They are to be shaken so as to give the paper and water a centrifugal motion, which effectually removes the dirt from the sides. They may be freed from oil by a little strong nitric acid, after the action of which water will thoroughly cleanse them. Long sticks armed with sponge, or dry linen or cotton cloth, should be provided for wiping dry the interior of flasks and bottles.* A wire, bent at the end into a sort of hook, will be found useful for getting corks out of bottles. Wire instruments with three prongs are made specially for this purpose. In the absence of these, a loop of twine will often be found convenient for effecting the same object. When the glass stopper of a bottle is fast, it may often be loosened by gently tapping its sides alternately with the handle of a spatula. Sometimes a drop or two of oil, alcohol, chloroform, or water, will soften the cementing substance. It will sometimes answer to wrap the stopper in a cloth, insert it in a crevice or hole, in a table or door, and twist the bottle gently and dextrously. Sometimes the stopper may be loosened by quickly expanding the neck in the flame of a lamp, and tapping the stopper before the heat has reached it. The bottle should be constantly turned in the hand during the heating process, to avoid unequal expansion and fracture. In the absence of a flame, a piece of twine, turned twice around the neck and drawn back and forward rapidly, will soon heat it sufficiently in most instances. When the stopper of a bottle containing caustic alkali adheres, in consequence of the neck not having been wiped thoroughly dry, it is almost impossible to loosen it, and the neck must be cut off. The adhesion in such cases

* The odour of volatile oils, and other strong-smelling substances, such as musk, may be removed from bottles, mortars, &c., by means of the pulp of bitter almonds or peach kernels, bruised peach leaves, or other substances containing hydrocyanic acid. But fatty matters should first be removed by an alkaline solution, and resins by alcohol. (*Journ. de Chim. Méd.*, 1845, p. 535.) It is asserted that the powder of black mustard has the same effect. (*Ibid.*, 2e sér., iii. 727.)

In a communication by Prof. Procter to the *Am. Journ. of Pharm.* (Nov. 1868, p. 510), the alternate use of *benzine* and solution of one of the alkaline carbonates with lime, is strongly recommended for the cleansing of cod-liver oil bottles, which are often returned to the shop with the oil, thickened by exposure, adhering both to their inner and outer surfaces. The benzine is first used, and then the alkaline solution with lime; the operation can be repeated if needful; and the whole process is completed by a thorough rinsing with water. For more precise particulars the reader is referred to the journal. (*Note to the thirteenth edition.*)

It is sometimes difficult to cleanse glass and porcelain to which organic matters have long adhered. These sometimes become so hard and dry as to resist solvents. C. Brunner recommends, in such instances, to moisten the surface to be cleansed with strong sulphuric acid, to sprinkle on the acid some powdered bichromate of potassa, and to let the vessel stand for some hours in a warm place. The organic matter is thus destroyed and may easily be washed away. (*Chem. Gaz.*, no. 410, p. 430.)

may be prevented by dipping the stopper before insertion in melted paraffin, on which the alkalies have no action. It is said that organic substances, which are altered by exposure to light in ordinary glass bottles, undergo no change when contained in orange-coloured bottles.

The apothecary should be provided with spatulas of wood, whalebone, and horn, as well as of steel. It should be an invariable rule to clean every knife and graduated measure immediately after it is used, and to put the dirty mortars apart from the clean. Too much particularity and order in all the minute details of the shop cannot be practised. The counters should be cleaned every day, and wiped as often as they become dusty. The scales should be thoroughly cleaned every week, and wiped always after using them for dusty substances; and the prescription *balance* should be kept carefully enclosed in a glass case, and the dishes wiped after each time of using. The beam should occasionally be wiped with a soft cotton or silk cloth. The mortar stand should pass through the floor and cellar into the ground, so as not to jar the counter during the contusion of substances, and thus injure the balance. Bottles should be replaced as soon after being taken down and used as possible, and should on no account be changed from their accustomed place on the shelf. For the preservation of leaves, flowers, aromatic powders, calomel, and other medicines to which light is injurious, the bottles should be coated with tin-foil, or with black or orange-coloured varnish.

No apothecary should be unprovided with a set of *troy weights*, as without them he will find it difficult to comply with the officinal directions for the preparation of his medicines; and the drawer in which his smaller weights are kept should be clean and free from dust, so that the weights may be accurate. In dispensing medicines, no vial or parcel should be suffered to leave the shop without its appropriate label; and this, in the case of prescriptions, should always be the physician's direction as to the manner of taking it, and not the name of the medicine, unless it be so directed by him. The prescription, or a copy of it, should be retained and numbered, and the same number marked on the parcel or bottle. Everything connected with the shop, and the dispensing and putting up of medicines and parcels, should be characterized by *neatness*, *accuracy*, *system*, and *competent knowledge*.

The apprentice who desires to qualify himself for his business, should carefully study Turner's, Graham's or Fownes's Elements of Chemistry, Mohr and Redwood's Practical Pharmacy, Parrish's Treatise on Pharmacy, and Morfit's Chemical and Pharmaceutical Manipulation, which may be termed the handbooks of his profession. D. B. S.

General Officinal Directions.

As all the processes of the United States and British Pharmacopœias are either described or fully detailed in the following pages, it is proper that the prefatory explanations in these works should be introduced in this place, in order that the reader may be prepared to understand the precise signification of the terms employed.

Weights. The U. S. Pharmacopœia recognises the *troy* or *apothecaries'* pound, and its divisions of ounces, drachms, scruples, and grains, for the expression of weights, but actually employs, in its processes, only the grain and ounce. The following explanations are given on the subject of weights.

"In order to avoid the danger of mistakes from confounding the troy and avoirdupois pounds, the term, *pound*, is disused in the formulas of this work, and the desired weight is expressed in ounces, each containing four hundred and eighty grains. This ounce is always printed *troyounce*, to guard against the error of substituting for it the avoirdupois ounce, consisting of four hundred and thirty-seven and a half grains. The drachm and scruple are also disused, and replaced by their equivalents in grains. It is highly important that persons engaged in preparing medicines should be provided with troy weights. But those who are not so provided can make their avoirdupois weights available as substitutes for troy weights, by bearing in mind that 42·5 grains, added to the avoirdupois

ounce, will make it equal to the troy ounce; and that 1240 grains, deducted from the avoirdupois pound, will reduce it to the troy pound." *U. S.*

As the common weights of the country are the avoirdupois weights, and every apothecary is in possession of the lower denominations of the apothecaries' weight, viz. grains, scruples, and drachms, there can be no difficulty in complying with the officinal directions. The British Council, in their recently published Pharmacopœia, have abandoned the troy weights formerly employed by the London and Edinburgh Colleges, and substituted the avoirdupois pound and ounce, the former of 7000 grains, the latter of 437·5 grains; conforming in this respect with the Dublin College, but adhering to the old grain, and rejecting all intermediate divisions. It is a subject for congratulation that the Dublin drachm and scruple, of 54·68 grains and 18·22 grains respectively, have been abandoned

Both in the *United States* and *British Pharmacopœias*, with the exception, in the former, of the mineral acids, fixed oils, and chloroform, the quantity of fluids is generally indicated by the liquid measure, consisting of the gallon and its divisions of pints, fluidounces, fluidrachms, and minims. It is highly necessary that the apothecary should understand that this distinction is rigidly observed, in this work, in all the details which follow, and that, whenever the simple terms pound, ounce, and drachm are employed, they must be considered as belonging to the denomination of troy weight, unless when otherwise expressly intimated. This caution is the more necessary, as these terms are often confounded with the corresponding divisions of liquid measure, viz. the pint, fluidounce, and fluidrachm. (See Tables of Weights and Measures in the *Appendix*.)

Measures. The U. S. Pharmacopœia adheres to the old wine gallon and its divisions of pints, fluidounces, fluidrachms, and minims; but actually employs, in its processes, no denomination of measure higher than the pint. In the British Pharmacopœia the Imperial gallon and its divisions, before used by all the British Colleges, have been retained. This discrepancy is very unfortunate, as no one denomination of the Imperial measure corresponds exactly with the same denomination of the wine measure; and the formulas, therefore, of the British Council, so far as measures are concerned, when they agree in terms with those of the United States Pharmacopœia, differ from them in reality; while in other cases, though differing in terms, they may be quite or very nearly identical. It is very important that the apothecary should bear this distinction in mind; and, when he has occasion to carry into effect one of the foreign formulas, that he should make the due allowances. He will find, among the Tables in the *Appendix* of this work, a statement of the relative value of the several denominations of the Imperial and wine measures, and, by consulting this statement, will be enabled to convert the former into the latter without difficulty. We have endeavoured to obviate, as far as possible, this source of inconvenience, if not of danger, by indicating in our accounts of the British processes the kind of weight or measure intended, whenever the discrepancy is such as to be a point of any importance. Though the Imperial fluidounce, fluidrachm, and minim differ somewhat from the wine measures of the same denomination, yet that difference is so small that we have not always deemed it necessary to make them objects of special notice. At the temperature of 60° F., the U. S. pint of distilled water weighs 7291·2 grains, and the fluidounce 455·7 grains; while the Imperial pint of distilled water, at the same temperature, weighs 7000 grains, and the fluidounce 437·5 grains. The measures kept in the shop should be graduated according to the divisions of the wine gallon; as this is recognised by our own officinal standard.

Temperature. When there is occasion to indicate the temperature, Fahrenheit's thermometer is employed in the *U. S.* and *Br. Pharmacopœias*. In the former, the term *gentle heat* indicates any temperature between 90° and 100°.

Specific Gravity. In both *Pharmacopœias*, when the specific gravity of a body is given, it is considered to be at the temperature of 60° of Fahrenheit.

Saturation. The *U. S. Pharmacopœia* states that "when an acid or alkali is directed to be saturated, the point of saturation is to be ascertained by means of litmus and turmeric, in the way usually followed by chemists." For this

purpose litmus or turmeric paper is usually employed; the latter being rendered brown by the alkalies, the former being reddened by the acids, and having its blue colour restored by the alkalies. (See *Lacmus* and *Curcuma*.)

Containing Vessels. In the *U. S. Pharmacopœia* it is ordered that, in all cases in which bottles are directed to be well stopped, they must be closed with glass stoppers. In the late *London Pharmacopœia* it was directed that, when not otherwise ordered, glass, porcelain, or stoneware vessels should be used for preparing and preserving medicines, at the same time guarding especially against the employment of earthen vessels glazed with lead. The same College also directed that acid, alkaline, and metallic preparations, and salts of every kind, be kept in stopped glass bottles, which, for certain substances, should be of black or green glass.

Percolation, or *Filtration by Displacement.* In relation to this process, the following directions are given in the *U. S. Pharmacopœia.*

"The kind of filtration, known as *percolation* or the *process of displacement*, directed in this Pharmacopœia, consists in subjecting a substance or substances, in powder, contained in a vessel called a *percolator*, to the solvent action of successive portions of a menstruum, in such a manner that the liquid, as it traverses the powder in its descent to the recipient, shall become charged with the soluble portion of it, and pass from the percolator free from insoluble matter.

"When the process is successfully conducted, the first portion of the filtered liquid, or *percolate*, will be nearly saturated with the soluble constituents of the substance treated; and, if the quantity of menstruum be sufficient for its exhaustion, the last portion will be nearly destitute of colour, odour, and taste.

"The percolator should be either conical, or nearly cylindrical with a conical termination at the smaller end, and provided internally with a porous or colander-like partition or diaphragm, resting transversely immediately above its neck, for the support of the powder. Ordinary glass funnels, varying in capacity from one to eight pints, are to be preferred for most of the operations requiring percolation in this Pharmacopœia; but percolators may also be made of earthenware or tinned iron, especially of the latter material when required of large size. Tinned iron, however, should not be used when the liquid acts chemically on the material. In the several formulas in which percolators are used, their form and material will always be designated when there is a preference in these respects. In cases in which these variations of the instrument are indifferent, the term percolator simply will be employed. When a funnel is used, a circular piece of muslin or of lint, pressed into the neck by means of a cork with notched sides, forms a good diaphragm; but in all cases a similar piece of muslin, moistened slightly with the menstruum, should be interposed between the diaphragm and the powder, to prevent the passage of the fine particles of the latter.

"The substance to be subjected to percolation, after having been reduced by sifting to a uniform powder, of the fineness indicated in the formula, is to be put into a basin with from one-fourth to one-half of its weight of the menstruum, and the two rubbed together until the powder is uniformly moistened.

"A portion of the powder is now to be carefully placed upon the diaphragm, prepared as above directed, and pressed gently until the muslin, resting against the sides of the percolator just above the neck, is covered with a uniform layer. The remainder of the powder is then to be transferred to the percolator, and compressed evenly and firmly, and the level surface covered with a circular piece of moistened muslin, so that the liquid poured upon it may penetrate equably, and not disarrange the powder.

"The percolator being now properly supported, with its neck in a bottle previously marked for the quantity or quantities of liquid to be percolated, the menstruum is to be poured on the muslin until the space above is nearly filled; and a layer of it must be constantly maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or until the requisite quantity of percolate has been obtained.

"If the fineness of the powder and its arrangement in the percolator have

been properly attended to, the percolate will pass out, by drops, with greater or less rapidity, according to the size of the percolator; but, if, by reason of accidental imperfection in the powder, or in the packing, the liquid pass more rapidly than this, the neck of the percolator should be obstructed by means of a cork until the requisite slowness has been attained.

"When the dregs of a tincture are to be subjected to percolation, after maceration with all the menstruum, the liquid portion should be drained off, the solid portion packed in a percolator as before described, and the liquid gradually poured on until all has passed the surface, when, immediately, sufficient of the original menstruum should be poured on to displace the absorbed liquid, until the prescribed quantity of the tincture has been obtained.

"*Fineness of Powders.* As different degrees of fineness are necessary in powders, according to their nature and mode of treatment, the special degree required is designated in the several formulas. For this purpose the terms very fine, fine, moderately fine, moderately coarse, and coarse are used;—the powder passed through a sieve of eighty or more meshes to the linear inch being designated as *very fine;* through one of sixty meshes, *fine;* through one of fifty meshes, *moderately fine;* through one of forty meshes, *moderately coarse;* and through one of twenty meshes, *coarse.*" *U. S.*

The principles of the process of percolation and the apparatus in which it is performed have already been presented in sufficient detail. (See *page* 931.) The advantages of the process are, that the active soluble principles of medicinal substances are in general extracted by it more speedily, thoroughly, and economically than by any other mode; that concentrated solutions of these principles are more easily obtained; and that no portion of the impregnated menstruum need be lost by remaining in the solid mass. It is, however, liable to the objection, that considerable experience and skill are necessary to carry it properly into effect, and that, if improperly performed, it must often result in preparations very different from those contemplated in the formulas. It should not, therefore, be resorted to in the fulfilment of officinal directions, when any alternative is given, unless by individuals who have acquired the requisite skill by practice.

The sources of failure in this process are chiefly an improper degree of comminution in the substance to be acted upon, and an improper condition of the mass after it has been introduced into the instrument. If the material be in too fine a powder, it resists or obstructs the passage of the fluid; if too coarse, it allows the fluid to pass too rapidly, and at the same time opposes its cohesion to the solvent power of the menstruum. If merely bruised, especially if fibrous pieces of some length are intermixed, it causes the fluid to make irregular channels, and thus to act upon it partially. An improper packing of the material occasions similar inconveniences. If too compact it impedes, if too loose it injuriously facilitates the passage of the solvent, and if not uniform it produces an irregular flow, which necessarily vitiates the result. The liquid, finding an easier passage at one part than another, flows more rapidly in that direction, and thus makes channels by which it may in great measure or wholly escape, with little influence upon the mass. Besides, the uniform progression, by which each superadded portion displaces that immediately beneath it, is broken, the successive layers become intermingled, and thus one of the peculiar advantages of the process is lost. The following observations may be of some use in assisting the operator to avoid these consequences.

The solid material should always be in the state of a uniform powder, to which, when not required to be fine, it may be conveniently brought by grinding in a common coffee-mill. If its texture be very hard, firm, and not easily permeable by moisture, as in certain barks, woods, and ligneous roots, it should be finely powdered. If, on the contrary, the texture be loose and spongy, and especially if the material be disposed to swell up and form a viscid mass with water, so as to impede percolation, as in the case of gentian and squill, the powder should be coarser; though the substances which require this treatment when water is used, may not require it with another solvent, as alcohol or ether.

The difficulty, however, arising from the swelling of the material is now almost entirely obviated by the employment of conical percolators, such as glass funnels, which by their shape allow the free expansion of the material upward, and thus prevent compression. Though funnels have been long in use as percolators, the principle of their favourable action was, we believe, first suggested by Prof. Procter. To secure uniformity in the powder, it should always be passed through a sieve before being used; and the proper degree of fineness is secured by having the number of openings in the linear inch of the sieve duly regulated. According to Prof. Grahame, of Baltimore, the sieve should generally have 60 meshes to the linear inch, especially for tinctures; but for substances which must be used in coarse powder 40 meshes are preferable. In the U. S. Pharmacopœia, the degree of fineness varies from 20 to 80 meshes to the linear inch, and, with great propriety, the precise degree of fineness adapted to each substance is indicated, in the several preparations, by the use of the terms *very fine*, *fine*, *moderately fine*, *moderately coarse*, and *coarse;* these terms having their exact value determined by the preliminary directions above quoted.

It has generally been considered advisable, before introducing the material into the instrument, to mix it with a portion of the solvent, and allow it to stand for some time in another vessel. It thus becomes more penetrable and more easily acted on by the menstruum, admits of a more uniform packing, and, if liable to swell with water, undergoes this expansion where it cannot have the effect of checking percolation. Opinion, however, has considerably changed on this point. It is obvious that, when it is desirable to have the first portion of the percolate as concentrated as possible, it is necessary that the powder should be no further moistened than may be essential for proper packing in the instrument. When previously mixed with the powder, the portions of liquid which first pass will have only the strength acquired by the maceration; whereas, when added to the powder but slightly moistened in the percolator, each particle of the menstruum passes successively, along the whole line of its descent, from particle to particle of the powder in all its strength, taking something from each as it descends until completely saturated; and it is also obvious that the higher the column, that is the greater the depth of the packed powder, the greater will be the chance of complete saturation. Besides, since the introduction of conical percolators into use, the disadvantages of compression from swelling have been so far obviated that the previous maceration is less needful on this account. Professor Grahame prefers that no more of the menstruum should be preliminarily employed than may be sufficient to dampen the powder, so as to enable it to be packed properly, and facilitate the passage of the liquid through the powder. The quantity must differ with the character of the powder, and is directed in each officinal preparation. As a general rule, it varies, as stated in the foregoing officinal directions, from one-fourth to one-half the weight of the powder. When concentrated solutions are not needed at first, as generally in the tinctures and infusions, the previous maceration with the menstruum cannot be of any material disservice. When employed, it may continue on the average about twelve hours; but a much shorter time will often answer. It has sometimes been recommended to perform this preliminary maceration in the displacement filter, its lower orifice being closed for a time. With some substances this may be done without disadvantage; but, in all those instances in which the material is liable to swell considerably with water, and thus to choke the passage, if a cylindrical percolator be used, the maceration should take place in another vessel.

The packing of the material in the instrument is that part of the process which most requires experience in the operator, and about which the least precise rules can be given. When mixed with a considerable portion of fluid, it will often subside of itself into the proper state; but generally it requires some pressure, and the degree of the latter must be in proportion to the looseness of texture in the material; reference, however, being always had to its disposition to swell with water. Certain substances in which this property is found, such as gentian and rhubarb, must not be pressed compactly when water is the sol-

vent. As the percolation advances, and portions of the substance acted on are dissolved, the mass often becomes too loose, and requires to be again pressed down. Substances which are apt to form with the menstruum an adhesive and impermeable mass, such as the resins and gum-resins, may be advantageously mixed, in the state of coarse powder, with about half their weight of perfectly clean white sand, as suggested by the late Mr. Duhamel. (See *Am. Journ. of Pharm.*, x. 15.) The sand separates the particles of the mass, and allows the menstruum a readier access.

After the moistened material has been properly packed, the upper surface should be made quite level, and then covered with a circular disk of tin pierced with numerous minute holes, or, what is probably better, a circular piece of muslin as directed in the Pharmacopœia. If the disk be of filtering paper, as some have recommended, it should be kept in its place by pieces of glass rod. The solvent is thus made to enter into the mass equably, and prevented from forming partial passages by bearing upon one or a few points. The liquid is now to be introduced in successive portions, as stated in the officinal directions above given.

If the lower diaphragm of the percolator be duly covered with a close filtering material, the percolate will always be clear from the beginning. The best material for the purpose is, perhaps, a piece of fine patent lint. Prof. Procter informs us that he finds advantage in covering the tissue which may be placed on the diaphragm by a thin layer of sand. Should the filtrate, however, be from any cause turbid, it should be returned into the instrument, before the addition of any displacing menstruum; and the same thing should continue to be done, until the liquid comes away perfectly clear. If the percolation be too rapid, pressure may be made upon the upper diaphragm so as to render the mass more compact; or the instrument may be closed below for a time, as stated in the officinal directions. Hence the advantage of having a stop-cock near the lower end for regulating the discharge. In the absence of a stop-cock, a soft cork may be used, with a small groove cut lengthwise for a short distance from its smaller end. By withdrawing the cork until the groove appears, a passage for the fluid can be opened at will. But if due attention be paid to the fineness of the powder and the proper packing of it, there will seldom be any occasion for this caution. Dr. Squibb states that the liquid should escape at the rate of about one drop every two seconds, or about three fluidounces in an hour. (*Am. Journ. of Pharm.*, March, 1858, p. 98.) When the percolation is too slow, it may be increased by the pressure of a column of liquid, and this plan may sometimes be advantageously resorted to when the powder is very fine, or large masses of material are operated upon. (See *pages* 932–3.) When the object is to keep up a constant supply of the percolating fluid, it may be accomplished by filling a long-necked bottle or matrass with the fluid, and inverting it over the filtering instrument, with its mouth beneath the surface of the liquid in the latter.

Hot liquids may be used in the process as well as cold, and are sometimes preferable when the substance yields its active principles more largely at an elevated temperature. But there is often an inconvenience in employing hot water; as it dissolves or renders glutinous substances not affected by cold water, which are not requisite and may even be injurious in the preparation, and which tend to embarrass the process by filling up the interstices of the mass, and thus rendering it less permeable. An instrument has been invented by Mr. C. A. Smith, of Cincinnati, by which the menstruum is made to enter the contents of the percolator in the state of hot vapour, and, being condensed by means of a refrigerating vessel surrounding the percolator, passes out in the liquid form, highly impregnated with the soluble principles of the material operated on. (See *Am. Journ. of Pharm.*, xviii. 98.)

The first portion of filtered liquid is very strongly impregnated, and the portions which subsequently come away are successively less so. It is sometimes desirable to obtain the whole of the particular solvent employed. This end may be very nearly attained by adding, at the close of the process, enough of another liquid to supply the place of that retained in the mass. It was Boullay's idea,

that the whole of the liquid contained in the moist material might be thus driven out of it or displaced by the one added, without any admixture of the two. This, however, has been ascertained not to be exactly true; and, however carefully the process may be conducted, some mixture will take place. Hence, it is recommended, when one liquid is added in order to displace another, to introduce first a shallow layer of the same liquid with that contained in the mass. In some instances, the solvent, if consisting of two liquids, is resolved into these in the process. Thus, when myrrh is subjected to percolation with proof spirit, the first liquid which comes away is alcohol holding the oil and resin of the myrrh in solution.

There are very few substances to which the mode of filtration by displacement will not be found applicable, if due attention be paid to the circumstances which require variations in the process.*

Pharmacopœias.

As the Pharmacopœias of the United States and Great Britain constitute the basis of the present work, there would seem to be an obvious propriety in devoting, in the present place, a few words to the explanation of their general character. Pharmacopœias are authoritative codes for the regulation of the Materia Medica and Pharmacy within the limits where their authority is admitted. Every fully civilized nation has one or more recognised Pharmacopœias. In most countries they are prepared under the authority more or less direct of the government, and have the sanction of law. In the United States the Pharmacopœia is the result of the voluntary action of the Professions of Medicine and Pharmacy, and has no other sanction than that of opinion. Nevertheless, within the limits of the two Professions referred to, it is probably quite as authoritative as though established by legal enactment. Works of this kind are necessarily compendious, as it is only by adhering to what is generally admitted to be essential, that they can expect to secure general acceptance. To give them full effect, explanations, comment, and various illustrations are necessary; and it is for this purpose that works called Dispensatories are written. Until recently there were three Pharmacopœias in the British Dominions, under the sanction respectively of the three Colleges of London, Edinburgh, and Dublin. This created much confusion in Great Britain, which in some degree extended also to the United States, where these works were at one time our only Pharmaceutical codes, and, in consequence of the general use of British works on medicine, continued to exert a considerable influence. By a very wise determination of the medical profession in Great Britain and Ireland, operating through the general Parliament, the three Pharmacopœias have been succeeded by a single one for the Empire, prepared under the direction of the Medical Council, which is at present the legal representative of the whole profession. It is this work, styled the British Pharmacopœia, that we comment upon in the present edition of the Dispensatory; the three former London, Edinburgh, and Dublin

* Much is due for the improvements which have added to the efficiency of percolation, as practised in the United States, to Prof. Grahame of Baltimore, Prof. Procter of Philadelphia, and Dr. Squibb of New York, whose several papers on the subject are published in the *Proceedings of the Am. Pharm. Assoc.* (A. D. 1858, p. 255), and in the *Am. Journ. of Pharm.* (March, 1858, p. 97, and July, 1859, p. 317).—*Note to the twelfth edition.*

Repercolation. This name has been given by Dr. Edward R. Squibb to a modification of the process of percolation, especially adapted to economy in the use of alcohol and other high priced fluids used as menstrua, which theory and experience unite in determining to be very important for the object aimed at. It consists essentially in the use of the same portion of percolating fluid with different portions successively of the substance percolated, so that the percolate becomes intensely concentrated, and not only is much of the menstruum saved, but much less evaporation is necessary in obtaining the extracted matter. There may be some waste in the medicine submitted to this process, as it is scarcely possible that it should be so thoroughly exhausted as it is in the ordinary process; but the loss in this direction is trifling when compared with the gain in that of a very costly menstruum. The subject will be more fully treated of under the head of *Extracts*, to the preparation of which repercolation is especially applicable. (*Note to the thirteenth edition.*)

Pharmacopœias having been superseded by it. The first British Pharmacopœia was published in 1864, but in various points proved so unsatisfactory to the medical and pharmaceutical professions that a revision was imperatively called for; and in 1867 a new and much altered edition was published, which is now the recognised standard.

The U. S. Pharmacopœia consists essentially of two parts, one called the Materia Medica, giving a list of the recognised medicines, with definitions sufficient to establish their identity and purity, and the other entitled Preparations or Preparations and Compounds, giving processes for the preparation of such medicines as may be supposed to be made by the apothecary. This was also the plan of all the old British Pharmacopœias, including the first edition of the work especially so designated, though with some modifications peculiar to itself; but the arrangement has been abandoned in the present British Pharmacopœia, which has, unwisely, we think, adopted a mere alphabetical succession of objects, like a dictionary or encyclopædia, placing in immediate contiguity medicines and preparations, without any other relation than the alphabetical succession of the initial letters of their names. This is a return to the practice of the earlier pharmacy, which experience taught to be inconvenient as well as unscientific, and in the adoption of which the present British Pharmacopœia stands almost if not entirely alone. Another change in the British Pharmacopœia is in the character of the nomenclature, which, in the first edition, was neat and simple, following for the most part that of the old London Pharmacopœia, and corresponding to a considerable extent with our own, which was framed with great care, and upon sound principles. Instead of giving medicines the simplest names, as Anthemis, Arnica, Buchu, Calumba, Cinchona, Senega, Serpentaria, &c., it has been thought advisable in very many instances to include in the title the part used, as Anthemidis Flores, Calumbæ Radix, Cinchonæ Cortex, thus returning to the old cumbrous nomenclature, out of which medicine and pharmacy have been gradually working their way, after a long struggle, into the present beautiful and convenient simplicity. Another point in which the U. S. Pharmacopœia has the advantage is the existence of a Secondary Catalogue, which may receive doubtful medicines, upon the value of which all cannot agree, and in which may be placed new medicines yet on trial but not generally adopted, and others going out of use, but still not without advocates in the profession. The British Materia Medica is somewhat more elaborate than ours in its descriptions, which is a doubtful merit, as the work is thus liable to come into unnecessary conflict with opinion, and thus to provoke contradiction. Besides the medicines and preparations, the British Pharmacopœia has an Appendix, containing a list of substances, with the modes of preparing them when necessary, used in testing the medicines employed; and, moreover, two other supplementary lists, one of substances used as ordinary tests in determining the character and purity of medicines, and the other of certain preparations employed in volumetric analysis, which we are disposed to consider as useful features of the work, and which will be given at the close of *Part* II. of the Dispensatory, so far as the individual articles may not be noticed elsewhere in the book

ACETA.

Vinegars.

Under this title, in the United States Pharmacopœia, are included both Distilled Vinegar, and those preparations usually denominated *Medicated Vinegars*. The latter are infusions or solutions of various medicinal substances in vinegar or acetic acid. The advantage of vinegar as a menstruum is that, in consequence of the acetic acid which it contains, it will dissolve substances not readily soluble, or altogether insoluble, in water alone. It is an excellent solvent of the organic alkalies, which it converts into acetates, thereby modifying, in some measure, though not injuriously, the action of the medicines of which they are

ingredients. As ordinary vinegar contains principles which promote its decomposition, it should be purified by distillation before being used as a solvent. Infusions prepared with it, even in this state, are apt to spoil in a short time; and a portion of alcohol is usually added to contribute to their preservation. A small quantity of acetic ether is said to result from this addition; and, on the continent of Europe, the place of the alcohol is frequently supplied by an equal amount of concentrated acetic acid. At present diluted acetic acid is generally preferred as the menstruum to distilled vinegar, as being of more uniform strength. In consequence of their liability to change, the medicated vinegars should be made in small quantities, and kept but for a short time. W.

ACETUM DESTILLATUM. *U. S. Distilled Vinegar.*

"Take of Vinegar *eight pints.* Distil, by means of a sand-bath, from a glass retort into a glass receiver, seven pints. Distilled Vinegar may be substituted for Diluted Acetic Acid in the preparation of the officinal vinegars." *U. S.*

Distilled vinegar, though formerly among the London and Edinburgh officinals, has been omitted in the Br. Pharmacopœia.

Vinegar is a very heterogeneous liquid, containing colouring matter, gum, sugar, alcohol, &c.; and the object of the distillation is to purify it. (See *Acetum.*) The first portion that distils contains alcohol, aldehyd, and pyroacetic spirit (acetone), these being the most volatile ingredients; next the acetic acid comes over much purified, but weaker than it exists in the vinegar, on account of its being less volatile than water; and, if the distillation be stopped when the pure vinegar ceases to come over, there will be found in the retort a liquid of a deep-brown colour, very sour and empyreumatic, and containing free tartaric and malic acids, bitartrate of potassa, and other substances. This statement explains why the last portion (one-eighth) is not distilled; the seven-eighths which first come over being alone preserved. The residuary liquid in the retort, if diluted with an equal bulk of hot water, may be made to yield, by a fresh distillation, a quantity of weak acetic acid equal to the residuary liquid, and of about the strength and purity of officinal distilled vinegar.

Wine vinegar furnishes a stronger and more aromatic distilled vinegar than malt or cider vinegar. The U. S. Pharmacopœia does not give the density, on account of its being an uncertain criterion of strength. The saturating power is the proper test of the acid present. This, according to the Pharmacopœia, is such that 100 grains of the Distilled Vinegar saturate not less than 7·6 grains of bicarbonate of potassa, so that it must have at least the strength of the officinal Diluted Acetic Acid. The saturating power, thus given, indicates 5 per cent. as the proportion of monohydrated acetic acid contained in it. Considering the ordinary pharmaceutical uses of distilled vinegar, variations in its strength, limited as they are by the qualities of different vinegars, are of no great consequence. Its purity is the point of importance. If, however, precision be attempted, the saturating power and not the density must be indicated; and directions should be given for bringing a distilled vinegar, which varies from the standard of saturating power, to that standard by the addition either of pure acetic acid or of distilled water. The reason why density cannot be depended upon, is that the specific gravity is not in proportion to the strength. If the vinegar contain a good deal of alcohol and pyroacetic spirit, the distilled product will be light, but not necessarily weak. This remark applies particularly to distilled wine vinegar.

The U. S. Pharmacopœia directs the distillation of vinegar to be conducted in glass vessels; but it is generally distilled in a copper alembic furnished with a pewter worm. The use of these metals, however, endangers metallic impregnation. Mr. Brande has suggested that the condenser might be made of very thin silver, a metal not acted on by acetic acid of any strength. If this cannot be procured, the head and worm should be of glass or earthenware. Empyreuma is effectually prevented by distilling by means of steam.

Properties. Distilled vinegar is a limpid, colourless liquid, of a weak acetous taste and smell, less agreeable than those of common vinegar. It is wholly volatilized by heat. It is not a perfectly pure solution of acetic acid in water; but

contains a small proportion of aldehyd, which rises in the distillation. It is on account of the partial decomposition of this impurity that distilled vinegar, when saturated with an alkali, is liable to become of a reddish or brownish colour. The Pharmacopœia, however, directs that it should not change colour upon the addition of ammonia. When distilled in metallic vessels, it is apt to contain traces of copper, lead, and tin. Copper is detected, after saturating with ammonia, by the addition of ferrocyanide of potassium, which produces a brown cloud; lead by iodide of potassium, which occasions a yellow precipitate; and tin by a solution of terchloride of gold, which causes a purplish appearance. The last two metals are discovered also by sulphuretted hydrogen, which occasions a dark-coloured precipitate. The non-action of this gas proves the absence of metals generally. Distilled vinegar should not have an empyreumatic taste or a sulphurous smell. As usually prepared, however, it is somewhat empyreumatic. British malt vinegar is allowed by law to contain one-thousandth of sulphuric acid; but, when it is distilled, this acid does not come over. If, however, sulphuric acid should be accidentally present in distilled vinegar, it may be detected by chloride of barium or acetate of lead. If muriatic acid be present, it may be shown by a precipitate being formed with nitrate of silver; and if nitric acid be an impurity, the vinegar will possess the property, by digestion, of dissolving silver, which may be detected afterwards by muriatic acid.

Medical Properties and Uses. The medical properties of distilled vinegar are the same as those of common vinegar (see *Acetum*); but the former, being purer, and not liable to spontaneous decomposition, is preferable for pharmaceutical purposes. Still, distilled vinegar is less pure than the officinal diluted acetic acid, which has been substituted for it in the preparations. B.

ACETUM CANTHARIDIS. *Br. Vinegar of Cantharides.*

"Take of Cantharides, in powder, *two ounces* [Avoirdupois]; Glacial Acetic Acid *two fluidounces* [Imperial measure]; Acetic Acid *eighteen fluidounces* [Imp. meas.], or *a sufficiency*. Mix thirteen fluidounces of the Acetic Acid with the Glacial Acetic Acid, and digest the Cantharides in this mixture for two hours at a temperature of 200°; then transfer the ingredients, after they have cooled, to a percolator, and, when the liquid ceases to pass, pour five fluidounces of Acetic Acid over the residuum in the apparatus. As soon as the percolation is complete, subject the contents of the percolator to pressure, filter the product, mix the liquids, and add sufficient Acid to make one pint [Imp. meas.]." *Br.*

This preparation was formerly officinal in all the Pharmacopœias of the British Islands; being recognised under its present title by the Edinburgh and Dublin Colleges, and under that of Acetum Cantharidis (Epispasticum) by the London; but it was omitted in the first British Pharmacopœia, to be resumed in the present. The mode of preparation differs mainly in the partial substitution of percolation for maceration and expression. The addition of the glacial to the officinal acetic acid is simply to increase the strength of the latter. The preparation is a little stronger than that of the late London Pharmacopœia, but weaker than the Edinburgh and Dublin.

This preparation is intended exclusively for external use, as a speedy epispastic. It is said, when lightly applied by a brush, to act as a rubefacient; and, when rubbed freely upon the skin for three minutes, to be followed, in two or three hours, by full vesication. The pain produced by the application, though more severe, is also more transient than that occasioned by the blistering cerate. From experiments made by Mr. Redwood, it may be inferred that the old Acetum Cantharidis of the London Pharmacopœia, which was prepared by maceration without heat, proved epispastic chiefly if not exclusively in consequence of its acetic acid, and that it contained little of the active principle of the flies. (*Lond. Pharm. Journ. and Trans.*, Oct. 1841.) Prof. Procter found that, by digestion at a temperature of 212° F., the active principle of the flies is readily taken up by officinal acetic acid, though a portion of the cantharidin is deposited upon cooling. (*Am. Journ. of Pharm.*, xxiv. 299.) It would seem, therefore,

that the vinegar of Spanish flies would be best prepared with the aid of heat; and, to a certain extent, this advantage is enjoyed in the present process. W.

ACETUM COLCHICI. *U.S. Vinegar of Colchicum.*

"Take of Colchicum Root, in fine powder, *two troyounces;* Diluted Acetic Acid *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Acetic Acid, allow it to stand for half an hour, pack it firmly in a conical glass percolator, and gradually pour upon it Diluted Acetic Acid until the filtered liquid measures two pints.

"Vinegar of Colchicum may also be prepared by macerating the Colchicum Root, in moderately fine powder, with two pints of Diluted Acetic Acid, in a close glass vessel, for seven days; then expressing the liquid, and filtering through paper." *U. S.*

Vinegar is an excellent solvent of the active principle of colchicum; and the organic alkali of the latter loses none of its efficacy by combination with the acetic acid of the former. Of the two formulas above given, the first, directing percolation, is much preferable to the second, permitting maceration, if performed by competent hands; and the same remark will apply to all the medicated vinegars in which an alternative formula is given.

Medical Uses. This preparation has been extolled as a diuretic in dropsy, and may be given in gout, rheumatism, and neuralgia; but the wines of colchicum are usually preferred. It is recommended by Scudamore to be given in connection with magnesia, so as to neutralize the acetic acid of the menstruum. The dose is from thirty drops to two fluidrachms. W.

ACETUM LOBELIÆ. *U.S. Vinegar of Lobelia.*

"Take of Lobelia, in moderately coarse powder, *four troyounces;* Diluted Acetic Acid *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour upon it Diluted Acetic Acid until the filtered liquid measures two pints

"Vinegar of Lobelia may also be prepared by macerating the powder in two pints of Diluted Acetic Acid for seven days, expressing the liquid, and filtering through paper." *U. S.*

This is a good preparation of lobelia, and might well be formed into a syrup, by the addition of sugar, as in the syrup of squill. It has the advantage that acetic acid gives stability to the alkaloid, which is very liable to decomposition, especially under the influence of heat. It may be used for all the purposes for which lobelia is given, either in substance or tincture; but is best adapted to cases in which the medicine is exhibited in small doses frequently repeated, with a view to its antispasmodic and expectorant action, as in asthma, spasmodic catarrh, and catarrhal croup, in which it may often be advantageously conjoined with the syrups of seneka and squill. For these purposes the dose for an adult is from thirty minims to a fluidrachm, repeated three or four times a day, or more frequently if required. In the paroxysm of spasmodic asthma one or two fluidrachms may be given every two or three hours till relief is obtained. The emetic dose would be half a fluidounce. W.

ACETUM OPII. *U.S. Vinegar of Opium. Black Drop.*

"Take of Opium, dried, and in moderately coarse powder, *five troyounces;* Nutmeg, in moderately coarse powder, *a troyounce;* Saffron, in moderately coarse powder, *one hundred and fifty grains;* Sugar *eight troyounces;* Diluted Acetic Acid *a sufficient quantity.* Macerate the Opium, Nutmeg, and Saffron with a pint of Diluted Acetic Acid for twenty-four hours. Put the mixture into a conical glass percolator, and return the liquid which first passes until the filtrate becomes clear. Then gradually pour on Diluted Acetic Acid until the filtered liquid measures twenty-six fluidounces. In this dissolve the Sugar, and, having strained the solution, add sufficient Diluted Acetic Acid to make the whole measure two pints." *U. S.*

The vinegar of opium was introduced into the Pharmacopœias as an imitation of or substitute for a preparation, which has been long in use under the

name of *Lancaster* or *Quaker's black drop*, or simply *black drop*. The formula of the first edition of the U. S. Pharmacopœia was so deficient in precision, and so uncertain in its results, that it was abandoned in the second edition; but, as these objections were obviated in a process by Mr. Charles Ellis, published in the *American Journal of Pharmacy* (vol. ii. page 202), and as the preparation continued to enjoy a considerable degree of professional and popular favour, it was deemed proper to restore it to its officinal rank at the subsequent revision of the Pharmacopœia. The U. S. formula above given is essentially that of Mr. Ellis, but with improvements which obviate the necessity of evaporation. The preparation has, we think unfortunately, been omitted in the British Pharmacopœia with most of the other vinegars. The advantages of the black drop over laudanum are, probably, that disturbing principles contained in opium and soluble in alcohol are left behind by the aqueous menstruum employed; while the meconate of morphia is converted by the acetic acid into the acetate. In the original process, published by Dr. Armstrong, who found it among the papers of a relative of the proprietor in England, *verjuice*, or the juice of the wild crab, was employed instead of vinegar. Other vegetable acids also favourably modify the narcotic operation of opium; and lemon-juice has been employed in a similar manner with vinegar or verjuice, and perhaps not less advantageously.*

The vinegar of opium may sometimes be advantageously used when opium itself, or the tincture, in consequence of peculiarity in the disease or in the constitution of the patient, occasions so much headache, nausea, or nervous disorder, as to render its employment inconvenient if not impossible. It exhibits all the anodyne and soporific properties of the narcotic, with less tendency to produce these disagreeable effects, at least in many instances. The U. S. preparation is of double the strength of laudanum, six and a half minims containing the soluble parts of about one grain of opium, supposing the drug to be completely exhausted by the menstruum. The dose may be stated at from seven to ten drops or minims. W.

ACETUM SANGUINARIÆ. *U. S. Vinegar of Bloodroot.*

"Take of Bloodroot, in moderately coarse powder, *four troyounces;* Diluted Acetic Acid *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour upon it Diluted Acetic Acid until the filtered liquid measures two pints.

"Vinegar of Bloodroot may also be prepared by macerating the powder with two pints of Diluted Acetic Acid for seven days, expressing the liquid, and filtering through paper." *U. S.*

This is one of the new officinals of the U. S. Pharmacopœia. It is no doubt an efficient preparation, and may be used for the same purposes as the powdered root. When first prepared, it has a deep-red colour, which is diminished by time; but through what chemical agency is unknown; as, according to Prof. Procter, the change is independent of the acetate of sanguinarina, which is formed in the process. (*Am. Journ. of Pharm.*, May, 1864, p. 210.) A syrup may be formed from this vinegar by the addition of sugar, as in the syrup of squill. The dose of the vinegar of bloodroot as an emetic is three or four fluidrachms; as an alterative and expectorant, from fifteen to thirty drops or minims It has been used as a local remedy in ringworm and other cutaneous diseases, and has been found by Dr. R. G. Jennings efficient as a gargle in the sorethroat of scarlet fever. W.

* The following is the formula given in the first edition of the U. S. Pharmacopœia. "Take of Opium *half a pound;* Vinegar *three pints;* Nutmeg, bruised, *one ounce and a half;* Saffron *half an ounce.* Boil them to a proper consistence; then add Sugar *four ounces;* Yeast *one fluidounce.* Digest for seven weeks, then place in the open air until it becomes a syrup; lastly, decant, filter, and bottle it up, adding a little sugar to each bottle." The boiling to a *proper consistence*, the digestion in the open air *until a syrup is formed*, and the addition of a *little sugar* to each bottle, are all indefinite directions which must have led to uncertain results. Independently of this want of precision, the point in which the old process chiefly differs from that at present officinal is, that, in the former, fermentation is induced by the addition of yeast. But fermentation is of very doubtful value in the process; at least its advantages have not been proved.

ACETUM SCILLÆ. *U. S., Br. Vinegar of Squill.*

"Take of Squill, in moderately coarse powder, *four troyounces;* Diluted Acetic Acid *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Acetic Acid, pack it in a conical glass percolator, and gradually pour upon it Diluted Acetic Acid until the filtered liquid measures two pints.

"Vinegar of Squill may also be prepared by macerating the Squill with two pints of Diluted Acetic Acid for seven days, expressing the liquid, and filtering through paper." *U. S.*

"Take of Squill, bruised, *two ounces and a half* [avoirdupois]; Diluted Acetic Acid *one pint* [Imperial measure]; Proof Spirit *one and a half fluidounce* [Imp. meas.]. Macerate the Squill in the Acetic Acid for seven days, then strain with expression, add the Spirit to the strained liquor, and filter." *Br.*

A practical error occurred, in the late revision of the U. S. Pharmacopœia, in the directions of its formula, which renders the whole process almost nugatory. Notwithstanding the coarseness of the powder as ordered, the disposition of squill to swell up and form an adhesive mass with the menstruum is such, that the percolation cannot be satisfactorily effected in strict compliance with the directions. The squill should be first mixed with a pint of the diluted acetic acid, as ordered in the Pharmacopœia of 1850, and, when the swelling has taken place, the whole mass should be transferred to a conical percolator of glass, and properly packed by means of agitation and gentle pressure, after which the process is to be completed, as directed in the formula, by adding the diluted acid gradually until two pints of the vinegar have passed. (Procter, *Am. Journ. of Pharm.*, July, 1864, p. 298.)

This was formerly an officinal of the Lond., Ed., and Dub. Colleges, but was omitted as a distinct preparation in the first British Pharmacopœia, being retained simply as the first step in the preparation of the syrup. It has, however, been introduced into the present edition. As vinegar of squill is apt to be injured by keeping, it should be prepared frequently, and in small quantities, as wanted for use. The spirit added to it in the British formula was intended to contribute to its preservation; but, in the quantity used, it is doubtful whether it would have any such effect. The Vinegar is employed chiefly in the preparation of the syrup of squill. Upon standing, it deposits a precipitate, consisting, according to Vogel, of citrate of lime and tannic acid.

Medical Uses. This preparation has all the properties of the squill in substance, and is occasionally prescribed as a diuretic and expectorant in various forms of dropsy and of pulmonary disease; but the syrup is usually preferred, as it keeps better, and is less unpleasant to the taste. The dose is from fifteen minims to a fluidrachm; but the latter quantity would be apt to nauseate. It should be given in cinnamon-water, mint-water, or other aromatic liquid calculated to conceal its taste and obviate nausea.*

Off. Prep. Oxymel Scillæ, *Br.;* Syrupus Scillæ. W.

* *Acidum Aceticum Camphoratum* (*Ed., Dub.*). *Camphorated Acetic Acid.* This is an old officinal of the Ed. and Dub. Pharmacopœias, which, though omitted in the British, deserves to be retained in a note, if only from its old reputation. It was prepared as follows.

"Take of Camphor *one ounce* [avoird.]; Rectified Spirit *one fluidrachm;* Strong Acetic Acid *ten fluidounces.* Reduce the camphor to powder by means of the Spirit; then add the Acid, and dissolve." *Dub.*

The use of the alcohol is simply to facilitate the pulverization of the camphor, and a few drops are sufficient. Acetic acid in its concentrated state readily dissolves camphor. In this preparation, the whole of the camphor is taken up by the acid. In consequence of the powerful chemical agency of the solution, and its extreme volatility, it should be kept in glass bottles accurately fitted with ground stoppers. Camphorated acetic acid is an exceedingly pungent perfume, which, when snuffed up the nostrils, produces a strongly excitant impression, and may be beneficially resorted to in cases of fainting or nervous debility. It was an officinal substitute for Henry's *aromatic spirit of vinegar.*

At Apothecaries' Hall, in London, an *aromatic vinegar* is prepared by dissolving the oils of cloves, lavender, rosemary, and calamus, in highly concentrated acetic acid. It is used for the same purpose as the officinal camphorated acetic acid, being dropped on sponge, and kept in smelling-bottles. A similar preparation may be made extemporaneously by

ACIDA.

Acids.

Acids are compounds which are capable of uniting in definite proportions with alkalies, earths, and ordinary metallic oxides, with the effect of producing a combination, in which the properties of its constituents are mutually destroyed. Such combinations are said to be neutral, and are denominated salts. Most acids have a sour taste, and possess the power of changing vegetable blues to red; and, though these properties are by no means constant, yet they afford a convenient means of detecting acids, applicable in practice to most cases. The above explanation of the nature of an acid is that usually given; but, according to strict definition, acids are compounds having a strong electro-negative energy, and, therefore, possessing a powerful affinity for electro-positive compounds, such as alkalies, earths, and ordinary oxides. It is this antagonism in the electrical condition of these two great classes of chemical compounds that gives rise to their mutual affinity, which is so much the stronger as the contrast in this respect is greater. In the majority of cases, the electro-negative compound or acid is an oxidized body, but by no means necessarily so. When an acid does not contain oxygen, hydrogen is usually present. These peculiarities in composition have given rise to the division of acids by some writers into *oxacids* and *hydracids*. *Vegetable acids*, for the most part, contain both hydrogen and oxygen.

The number of acids used in medicine is small; but among these are to be found examples of the three kinds above mentioned. B.

ACIDUM ACETICUM DILUTUM. *U. S.*, *Br.* *Diluted Acetic Acid.*

"Take of Acetic Acid *a pint;* Distilled Water *seven pints.* Mix them." The sp. gr. of this acid is 1·006, and 100 grains of it saturate 7·6 grains of crystallized bicarbonate of potassa. *U. S.*

"Take of Acetic Acid *one pint* [Imperial measure]; Distilled Water *seven pints* [Imp. meas.]. Mix." *Br.* The sp. gr. of this acid is 1·006, and an Imperial fluidounce of it (440 grains by weight) requires for neutralization 313 grain-measures of the *volumetric solution of soda*, corresponding to 3·63 per cent. of anhydrous acetic acid. One Imperial fluidounce, therefore, corresponds to 16 grains of anhydrous acid. *Br.*

The object of having this preparation is to possess a weak solution of *pure* acetic acid, which may be substituted for distilled vinegar in all formulas in which nicety is required. Distilled vinegar contains a little organic matter, which is always darkened or precipitated when its acid is saturated with an alkali, an occurrence which does not take place when the diluted acetic acid is employed. The saturating strength of the diluted acid of the U. S. Pharmacopœia indicates the same proportion of monohydrated acetic acid as is contained in the officinal distilled vinegar, namely, 5 per cent. The British diluted acid has the same sp. gr. as our own, viz. 1·006.

adding to a drachm of acetate of potassa, contained in a stoppered bottle, three drops of one or more of the aromatic volatile oils, and twenty drops of sulphuric acid. (*Pereira.*)

A preparation called *Marseilles vinegar*, or *thieves' vinegar* (*vinaigre des quatre voleurs*), consisting essentially of vinegar impregnated with aromatic substances, was formerly esteemed a prophylactic against the plague and other contagious diseases. It is said to have derived its name and reputation from the circumstance, that four thieves, who, during the plague at Marseilles, had plundered the dead bodies with impunity, confessed, upon the condition of a pardon, that they owed their safety to the use of it. The *aromatic acetic acid* of the former Edinburgh Pharmacopœia was intended as a simplification of this nostrum. It was made by macerating for a week an ounce of rosemary, an ounce of sage, half an ounce of lavender, and half a drachm of cloves, with two pounds of distilled vinegar, then expressing the liquor and filtering. Origanum was afterwards substituted for sage, and thirty fluidounces of acetic acid for two pounds of distilled vinegar. In the last edition of the Pharmacopœia the preparation was abandoned. In the present state of knowledge, it is hardly necessary to observe that neither the original nostrum, nor its substitute, has any other power of protecting the system against disease than such as may depend on its slightly stimulant properties, and its influence over the imagination. W.

In making this preparation, whenever the apothecary is doubtful as to the strength of the acetic acid he employs, it will be his duty to ascertain its saturating power, and, if this should vary from the standard, to vary the dilution accordingly.

Diluted acetic acid has been employed with advantage in scarlatina by Dr. I. B. Brown, of London, who published a treatise on its use in 1846. Dr. B. F. Schneck, of Lebanon, Pa., has imitated this practice, and with good results. (*Am Journ. of Med. Sci.*, July, 1857, p. 27.)

ACIDUM BENZOICUM. *U. S.*, *Br.* *Benzoic Acid.*

"Take of Benzoin, in coarse powder, *twelve troyounces*. Spread the Benzoin evenly over the bottom of an iron dish eight inches in diameter, cover the dish with a piece of filtering paper, and, by means of paste, attach it closely to the rim. Then, having prepared a conical receiver or cap of thick, well-sized paper, of rather larger diameter than the dish, invert it over the latter, so as to fit closely around the rim. Next apply heat by means of a sand-bath, or of the iron plate of a stove, until, without much empyreuma, vapours of Benzoic Acid cease to rise. Lastly, separate the receiver from time to time, and remove the Benzoic Acid from it and the paper diaphragm, as long as the Acid continues to be deposited." *U. S.*

The British Pharmacopœia has omitted its process for the preparation of benzoic acid, and defines it to be "a crystalline acid obtained from benzoin, and prepared by sublimation."

The Pharmacopœias now unite in the preparation of benzoic acid by sublimation. Formerly the benzoin was mixed with an equal weight of sand; but this has been omitted, as not only useless, but probably injurious by favouring the production of empyreumatic substances. The acid, which exists in the benzoin combined with resin, is volatilized by the heat, and condensed in the upper part of the apparatus. Unless the temperature is very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid, and gives it a brown colour, from which it cannot be entirely freed by bibulous paper; and this result sometimes takes place even with the greatest caution. The process for subliming benzoic acid may be conducted in a glazed earthen vessel, surmounted by a cone of paper, or by another vessel with a small opening at the top, and a band of paper pasted round the place of junction. After the heat has been applied for an hour, the process should be suspended till the condensed acid is removed from the upper vessel or paper cone, when it may be renewed, and the acid again removed, and thus alternately till coloured vapours rise. Mohr, after many experiments, recommends the following plan as unobjectionable. In a round cast-iron vessel, eight or nine inches in diameter and two inches deep, a pound or less of coarsely powdered benzoin is placed, and uniformly strewed over the bottom. The top of the vessel is closed by a sheet of bibulous paper, which is secured to the sides by paste. A cylinder of thick paper in the form of a hat, just large enough to fit closely around the sides of the pot, is then placed over it, and in like manner secured by paste. A moderate heat is now applied by means of a sand-bath, and continued for three or four hours. The vapours pass through the bibulous paper, which absorbs the empyreumatic oil, and are condensed within the hat in brilliant white flowers, having an agreeable odour of benzoin. (*Annal. der Pharm.*, xxix. 178.) After a time the bibulous paper becomes so saturated with empyreumatic products as no longer to arrest them, and should then be replaced with a fresh piece. (*Maisch.*) The remaining acid of the benzoin may be extracted, if deemed advisable, by treating the residue of the balsam with lime or carbonate of soda. The process of Mohr has been adopted in the present edition of the U. S. Pharmacopœia, and is probably preferable to any method heretofore proposed. From

the mode of preparing benzoic acid by sublimation, it was formerly called *flowers of benzoin.*

Another mode of separating the acid from benzoin is by combining it with a salifiable base, and precipitating with an acid. Such is the process of Scheele. It consists in boiling the powdered benzoin with hydrate of lime and water, filtering the solution of benzoate of lime thus obtained, and precipitating the benzoic acid with muriatic acid. Carbonate of soda or of potassa may be substituted for the lime, and sulphuric for the muriatic acid; and the precipitated benzoic acid may be purified by dissolving it in boiling water, which will deposit it upon cooling. The acid, however, requires to be still further purified by repeated crystallization from small portions of boiling water. A little animal charcoal may be employed to render the crystals quite colourless. These processes afford a purer product than that obtained by sublimation, but not preferable in a medicinal point of view; as the small quantity of oil present in the sublimed acid adds to its stimulant properties, and at the same time renders it pleasant to the smell. In order to get the benzoic acid in the form to which the eye is accustomed, it has been proposed to sublime the acid after its precipitation.

Several other modes of extracting the acid have been recommended. The following is the process of Stolze. One part of the balsam is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by carbonate of soda dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off; and the benzoate of soda contained in the residuary liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which lets fall the acid when it cools. By this process Stolze obtained 18 per cent. of acid from benzoin containing 19·425 per cent. By the process of Scheele he obtained 13·5 per cent.; by the agency of carbonate of soda, 12 per cent.; by sublimation only 7·6 per cent. Nevertheless, Mr. Brande says that the last process is on the whole the most economical. According to this author, good benzoin affords by sublimation from 10 to 15 per cent. of the acid contaminated with empyreumatic oil, and about 9 per cent. of the purified acid. Professor Scharling has prepared benzoic acid by means of heated steam, and obtained 8 per cent. (*Am. Journ. of Pharm.*, xxiv. 236.)

The acid is said to be obtained very cheaply from *naphthalin* by a new process. We have seen no precise account of the method employed, but are informed that it is very extensively carried out by M. Castheluz in Paris. The *naphthalin* ($C_{20}H_8$) is first transformed into a bichloride (quadrichloride $C_{20}H_8 2Cl_2$), and this by oxidation into *phtalic* acid ($C_{16}H_4O_6 2HO$), which is combined with ammonia to form the phtalate ($C_{16}H_4O_6 2NH_3$). This by distillation furnishes *phtalamid* ($C_{16}H_5NO_4$), which by distillation with three parts of hydrate of lime yields *benzonitril* ($C_{14}H_5N$); and the latter, boiled with a solution of caustic soda, becomes benzoate of soda, from which benzoic acid is precipitated by muriatic acid. (*Chem. News*, Dec. 13, 1867, p. 296.)

A considerable quantity of benzoic acid has, within a few years, been imported into the United States from Germany, said to have been prepared from the urine of cattle and horses. It is white, has a fine lustre, and is said to be very pure, but sometimes has a slight urinous odour indicative of its origin. (*Am. Journ. of Pharm.*, xxvii. 23.) We are informed that it is now very largely made in Paris out of the same material.

Properties. Sublimed benzoic acid is in white, soft, feathery crystals, of a silky lustre, and not pulverulent. From solution the acid crystallizes in transparent prisms. When quite pure it is inodorous; but, prepared by sublimation from the balsam, it has a peculiar, agreeable, aromatic odour, dependent on the presence of an oil, which may be separated by dissolving the acid in alcohol, and precipitating it with water. Its taste is warm, acrid, and acidulous. It is unalterable in the air, but at 250° melts, and at a somewhat higher temperature rises in suffocating vapours. The Br. Pharmacopœia gives as its melting point 248°, and boiling point 462°. It is inflammable, burning without residue.

It is soluble in 200 parts of cold water (*Annals of Pharmacy*, i. 206), and in about 24 parts of boiling water, which deposits it upon cooling. The addition of borax increases its solubility. It is readily dissolved by alcohol, and by concentrated sulphuric and nitric acids, from which it is precipitated by water. The fixed oils also dissolve it. It is entirely soluble in solutions of potassa, soda, ammonia, and lime, from which it is precipitated by muriatic acid. Its solution reddens litmus paper, and it forms salts with salifiable bases; but its acid properties are not powerful. Benzoic acid consists of *benzyl* and oxygen, and in the uncombined state usually contains water. The anhydrous acid has, however, been isolated by Gerhardt. (*Chem. Gaz.*, x. 237.) Benzyl consists of fourteen eqs. of carbon 84, five of hydrogen 5, and two of oxygen 16 = 105. The crystallized acid contains one eq. of benzyl 105, one of oxygen 8, and one of water 9 = 122, the formula being $C_{14}H_5O_3,HO$. It cannot be deprived of its water by heat, but sometimes loses it in combination. Benzoic acid is a characteristic constituent of the balsams, and has been found in various other vegetable, and some animal products.* When heated it should sublime without residue; but the Br. Pharmacopœia allows a slight residue for impurities.

Medical Properties and Uses. Benzoic acid is irritant to the alimentary mucous membrane, and stimulant to the system, and has been thought to be expectorant; but it is not much used internally, except as a constituent of one or two officinal preparations. It was proposed by Dr. Alexander Ure as a remedy for uric acid deposits in the urine, and for the chalk-like concretions, consisting of urate of soda, in the joints of gouty individuals. He supposed it to operate by converting the uric into hippuric acid, and consequently the insoluble urates into soluble hippurates. It appears, however, from the observations of Dr. Garrod and Mr. Keller, that such a transformation of uric acid does not take place, but that the benzoic acid is itself converted into hippuric acid, which is always found in the urine, when the former acid is taken freely. The quantity of uric acid in the urine remains undiminished. But it has been shown by Kletzinsky that, though the uric acid is unaffected, the urea is decidedly diminished; and the quantity of nitrogen contained in the urea lost is almost exactly represented by the nitrogen of the hippuric acid formed; so that the benzoic acid is probably converted into the hippuric by combination with a nitrogenous body, either derived from the urea or formed at the expense of it. (*Ann. de Thérap.*, 1860, p. 110.) In consequence of the acid state of urine produced by benzoic acid, it has been found useful in the phosphatic variety of gravel; though its beneficial influence, being purely chemical, continues only during its use. It is said to have cured nocturnal incontinence of urine. Mr. White Cooper has employed it with supposed advantage in a case of rheumatic sclerotitis. (See *Am. Journ. of Med. Sci.*, N. S., xxv. 518.) A convenient mode of exhibition is to give the acid with four parts of phosphate of soda, or one part and a half of biborate of soda, which enables it to be readily dissolved by water. The dose is from 10 to 30 grains. It is an ingredient in some cosmetic washes, and has been employed by way of fumigation as a remedy in affections of the skin. It has also been employed as a local hæmostatic, in connection with alum, with considerable asserted success; but there can be little doubt that alum is the more efficient ingredient.

Off. Prep. Ammoniæ Benzoas, *Br.;* Tinctura Camphoræ Composita, *Br.;* Tinct. Opii Ammoniata, *Br.;* Tinct. Opii Camphorata, *U. S.* W.

ACIDUM GALLICUM. *U. S., Br. Gallic Acid.*

"Take of Nutgall, in fine powder, *thirty-six troyounces;* Purified Animal Charcoal, Distilled Water, each, *a sufficient quantity.* Mix the Nutgall with sufficient Distilled Water to form a thin paste, and expose the mixture to the air, in a shallow glass or porcelain vessel, in a warm place, for a month, occasionally stirring

* *Benzyl*, which was at first hypothetical, has been isolated. When benzoate of copper is cautiously distilled without water, it yields a product which crystallizes on cooling. This substance has the smell of geranium, melts at 158° F., and has a composition represented by the formula $C_{14}H_5O_2$. When heated with hydrate of potassa, it is converted into benzoic acid, with the escape of hydrogen. It is, therefore, benzyl. It was discovered by Etting, and afterwards investigated by Stenhouse. (*Fownes's Chemistry*, Am. ed., 1858, p. 401.)

it with a glass rod, and adding from time to time sufficient Distilled Water to preserve the semi-fluid consistence. Then submit the paste to expression, and, rejecting the expressed liquor, boil the residue in eight pints of Distilled Water for a few minutes, and filter while hot through Purified Animal Charcoal. Set the liquid aside that crystals may form, and dry them on bibulous paper. If the crystals be not sufficiently free from colour, they may be purified by dissolving them in boiling Distilled Water, filtering through a fresh portion of Purified Animal Charcoal, and crystallizing." *U. S.*

The *Dublin College* gave two processes, of which the first has been retained, with a few verbal modifications, in the British Pharmacopœia. It is essentially the same as the U. S. process; differing in requiring an exposure of six weeks instead of a month, in not expressing the paste before boiling in water, in expressing the impure acid deposited from the filtered decoction before redissolving it in boiling water, and in omitting the use of animal charcoal. The second process of the Dublin College, based on the influence of sulphuric acid in favouring the change of tannic into gallic acid, has the merit of requiring less time for completion. Notwithstanding its rejection in the late revision of the British Pharmacopœia, we retain it in the form of a note.*

The U. S. process is founded upon the fact that, when galls in infusion, or in the state of moistened powder, are exposed to the air, their tannic acid is gradually converted into gallic acid, with the absorption, as has been generally believed, of oxygen, and the escape of an equivalent quantity of carbonic acid. The gallic acid, being freely soluble in boiling but very sparingly in cold water, is extracted from the altered galls by decoction, and is deposited as the water cools. A repetition of the solution and deposition renders the acid more pure; but it cannot be obtained wholly colourless unless by the aid of animal charcoal. In the U. S. Pharmacopœia of 1850 it was neglected to direct *purified* animal charcoal; an inadvertence which has been corrected in the present edition. There are few processes in which it is more necessary that this decolorizing agent should be purified. The presence of the slightest quantity of sesquioxide of iron interferes with the bleaching of the acid; and it is even advisable to examine the filtering paper, lest it may contain sufficient of this substance to vitiate the results of the process. The first crop of crystals in the U. S. process retains a very large proportion of water; and it will be found convenient to subject them to strong expression between folds of bibulous paper.

Dr. C. Wetherill, believing that gallic acid differs from the tannic simply in containing water, conceived the idea of preparing the former from the latter by the fixation of water. This he effected through the agency of sulphuric acid. Having mixed 13 drachms of tannic acid with 22 fluidounces of sulphuric acid

* *Process by Sulphuric Acid.* "Take of powdered Galls *one pound* [avoirdupois]; Oil of Vitriol of Commerce *twenty-six fluidounces;* Water *five pints and fourteen* [*fluid*]*ounces* [Imp. meas.]. Steep the galls for twenty-four hours in one part of the water, then transfer them to a glass or porcelain percolator, and pour on a pint and a half of the water in successive portions. Dilute five ounces of the oil of vitriol with an equal bulk of water, and, when the mixture has cooled, add it to the infusion obtained by percolation, stirring well, so as to bring them into perfect contact. Let the viscid precipitate which forms be separated by a filter, and to the solution which passes through add five ounces more of the oil of vitriol, which will yield an additional precipitate. This being added to that previously obtained, let both be enveloped in calico, and subjected to powerful pressure. Dissolve the residue in the rest of the oil of vitriol, this latter being first diluted with what remains of the water; boil the solution for twenty minutes, then allow it to cool, and set it by for a week. Let the deposit which has formed at the end of this period be pressed, dried, and then dissolved in three times its weight of boiling water, clearing the solution, if necessary, by filtration, and, when it has cooled down to 80°, decant the liquid from the crystalline sediment which has formed, and wash the latter with three ounces of ice-cold water. Finally, let it be transferred to blotting paper, and, when deprived by this of adhering liquid, let it be dried perfectly at a temperature not exceeding 212°. The gallic acid obtained may be rendered nearly white by dissolving it in twenty times its weight of boiling distilled water, and causing the solution to traverse a stratum of prepared animal charcoal spread upon a calico filter. When the liquid passes through colourless it should be evaporated to one-sixth of its volume, and then suffered to cool in order to the separation of the crystallized acid." (*Dub.* A. D. 1850.)

and four times that bulk of water, he heated the mixture to the boiling point, and then allowed it to stand. In a few days an abundant precipitate of white gallic acid took place, amounting to 87·4 per cent. of the tannic acid. (*Am. Journ. of Pharm.*, xx. 112.) Upon the same principle is based the second process of the Dublin College above referred to. Dr. Christison, in his Dispensatory, states that the process was originally suggested by Liebig. It is now understood that tannic acid is a glucoside, convertible through exposure of galls to the air, and more rapidly by sulphuric acid, into glucose and gallic acid; and thus to a certain extent is explained the rationale of both the processes here noticed.

The elder Robiquet first suggested that galls contain a principle capable of converting tannic into gallic acid, with the presence of water, and in the absence of atmospheric air. M. Larocque proved that this principle acts as a ferment, and that the change referred to is the result of a *gallic acid fermentation* in the galls. M. Edmond Robiquet has shown that galls contain *pectose* and *pectase*, the former of which, according to the experiments of M. Frémy, is the principle out of which pectin is formed in plants, and the latter a peculiar ferment which effects the transformation. It appears that in galls the pectase, aided by a proper temperature and the presence of water, changes not only pectose into pectin, but also tannic into gallic acid. Strecker had previously advanced the opinion that tannic acid is a combination of gallic acid and sugar, the latter of which is destroyed in the process for procuring gallic acid, which is thus simply set free from the combination. It would seem, if this view is correct, that the pectase acts upon the saccharine matter of the tannic acid, causing its conversion into carbonic acid and alcohol, and liberating the gallic acid, and that the process is in fact an example of the vinous fermentation. M. E. Robiquet admits the occasional transformation of tannic acid into gallic acid and sugar, but does not believe that the sugar pre-exists as such in the tannin. (*Journ. de Pharm.*, 3e sér., xxiii. 241.) Wittstein, in endeavouring to obtain gallic acid from *Chinese galls* (see *page* 415) by forming them into a paste with water, found that but a very small proportion of the acid was generated at the end of six weeks. Thinking that this might have resulted from the want of the ferment in the Chinese galls, he added to these one-eighth of their weight of common galls, and, at the end of three weeks, obtained an amount of gallic acid nearly equal to one-half the weight of the galls employed. The same result, though more slowly, followed the addition of yeast to the Chinese galls. Wittstein obtained both carbonic acid and alcohol as products of this operation, thus favouring the views of Strecker as to the constitution of tannic acid.

Properties. Gallic acid is in delicate, silky, acicular crystals, which, as ordinarily found in the shops, are slightly brownish, but when quite pure are colourless. It is inodorous, and of a sourish, astringent taste. It is soluble, according to Braconnot, in 100 parts of cold and 3 of boiling water, is very soluble in alcohol, and but slightly so in ether. Mr. Thomas Weaver, of Philadelphia, has found that it is soluble in glycerin in the proportion of 40 grains to the ounce, and that the solution may be diluted to any extent with water without affecting its transparency. (*Am. Journ. of Pharm.*, xxix. 82.) It reddens litmus, and produces a deep bluish-black colour with solutions of the salts of sesquioxide of iron, which disappears when the solution is heated; a result which Dr. Mahla has shown to depend on the conversion of the gallic into gallhumic or metagallic acid, by the loss of the constituents of carbonic acid and water. (*Am Journ. of Sci. and Arts*, Nov. 1859.) It does not precipitate gelatin, or a solution of sulphate of protoxide of iron. It should leave no residue when burnt, and is entirely dissipated when thrown on red-hot iron. On exposure to the air, its solution undergoes spontaneous decomposition; but it is said that, by the addition of a drop of oil of cloves, it may be kept for a long time without change. (*Pharm. Journ.*, xvi. 223.) T. Löwe has found that gallic acid, dissolved in water, is converted into tannic acid by nitrate of silver through its oxidizing influence; and that the change is more complete when a salt of gallic acid is used. (*Chem. News*, Jan. 31, 1868, p. 59; from *Journ. für pract. Chem.*, cii. 111.) The form-

ula of gallic acid is $C_{14}H_6O_{10}$ (*Gmelin*). Heated to 420° it gives out carbonic acid, and is changed into *pyrogallic acid.* (See *Part* III.)

Medical Properties. Forming an ingredient in all astringent products containing gallo-tannic acid, gallic acid was at one time supposed to be the active principle of the vegetable astringents. This reputation it afterwards lost when the properties of tannic acid became well known. But it has recently again come into notice, and is now thought by many to be a very valuable astringent, having the property of arresting hemorrhages when taken internally, especially those from the uterus and urinary passages. In all cases of hemorrhage in which the bleeding vessels must be reached through the route of the circulation, it is believed by some to be more efficient even than tannic acid, as its chemical affinities do not afford the same impediment to its absorption as those of the latter acid. But in hemorrhage from the alimentary mucous membrane, or from any other part with which tannic acid can be brought into direct contact, the latter astringent is by far the most effectual. Gallic acid has been employed also with advantage in pyrosis, and the night-sweats of phthisis. It is said not to constipate the bowels. The dose is from five to fifteen grains three or four times a day, and may be given in the form of pill or powder. The acid has been employed as a gargle in inflammatory affections of the fauces. The comparative facility with which it is dissolved by glycerin, and the readiness with which the solution mixes with water, suggest the use of this menstruum when it may be desirable to employ the medicine locally as a gargle or injection.

ACIDUM HYDRIODICUM DILUTUM. *U.S.* *Diluted Hydriodic Acid.*

"Take of Iodine, in fine powder, *a troyounce;* Distilled Water *a sufficient quantity.* Mix thirty grains of the Iodine with five fluidounces of Distilled Water in a tall glass-stoppered bottle, having the capacity of half a pint, and pass into the mixture hydrosulphuric acid gas until the colour of the Iodine entirely disappears, and a turbid liquid remains. Detach the bottle from the apparatus employed for introducing the gas, and gradually add the remainder of the Iodine, stirring at the same time. Then reattach the bottle, and again pass the gas until the liquid becomes colourless. Decant the liquid into a small matrass which it is nearly sufficient to fill, boil it until it ceases to emit the odour of hydrosulphuric acid, and filter through paper. Then pass sufficient Distilled Water through the filter to bring the filtered liquid to the measure of six fluidounces. Lastly, keep the liquid in a well-stopped bottle.

"The hydrosulphuric acid gas, required in this process, may be obtained by mixing, in a suitable apparatus, *a troyounce and a half* of sulphuret of iron, *two troyounces* of sulphuric acid, and *six fluidounces* of water." *U. S.*

This preparation was introduced into the U. S. Pharmacopœia at its recent revision. The process consists essentially in passing hydrosulphuric acid (sulphuretted hydrogen) through water in which iodine is suspended. The rationale is extremely simple. The operation takes place between single equivalents of the several elements concerned. One eq. of the hydrogen of the hydrosulphuric acid unites with one of iodine to form hydriodic acid (HI), while the eq. of sulphur with which it was combined is isolated, and, being insoluble, renders the liquid turbid. The iodine is known to have been all combined by the disappearance of the colour. An excess of hydrosulphuric acid is of no disservice, as it is driven off by the boiling. By filtration the liberated sulphur is separated, and the clear diluted hydriodic acid remains. By taking fixed proportions of iodine and water, an acid of the desired strength is secured.

In its pure state hydriodic acid is in the form of a gas, which fumes in the air, is colourless, and has an odour not unlike that of hydrochloric acid. It has a strong affinity for water, which, when saturated with it, forms liquid hydriodic acid. This has the sp. gr. 1·7, boils at 260° F., and may be distilled. It is officinal only in the dilute state.

The diluted acid, as prepared by the U. S. process, is colourless when recently prepared, of a sour taste, and of the sp. gr. 1·112. When exposed to the air it gradually darkens, in consequence of the separation of iodine, of which it acquires the characteristic odour. It is more rapidly decomposed, with the same result, by chlorine, by nitric, sulphuric, iodic, and sulphurous acids, and by protosulphate of iron. Mr. John A. Dunn has found that this change is prevented by the addition of one-third of a grain of crystallized hyposulphite of soda to a fluidounce. (*Am. Journ. of Pharm.*, Jan. 1869, p. 42.)

Diluted hydriodic acid was introduced into use as a medicine by Dr. Andrew Buchanan, of Glasgow, under the impression, that it is by passing into this form that iodine, when taken internally, is absorbed, and enters the circulation. He believed it capable of producing all the effects of that element on the system, while it is less unpleasant to the taste, and less apt to offend the stomach. Dr. Buchanan used an extemporaneous formula, which consisted in dissolving 330 grains of iodide of potassium and 264 of tartaric acid, each in one and a half fluidounces of water, mixing the solutions, filtering to separate the bitartrate of potassa formed, and finally adding sufficient distilled water to make the solution measure fifty fluidrachms. Each fluidrachm of this preparation contained five grains of iodine. Beginning with a few drops, he gradually increased to a fluidrachm, and finally even half a fluidounce or a fluidounce three times a day.* The officinal acid contains ten grains of iodine in each fluidrachm, and is therefore twice as strong as Dr. Buchanan's solution. There can be little doubt that hydriodic acid is capable of producing the alterative effects of iodine; and it may be given in all cases to which that medicine is applicable. The dose may be half a fluidrachm three times a day, diluted with water. When the solution becomes discoloured it may be irritant through the liberated iodine; but this effect may be obviated by exhibiting it in any amylaceous liquid, as barley-water. W.

ACIDUM HYDROCYANICUM DILUTUM. *U. S.*, *Br.* *Diluted Hydrocyanic Acid. Prussic Acid. Cyanohydric Acid.*

"Take of Ferrocyanide of Potassium *two troyounces;* Sulphuric Acid *a troyounce and a half;* Distilled Water *a sufficient quantity.* Mix the Acid with four fluidounces of Distilled Water, and pour the mixture, when cool, into a glass retort. To this add the Ferrocyanide of Potassium, dissolved in ten fluidounces of Distilled Water. Pour eight fluidounces of Distilled Water into a cooled receiver, and, having attached this to the retort, distil, by means of a sand-bath, with a moderate heat, six fluidounces. Lastly, add to the product five fluidounces of Distilled Water, or as much as may be sufficient to render the Diluted Hydrocyanic Acid of such a strength, that 12·7 grains of nitrate of silver, dissolved in distilled water, may be accurately saturated by 100 grains of the acid.

"Diluted Hydrocyanic Acid, when wanted for immediate use, may be prepared in the following manner.

"Take of Cyanide of Silver *fifty grains and a half;* Muriatic Acid *forty-one grains;* Distilled Water *a fluidounce.* Mix the Muriatic Acid with the Distilled Water, add the Cyanide of Silver, and shake the whole together in a well-stopped vial. When the precipitate formed has subsided, pour off the clear liquid, and keep it for use. Diluted Hydrocyanic Acid must be kept in well-stopped bottles protected from the light." *U. S.*

"Take of yellow Prussiate of Potash *two ounces and a quarter* [avoirdupois]; Sulphuric Acid *one fluidounce* [Imperial measure]; Distilled Water

* Mr. John A. Dunn, of Brooklyn, proposes the following modification of Dr. Buchanan's process, for which he claims the advantage that the preparation is much less disposed to deposit bitartrate of potassa on standing, while it has the officinal strength. Take of Iodide of Potassium 209¾ grains; Tartaric Acid, in crystals, 190¼ grains. Dissolve the Iodide in three fluidrachms of distilled water, and the Acid in the same quantity, and filter if necessary; mix the solutions, set the mixture in ice-cold water, and allow it to stand for one hour; then filter, and make up the measure to two fluidounces. Each fluidrachm represents 10 grains of iodine. (*Am. Journ. of Pharm.*, Jan. 1869, p. 41.)—*Note to the thirteenth edition.*

thirty fluidounces [Imp. meas.], or *a sufficiency*. Dissolve the Prussiate of Potash in ten [fluid]ounces of the Water, then add the Sulphuric Acid previously diluted with four [fluid]ounces of the Water and cooled. Put the solution into a flask or other suitable apparatus of glass or earthenware, to which are adapted a condenser and a receiver arranged for distillation, and having put eight [fluid] ounces of Distilled Water into the receiver, and provided efficient means for keeping the condenser and receiver cold, apply heat to the flask until by slow distillation the liquid in the receiver is increased to seventeen [fluid]ounces. Add to this three [fluid]ounces of the Distilled Water, or as much as may be sufficient to bring the acid to the required strength, so that one hundred grains (or 110 minims) of it, precipitated with a solution of nitrate of silver, shall yield ten grains of dry cyanide of silver." *Br.*

The British preparation has the sp. gr. 0·997. If 270 grains of it be made alkaline by solution of soda, they will require 1000 grain-measures of the *volumetric solution of nitrate of silver* to be added before a permanent precipitate begins to form, corresponding to 2 per cent. of the real acid.

Hydrocyanic acid was admitted into the French Codex in 1818, into the United States Pharmacopœia in 1820, into the Dublin in 1826, into the London in 1836, and into the Edinburgh in 1839. It is now made by one chief process; namely, from the ferrocyanide of potassium by the action of sulphuric acid. It is also obtained by an extemporaneous process, in the U. S. Pharmacopœia, by decomposing cyanide of silver. When ferrocyanide of potassium is decomposed by sulphuric acid, the residue in the retort is sulphate of potassa, mixed with an insoluble compound of two eqs. of cyanide of iron, and one of cyanide of potassium (*Everitt's salt*). According to Wittstein, the reaction takes place in two steps. In the first, three eqs. of ferrocyanide $3(FeCy + 2KCy)$ react with six eqs. of hydrated sulphuric acid $6(HO,SO_3)$, and produce six eqs. of sulphate of potassa $6(KO,SO_3)$, and three eqs. of hydroferrocyanic acid $3(FeCy + 2HCy)$. In the second step, when heat is applied, the three eqs. of hydroferrocyanic acid $3(FeCy + 2HCy)$ react with an additional eq. of ferrocyanide $(FeCy + 2KCy)$, so as to produce six eqs. of hydrocyanic acid, 6HCy, which distil over, and two eqs. of Everitt's salt $2(2FeCy + KCy)$, which remain in the retort with the sulphate of potassa. (*Pharm. Journ.*, March, 1856, p. 429.) Everitt's salt, so named from its discoverer, is a yellowish-white powder. Like ferrocyanide of potassium, it is a double cyanide of iron and potassium; but the equivalent proportion of the two cyanides is reversed. As it appears in practice, it is apt to be greenish, owing probably to the presence of a little Prussian blue.

According to the late Mr. Phillips, an excess of sulphuric acid would endanger the production of formic acid. The proportion of the acid should not exceed three-fourths of the weight of the ferrocyanide. In relation to the most convenient method of bringing the hydrocyanic acid to the standard strength, and to some other points in its preparation by the officinal formula, the reader is referred to a paper by Prof. Procter in the *Am. Journ. of Pharm.* (xix. 259).

In the U. S. process for obtaining hydrocyanic acid extemporaneously, the reacting materials are single equivalents respectively of cyanide of silver and muriatic acid. These, by double decomposition, generate hydrocyanic acid which dissolves in the water, and chloride of silver which subsides, and from which the acid is poured off when clear. (See *Argenti Cyanidum.*) The extemporaneous process is useful to country practitioners; because the acid will not generally keep. A portion of hydrocyanic acid, if purchased by a practitioner, may spoil on his hands, before he has occasion to use it; but if he supply himself with cyanide of silver, he may readily at any moment prepare a small portion of the acid, by following the directions of the formula.

The French Codex of 1837 gives the following process for hydrocyanic acid, in place of the three previously contained in that work. Take of bicyanide of mercury thirty parts; muriatic acid (sp. gr. 1·17) twenty parts. Reduce the bicyanide to powder, and introduce it into a small tubulated glass retort, placed over a furnace. Adapt to its neck a tube about 13 inches long, and half an inch

in diameter, and filled one-half with pieces of marble, and the remainder with chloride of calcium. To this tube, arranged nearly horizontally, adapt a smaller one, bent at a right angle, and plunging into a graduated tube, surrounded with a mixture of common salt and pounded ice. The apparatus being thus arranged, and the junctures well luted, add the muriatic acid; and, having allowed the action to take place for a few moments in the cold, apply the heat gradually. When the action is over, drive forward any acid which may have condensed in the large tube, by means of a live coal brought near to it, and passed along its whole length. The quantity of acid found in the graduated tube is mixed with either six times its bulk, or eight and a half times its weight, of distilled water. In this process Gay-Lussac's strong acid is first obtained in the graduated tube, and afterwards diluted to a given extent with water. The object of the marble and chloride of calcium is to detain, the former muriatic acid, the latter water.

Another process for obtaining medicinal hydrocyanic acid, proposed by Dr. Clark, and adopted by Mr. Laming, is by the reaction of tartaric acid on cyanide of potassium in solution. Laming's formula is as follows. Dissolve twenty-two grains of the cyanide in six fluidrachms of distilled water, and add fifty grains of crystallized tartaric acid, dissolved in three fluidrachms of rectified spirit. Crystallized bitartrate of potassa precipitates, and each fluidrachm of the clear decanted liquor contains one grain of pure hydrocyanic acid. The reaction in this process takes place between two eqs. of tartaric acid, one of cyanide of potassium, and one of water. The water is decomposed, and the tartaric acid, potassium, and oxygen unite to form the bitartrate, and the cyanogen and hydrogen to form the hydrocyanic acid. Dr. Pereira considered this process to have several advantages, but very properly objected to it on account of the trouble and expense of obtaining the cyanide of potassium pure, and its liability to undergo spontaneous decomposition. (See *Potassii Cyanidum.*)

The processes, thus far given, are intended to furnish a *dilute* hydrocyanic acid for medicinal purposes. The methods of obtaining the *anhydrous* acid are different. Vauquelin's process for the anhydrous acid is to pass a current of hydrosulphuric acid gas over the bicyanide of mercury contained in a glass tube, connected with a receiver kept cold by a freezing mixture of ice and salt. The first third only of the tube is filled with the bicyanide; the remaining two-thirds being occupied, half with carbonate of lead, and half with chloride of calcium; the carbonate being intended to detain the hydrosulphuric acid gas, the chloride to separate water. Another process for the anhydrous acid is that of Gautier, thus described by Berzelius. Ferrocyanide of potassium is fused without access of air, whereby it is converted into a mixture of cyanide of potassium and carburet of iron. The mass obtained, after having been pulverized and placed in a flask, is slightly moistened with water, and acted on with muriatic acid, added by small portions at a time. By a double decomposition between the cyanide and muriatic acid, chloride of potassium and hydrocyanic acid are formed. The flask is then plunged into hot water, which causes the hydrocyanic acid to be disengaged in form of vapour. This is passed through a tube containing chloride of calcium, and finally received in a small flask kept cool by a freezing mixture.

The process of Wöhler for the anhydrous acid is the following. The cyanide of potassium selected is a black cyanide, formed by fusing together, in a covered crucible, 8 parts of dry ferrocyanide, 3 of ignited cream of tartar, and 1 of charcoal in fine powder. The cyanide, while still warm, is exhausted by 6 parts of water; and the clear solution, placed in a retort, is decomposed by cold diluted sulphuric acid, gradually added. The hydrocyanic acid is condensed first in a U-tube, containing chloride of calcium, and surrounded with ice-cold water, and afterwards in a small bottle, connected with the U-tube by a narrow tube, and immersed up to the neck in a mixture of ice and salt. After the acid has been condensed and dehydrated in the U-tube, the cold water surrounding it is with drawn by a syphon, and replaced by water at a temperature between 85° and 90°, whereby the anhydrous acid is made to distil over into the small bottle.

Properties of the Medicinal Acid. Diluted hydrocyanic acid, of the proper

medicinal strength, is a transparent, colourless, volatile liquid, possessing a peculiar smell, and a taste at first cooling and afterwards somewhat irritating. It imparts a slight and evanescent red colour to litmus. If it reddens litmus strongly and permanently, the fact shows the presence of some acid impurity. It is not reddened by the iodo-cyanide of potassium and mercury. The non-action of this test shows the absence of contaminating acids, which, if present, would decompose the test, and give rise to the red iodide of mercury. It is liable to undergo decomposition if exposed to the light, but is easily kept in a bottle covered with black paint or black paper. From experiments carefully conducted by MM. Bussy and Buignet, it appears that, when the alteration in the acid under the influence of light has begun, it will afterward go on very rapidly in the dark; and that, after exposure for a certain time to the light, though no alteration may be apparent, an influence has nevertheless been exerted which disposes to change, and promotes decomposition even in the absence of light. Hence the necessity of immediately enclosing the acid in bottles from which the light is excluded. (*Journ. de Pharm.*, Dec. 1863, p. 475.)* Its most usual impurities are sulphuric and muriatic acids; the former of which may be detected by chloride of barium, which will produce a precipitate of sulphate of baryta; and the latter, by precipitating with nitrate of silver, when so much of the precipitate as may be chloride of silver will be insoluble in boiling nitric acid, while the cyanide of silver is readily soluble. The presence of these acids, in slight amount, is injurious only by rendering uncertain the strength of the medicinal acid, as ascertained by its saturating power. Indeed, Mr. Barry, of London, was in the habit of adding a small proportion of muriatic acid to all his medicinal hydrocyanic acid, in order to preserve it. But the presence of a mineral acid is not necessary for its preservation; for Dr. Christison has known the medicinal acid from ferrocyanide of potassium to keep perfectly well, although nitrate of baryta did not produce the slightest muddiness. If lead be present, it may be detected by hydrosulphuric acid gas, which will cause a blackish precipitate. Hydrocyanic acid is incompatible with nitrate of silver, the salts of iron and copper, and most of the salts of mercury.

Formerly the medicinal acid was of different strengths, as ordered by the different pharmaceutical authorities; but happily the U. S. and Br. Pharmacopœias conform in this important point. At one time its strength was indicated by its specific gravity, which is lower in proportion as it is stronger; but this unprecise mode of estimate is not now relied on; and, though the Br. Pharmacopœia gives the sp. gr. of its dilute acid at 0·997, yet both it and that of the United States give the saturating power as an index of the strength. According to the *United States* formula, 100 grains of the acid must accurately saturate 12·7 grains of nitrate of silver dissolved in distilled water, and produce a white precipitate (cyanide of silver), which, when washed and dried, at a temperature not exceeding 212°, shall weigh 10 grains, and be wholly soluble in boiling nitric acid. The Br. Pharmacopœia directs that 270 grains of it,

* Anhydrous hydrocyanic acid sometimes undergoes an apparently spontaneous molecular change, by which it is converted into a black solid body, supposed to be *paracyanogen* ($2NC_2$ or N_2C_4), or its compounds. This change takes place more slowly in watery solutions of the acid, which are converted into a black liquid; and it is only in a state of extreme dilution, when, for example, water contains not more than one per cent. of the acid, that it is altogether prevented. It sometimes takes place in the officinal diluted acid; and Prof. Procter has shown us a bottle, which had been most carefully closed, and kept excluded from the light, and in which, nevertheless, the acid had become as black as ink. The cause of this phenomenon remained long unknown; but recently M. E. Millon has satisfied himself, by experiment, that the real agency is the presence of ammonia, which may sometimes operate even through the air. (*Journ. de Pharm.*, Janv. 1862, p. 48.) The preservative influence of a little sulphuric acid in the diluted hydrocyanic acid is thus explained; and it is not impossible that the greater resistance offered to the change by the preparation made by the officinal process, in which sulphuric acid is used, than by the others, may be owing to the influence of this acid, either passing over with its vapour, or acting on the acid vapour before it leaves the retort. An important practical inference from all this is the necessity of providing, as far as possible, that ammonia should in no manner have access to the acid, during or after its preparation. (*Note to the twelfth edition.*)

when treated with solution of soda in excess, shall require the addition of 1000 grain-measures of the *volumetric solution of nitrate of silver*, before a permanent precipitate begins to form. To explain this test it is necessary to notice that cyanide of silver, though itself insoluble, is rendered soluble by combining with cyanide of sodium, in the proportion of one eq. of each. When, therefore, the diluted hydrocyanic acid is converted, by the addition of soda, into cyanide of sodium, no permanent precipitate will begin to appear, upon the addition of nitrate of silver, until more than sufficient cyanide of silver is produced to form the soluble compound referred to, which happens when one-half of the cyanide of sodium has been converted into cyanide of silver. An acid of the strength indicated by either of these methods, contains two per cent. of anhydrous acid. The test of entire solubility in boiling nitric acid, applied to the precipitate obtained by nitrate of silver, is intended to verify its nature; for, if the hydrocyanic acid contain muriatic acid, part of this precipitate would be chloride of silver, not soluble in the boiling acid. Scheele's medicinal hydrocyanic acid contains about 5 per cent. of anhydrous acid; and, therefore, two minims of it are equal to five of the U. S. acid. The use of Scheele's acid should be discouraged as unnecessary, and as leading to dangerous mistakes.

MM. Fordos and Gélis have proposed, as a test of the strength of the compounds containing cyanogen, an alcoholic solution of iodine of known strength; as, for example, three grains to the fluidounce. The test solution is added, drop by drop, to the cyanogen compound, until a permanent yellowish tinge is produced. The iodine unites with the cyanogen, and with the substance in combination with the cyanogen, in the ratio of their several equivalents; and hence the cyanogen present is easily calculated from the proportion of iodine expended in uniting with it. This test is commended for its accuracy by Mr. James Roberton, of Manchester. (See *Am. Journ. of Pharm.*, Nov. 1853, p. 551.)

Properties of the Anhydrous Acid. Hydrocyanic acid, perfectly free from water, is a colourless, transparent, inflammable liquid, of extreme volatility, boiling at 80°, and congealing at 5°. Its sp. gr. as a liquid is 0·6969, at the temperature of 64°; and as a vapour 0·9423. Its taste is at first cooling, then burning, with an after-taste in the throat like that of bitter almonds; but, from its extremely poisonous nature, it must be tasted with the utmost caution. Its odour is so strong as to produce immediate headache and giddiness; and its vapour so deleterious that the smallest portion of it cannot be inhaled without the greatest danger. Both water and alcohol dissolve it readily. It is much more prone to undergo decomposition than the dilute acid. In the course of a few hours, it sometimes begins to assume a reddish-brown colour, which becomes gradually deeper, till at length the acid is converted into a black liquid, which exhales a strong smell of ammonia. It is a very weak acid in its chemical relations, and reddens litmus but slightly. It does not form solid compounds with metallic oxides, but a cyanide of the metal, the elements of water being exhaled. According to Sobero, hydrocyanic acid is generated, in sensible quantities, by the action of weak nitric acid on the volatile oils and resins. It has also been formed by the slow action of carbonate of potassa on tincture of hyoscyamus, given together as a medicine. (Dr. J. T. Plummer, of Indiana, *Am. Journ. of Pharm.*, xxv. 513.) Though a product of art, it exists in some plants, and is generated by reaction between the constituents of many vegetable products upon contact with water. (See *Amygdala Amara.*)

Composition, &c. Hydrocyanic acid consists of one eq. of cyanogen 26, and one of hydrogen 1 = 27; or, in volumes, of one volume of cyanogen and one of hydrogen without condensation, its formula being HNC_2 or HCy. *Cyanogen* (Cy) is a colourless gas, of a strong and penetrating smell, inflammable, and burning with a beautiful bluish-purple flame. Its sp. gr. is 1·8157. It was discovered in 1815 by Gay-Lussac, who viewed it as a compound radical, which, when acidified by hydrogen, becomes hydrocyanic acid. It consists of two eqs. of carbon 12, and one of nitrogen 14 = 26; or, in volumes, of two volumes of carbon vapour and one of nitrogen, condensed into one volume. The ultimate constituents of the acid are, therefore, two eqs. of carbon, one of nitrogen, and one of hydrogen.

Hydrocyanic acid, in a dilute state, was discovered in 1780 by Scheele, who correctly stated its elements to be carbon, nitrogen, and hydrogen; but the peculiar way in which they are combined was first pointed out by Gay-Lussac, by whom also the anhydrous acid was first obtained.

Medical and Toxical Properties. Hydrocyanic acid is one of the most deadly poisons known proving, in many cases, almost instantaneously fatal. According to Dr. Christison, a grain and a half of the anhydrous acid is capable of producing death in the human subject. One or two drops of the pure acid are sufficient to kill a vigorous dog in a few seconds. The post-mortem appearances are glistening and staring expression of the eyes; gorged state of the venous system with fluid, dark, or bluish-black blood, especially of the veins of the brain and spinal marrow; and sometimes redness of the internal coat of the stomach. The lungs are sometimes natural, at other times turgid with blood. It is not true, or rarely true, that the muscles are insensible to the galvanic current. Notwithstanding the tremendous energy of this acid as a poison, it has been ventured upon in a dilute state as a sedative, anodyne, and antispasmodic. Though occasionally employed as a remedy prior to 1817, yet it did not attract much attention until that year, when Magendie published his observations on its use in diseases of the chest, and recommended it to the profession. When given in medicinal doses gradually increased, it produces the following symptoms in different cases; peculiar bitter taste; increased secretion of saliva; irritation of the throat; nausea; disordered respiration; pain in the head; giddiness; faintness; obscure vision; and tendency to sleep. It appears to have a special action on the larynx and trachea. (*Dr. Cogswell.*) The pulse is sometimes quickened, at other times reduced in frequency. Occasionally salivation and ulceration of the mouth are produced. It has been extensively used in complaints of the respiratory organs, and is supposed to exert a control over pulmonary inflammation, after the excitement has been diminished by blood-letting; and there is no doubt that, in some instances, it has proved beneficial under such circumstances. Dr. Joseph Johnson, of Charleston, S. C., found it useful in pneumonia. In phthisis it may be resorted to with advantage as a palliative for the cough. In various other affections of the chest, attended with dyspnœa or cough, such as asthma, hooping-cough, and chronic catarrh, it has often been decidedly beneficial, by allaying irritation or relaxing spasm. In hypertrophy of the heart and aneurism of the aorta, it has also been used with benefit. In certain affections of the stomach, characterized by pain and spasm, and sometimes attended with vomiting, but unconnected with inflammation, and in similar painful affections of the bowels, it has proved beneficial in the hands of several practitioners. It has also been administered as an anodyne in several painful affections, as cancer, tic douloureux, &c., but with doubtful advantage. In mania, it is often useful in the paroxysmal excitement characteristic of that disease, and occasionally has been thought to contribute to a cure by its permanent action. (*Ann. de Thérap.*, 1865, p. 111.) Sometimes it is used externally, diluted with water, as a wash in cutaneous diseases. The late Dr. A. T. Thomson insisted particularly on its efficacy in allaying the itching of impetiginous affections.

The dose of the diluted hydrocyanic acid is from two to six drops, dissolved in distilled water, or mixed with gum-water or syrup. It should be administered with the greatest caution, on account of its minute dose, and variable strength as found in the shops. The proper plan, therefore, is to begin with a small dose, two drops for example, and gradually to increase the quantity until some obvious impression is produced. If giddiness, weight at the top of the head, sense of tightness at the stomach, or faintness come on, its use should be discontinued. In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum quantity, lest the new sample should prove stronger than that previously employed. When resorted to as a lotion, from thirty minims to a fluidrachm may be dissolved in a fluidounce of distilled water.

Toxicology. Hydrocyanic acid is so rapidly fatal as a poison that physicians have seldom an opportunity to treat its effects. When not immediately fatal,

the symptoms produced are sudden loss of sense, trismus, difficult and rattling respiration, coldness of the extremities, smell of the acid proceeding from the mouth, though this is sometimes absent, smallness of the pulse, swelling of the neck, dilatation, immobility, and sometimes contraction of the pupils, convulsions, &c. The antidotes and remedies, most to be relied on, are chlorine, ammonia, cold affusion, and artificial respiration. Chlorine in the form of chlorine water, or weak solutions of chlorinated lime or soda, may be exhibited internally, or applied externally. When chlorine is not at hand, water of ammonia, largely diluted, may be given, and the vapour arising from it cautiously inhaled. A case is related, in the *Dublin Med. Journal* for Nov. 1835, of poisoning by this acid, in which the diluted aromatic spirit of ammonia applied to the mouth, and the solid carbonate assiduously held to the nostrils, produced speedy and beneficial effects. Cold affusion was first proposed in 1828 by Herbst, of Göttingen, and its utility was subsequently confirmed by Orfila. Its efficacy is strongly supported by experiments performed in 1839 by Dr. Robinson and M. Lonyet, who quickly resuscitated rabbits, apparently dead from hydrocyanic acid, by pouring on their head and spine a stream of water, artificially refrigerated. In a case of poisoning, reported by Dr. Christison in 1850, the patient recovered under a stream of cold water, poured upon the head from a moderate height. In another case, reported in the *Lancet* in 1854, in which the largest recorded quantity was taken to be followed by recovery (2·4 grains of anhydrous acid), the cold water douche was the principal remedy. (See *Am. Journ. of Med. Sci.*, July, 1854, p. 276.) Messrs. T. & H. Smith, of Edinburgh, have recommended, as an antidote for the medicinal acid, a mixture of the sulphates of the protoxide and sesquioxide of iron, swallowed after a solution of carbonate of potassa. So soon as the antidote comes in contact with hydrocyanic acid, sulphate of potassa is formed, and the poison is converted into Prussian blue. It may be prepared extemporaneously, by adding ten grains of sulphate of protoxide of iron, and a drachm of the tincture of chloride of iron, to a fluidounce of water contained in one vial, and twenty grains of carbonate of potassa to a fluidounce of water in another vial. The patient is made to swallow the solution of carbonate of potassa, and immediately afterwards the mixed ferruginous solution. This quantity is estimated to be sufficient to render insoluble nearly two grains of the anhydrous acid.* In one instance this antidote is said to have proved effectual. (*Pharm. Journ. and Trans.*, Oct. 1865, p. 139.) *Atropia* has been proposed as a counter-poison, on the grounds of its physiological action, and of experiments made with it on the lower animals. M. W. Preyer has injected sulphate of atropia beneath the skin in rabbits and guinea-pigs to which hydrocyanic acid had been applied in the same way, and ascertained from the result that, if administered pretty quickly after the injection of the poison, it will prove an unfailing antidote. (See *Am. Journ. of Med. Sci.*, Oct. 1868, p. 577.)

Tests. After death from suspected poison, it is sometimes necessary to ascertain whether the event was caused by this acid. At a period long after death, it would be needless to search for so volatile a poison; but it has been recognised three weeks after death, in a case reported by M. Brame, in which about six drachms of acid, containing between 8 and 9 per cent of anhydrous acid, had

* In a subsequent communication the Messrs. Smith recommend the following proportions. Mix of solution of perchloride of iron (*Br.*) 37 minims, crystallized protosulphate of iron, as pure as possible, 25 grains, and about half a fluidounce of water. Dissolve 77 grains of crystallized carbonate of soda in the same measure of water. These quantities will neutralize between 150 and 200 minims of medicinal hydrocyanic acid. (*Pharm. Journ. and Trans.*, Oct. 1865, p. 147.) Still more recently the authors propose to substitute magnesia for carbonate of soda, as better fitted to neutralize any considerable quantity of gastric acid that might be present. The following is the formula now recommended. From one to two drachms of magnesia, made into a smooth cream with water, is to be first administered, and then 16 minims of solution of perchloride of iron (*Br.*) and 12½ grains of green vitriol dissolved together in water. These quantities are calculated for 100 minims of medicinal hydrocyanic acid. Should more than this be supposed to have been taken, the ferruginous ingredients must be increased in proportion, but not the magnesia. (*Ibid* Nov. 1865, p. 276.)—*Note to the thirteenth edition.*

been swallowed. The best test is that proposed by Liebig in 1847, consisting in the change of the hydrocyanic acid into hydrosulphocyanate of ammonia, which salt is then tested with a sesquioxide salt of iron. Two drops of the acid, so dilute as not to afford the least blue tint with the salts of iron, upon being mixed with a drop of bihydrosulphate of ammonia, and heated upon a watch-glass until the mixture is colourless, yields a solution of hydrosulphocyanate of ammonia, which becomes of a deep blood-red colour upon the addition of the sulphate of sesquioxide of iron, in consequence of the formation of the sulphocyanide of iron. (*Chem Gaz*, April 1, 1847; from Liebig's *Annalen.*) This test is praised by Mr. A. S. Taylor, who found it to act characteristically on two grains of dilute hydrocyanic acid, containing only 1-3930th of a grain of anhydrous acid To render the test thus delicate, Mr. Taylor deems it necessary to evaporate the liquid gently to dryness, after the addition of the bihydrosulphate of ammonia, in order to bring the hydrosulphocyanate to the solid state before adding the iron test, a fractional part of a drop of which will commonly suffice to produce the characteristic colour. Should the acid be mixed with organic matters, Mr. Taylor proposes a modification of Liebig's test as follows. Place it in a watch-glass, and invert over it another, holding in the centre a drop of bihydrosulphate of ammonia. In from half a minute to ten minutes, without heat, the bihydrosulphate will be converted into the hydrosulphocyanate of ammonia; and, upon removing the upper glass, and evaporating its contents to dryness, the iron test will produce the blood-red colour. MM. O. Henry and E. Humbert have proposed, as a test of hydrocyanic acid, first to convert it into cyanide of silver by distilling the suspected matters into a dilute solution of nitrate of silver, and then to decompose the cyanide by iodine, so as to form iodide of cyanogen. The dried cyanide is added to half its estimated weight of *pure* iodine, contained in a test tube. Upon the application of a gentle heat, iodide of cyanogen is formed, and characteristic crystals of it are deposited on the cool surface of the tube. (*Journ. de Pharm*, Mars, 1857, p. 173.)

An extremely sensitive test of hydrocyanic acid, in the state of vapour, has recently been offered by Schönbein. It consists of white filtering paper imbued with the resin of guaiacum, by dipping it in a solution of 3 parts of the resin in 150 of alcohol, and then dried, and at the moment of use moistened with a solution of sulphate of copper containing 1 part in 500 of water. If now brought into contact with hydrocyanic acid, whether dissolved in water or diffused in the air in the form of vapour, it instantly becomes blue. According to Schönbein, it will change colour in air containing only a forty millionth of hydrocyanic acid. (See *Am. Journ. of Pharm.*, March, 1869, p. 174.)

ACIDUM MURIATICUM DILUTUM. *U. S.* Acidum Hydrochloricum Dilutum. *Br.* *Diluted Muriatic Acid.* *Dilute Hydrochloric Acid.*

"Take of Muriatic Acid *four troyounces;* Distilled Water *a sufficient quantity.* Mix the Acid, in a glass vessel, with sufficient Distilled Water to make the Diluted Acid measure a pint. The sp. gr. is 1·038." *U. S.*

"Take of Hydrochloric Acid *eight fluidounces* [Imperial measure]; Distilled Water a sufficiency. Dilute the Acid with 16 ounces [avoird.] of the water; then add more water, so that, at a temperature of 60°, it shall measure 26½ fluidounces [Imp. meas.]. Or, as follows: Take of Hydrochloric Acid 3060 grains; Distilled Water *a sufficiency.* Weigh the Acid in a glass flask, the capacity of which, to a mark on the neck, is one pint [Imp. meas.]; then add Distilled Water until the mixture, at 60° temperature, after it has been shaken, measures a pint [Imp. meas.]." *Br.*

The existing U. S. formula differs from that of 1850 in substituting four troyounces for four fluidounces. In both, the resulting diluted acid measures a pint The present is somewhat weaker than the former diluted acid, having the sp. gr. 1·038, while that of 1850 was 1·046; but the difference is of no practical importance as regards the dose, the diminution in strength amounting only to about

one-eleventh of the whole. We doubt, however, the expediency of changing measures for weights in preparing the diluted acids; for, though the latter method may be practically somewhat more accurate, the former is more convenient, especially for the large body of physicians practising in the country, who are not generally so well provided as the regular pharmaceutists with all requisite implements. The British preparation is stronger even than ours of 1850, having the sp. gr. 1·052. "345 grains by weight (6 fluidrachms) require for neutralisation 1000 grain-measures of the *volumetric solution of soda*, corresponding to 10·58 per cent. of real acid. Six fluidrachms [Imperial] contain one eq. or 36·5 grains of hydrochloric acid HCl." *Br.* The extreme precision of the British formula, though no doubt useful when the diluted acid is used as a test, is quite unnecessary in a therapeutical point of view.

The medical properties and applications of muriatic acid have been detailed in *Part* I., under the head of *Acidum Muriaticum*. The dose of the diluted acid is from twenty minims or drops to a fluidrachm, and may be taken in water or other convenient vehicle, sweetened or not as may be deemed expedient.

ACIDUM NITRICUM DILUTUM. *U. S., Br. Diluted Nitric Acid.*

"Take of Nitric Acid [sp. gr. 1·42] *three troyounces;* Distilled Water *a sufficient quantity*. Mix the Acid, in a glass vessel, with sufficient Distilled Water to make the Diluted Acid measure a pint. The sp. gr. of Diluted Nitric Acid is 1·068." *U. S.*

"Take of Nitric Acid *six fluidounces* [Imperial measure], Distilled Water *a sufficiency*. Dilute the Acid with 24 fluidounces [Imp. meas.] of the Water; then add more water, so that at a temperature of 60° it shall measure 31 fluidounces [Imp. meas.]. Or as follows:

"Take of Nitric Acid 2400 grains, Distilled Water *a sufficiency*. Weigh the Acid in a glass flask, the capacity of which, to a mark on the neck, is one pint [Imp. meas.]; then add Distilled Water until the mixture, at 60° temperature, after it has been shaken, measures a pint." *Br.*

The U. S. acid, as now directed, varies little from the former officinal acid, which was made by mixing a fluidounce of the officinal nitric acid with six fluidounces of distilled water, and had the sp. gr. 1·07; while the present preparation contains three troyounces in a pint of the diluted acid, and has the sp. gr. 1·068; being only about one-thirty-eighth weaker, which is a difference of no practical importance. This cannot be said of the new British diluted acid, which is considerably stronger than our own in the same measure, or even than the strongest diluted acid of the former Pharmacopœias. The British preparation has the sp. gr. 1·101; and "361 grains by weight (six fluidrachms) require for neutralisation 1000 grain-measures of the *volumetric solution of soda*, corresponding to 14·95 per cent. of anhydrous nitric acid. Six fluidrachms [Imp. meas.], therefore, correspond to 54 grains of the anhydrous acid (one eq. of NO_5)." *Br.*

In making the U. S. diluted acid, the apothecary should be careful to use acid of the sp. gr. 1·42; or, if the acid used is weaker than this, to add proportionally less water; otherwise the diluted acid would be weaker than it is directed to be in the Pharmacopœia.

The medicinal properties of the diluted acid are the same as those of the strong acid. (See *Acidum Nitricum.*) The dose of the U. S. diluted acid is from twenty to forty drops or minims, that of the British, from fifteen to thirty, three times a day, sufficiently reduced with water at the time of taking it. B.

ACIDUM NITROMURIATICUM. *U. S. Nitromuriatic Acid.*

"Take of Nitric Acid [sp. gr. 1·42] *three troyounces;* Muriatic Acid *five troyounces*. Mix the Acids in a glass vessel, and, when effervescence has ceased, keep the product in a well-stopped bottle, in a cool place, protected from the light." *U. S.*

In the old formula four fluidounces of nitric acid were mixed with eight fluidounces of muriatic acid, or in the proportion of one to two by measure. The difference between the old and new acid is insignificant, the muriatic acid being, according to the calculation of Mr. A. B. Taylor, one-forty-ninth increased. (*Am. Journ. of Pharm.*, Sept. 1863, p. 410.)

Nitromuriatic acid is the *aqua regia* of the earlier chemists, so called from its property of dissolving gold. Nitric and muriatic acids, when mixed together, mutually decompose each other. According to the researches of Gay-Lussac (June, 1848), the reaction gives rise to two compounds, in variable proportions, of nitric oxide and chlorine (NO_2Cl_2 and NO_2Cl), mixed with free chlorine; the former being analogous in constitution to hyponitric, the latter to nitrous acid. The power, however, of nitromuriatic acid to dissolve gold, and similar metals having a weak affinity for oxygen, is owing exclusively to the free chlorine present, and is in no wise dependent on the compounds above referred to, which remain entirely passive during the solution of the metal. (*Journ de Pharm.*, Août, 1848.) Adopting the views of Gay-Lussac, the proportion of the acids for total mutual decomposition would be two eqs. of nitric and six of muriatic acid; and the products would be the two compounds of nitric oxide and chlorine, free chlorine, and water. Assuming this proportion, it follows that a large excess of nitric acid is employed in the U. S. formula. According to the same views, the proportion of free chlorine must be variable, dependent upon the relative proportion of the nitric oxide compounds to each other. For every eq. of NO_2Cl_2 formed, one eq. of chlorine will be set free; while for every eq. of NO_2Cl, two eqs. of chlorine will be evolved. The precise circumstances that determine the simultaneous formation of the two nitric oxide compounds, and their constantly varying proportion to each other, have not been pointed out by Gay-Lussac in the paper above referred to. When nitromuriatic acid is made from strong acids, there is always a loss of the nitric oxide compounds and of free chlorine by effervescence, in consequence of the acids not containing sufficient water to hold the gaseous products in solution. Hence the substitution, in the U. S. Pharmacopœia of 1850, of nitric acid of 1·42 for the acid of 1·5 was an improvement.

Properties. Nitromuriatic acid has a golden-yellow colour, and the odour of chlorine. It possesses the power of dissolving gold and platinum. It should be kept in a cool dark place, on account of its liability to lose chlorine by heat, and to have it converted, by the action of light, into muriatic acid, through the decomposition of water. On account of its tendency to decomposition, it should not be made in large quantities, nor be very long kept by the apothecary; and care should be taken not to transfer it to the bottle in which it is to be dispensed, until effervescence has ceased, lest the pressure within should drive out the stopper. Nitric and muriatic acids, as found in the shops, are sometimes so weak that when mixed they will not readily act on gold-leaf. In this case, their solvent power may be rendered effective by the addition of a little sulphuric acid, which, by its superior affinity for water, concentrates the other acids, and causes immediate action.*

Medical Properties and Uses. Nitromuriatic acid was brought to the notice of the profession, in consequence of the favourable report of its efficacy as an external remedy in hepatitis, made by Dr. Scott, formerly of Bombay. When thus employed, it produces a tingling sensation of the skin, thirst, a peculiar taste in the mouth, and occasional soreness of the gums and plentiful ptyalism; and at the same time stimulates the liver, as is evinced by an increased flow of bile. It is used either by sponging, or in the form of a local or general bath. When applied by sponging, the acid is first diluted so as to have the sourness of strong vinegar. When used as a foot-bath, three gallons of water, contained in a deep narrow wooden tub, may be acidulated with six fluidounces of the acid. In this the feet and legs are to be immersed for twenty minutes or half an hour. The bath may be employed at first daily, and afterwards twice or thrice a week; and the

* In relation to nitromuriatic acid, see a paper in the third volume of the Journal of the Philadelphia College of Pharmacy, by Mr. Daniel B. Smith, of this city.

sponging may be used at the same time. The bath is said to be effective in promoting the passage of biliary calculi. The solution, prepared for a bath as above mentioned, may be used for a week, adding to it daily a pint of water, acidulated with two fluidrachms of the acid, to make up for the waste by evaporation. The bath should have a temperature of about 97°, which may be attained by heating part of the acid solution, and throwing it back into the remainder. For some good directions for the preparation and use of the nitromuriatic acid bath, by Mr. Ranald Martin, the reader is referred to the *Pharmaceutical Journal* for July, 1851, p. 38.

Nitromuriatic acid is much used internally, and is an excellent remedy in chronic hepatic affections, and in oxaluria. It is sometimes given also in syphilitic diseases. The dose is three or four drops, largely diluted with water. B.

ACIDUM NITROMURIATICUM DILUTUM. *U.S.* ACIDUM NITRO-HYDROCHLORICUM DILUTUM. *Br.* *Diluted Nitromuriatic Acid. Dilute Nitro-hydrochloric Acid.*

"Take of Nitric Acid *a troyounce and a half;* Muriatic Acid *two troyounces and a half;* Distilled Water *a sufficient quantity.* Mix the Acids in a well-stopped bottle, having the capacity of a pint. Shake them together occasionally during twenty-four hours, and then add sufficient Distilled Water to make the Diluted Acid measure a pint. Lastly, keep it in a cool place, protected from the light." *U.S.*

"Take of Nitric Acid *three fluidounces;* Hydrochloric Acid *four fluidounces* [Imperial measure]; Distilled Water *twenty-five fluidounces* [Imp. meas.]. Mix the Acids, and allow them to remain for twenty-four hours in a bottle, the mouth of which is partially closed, then add the Water in successive portions, shaking the bottle after each addition, and preserve the mixture in a stoppered bottle. Sp. gr. 1·074. Six fluidrachms [Imp. meas.] (352·4 grains by weight) require for neutralisation 920 grain-measures of the *volumetric solution of soda.*" *Br.*

This is a new officinal in both Pharmacopœias, having been adopted in the British as a substitute for the stronger acid of the former Dublin Pharmacopœia. The strength of the U. S. and Br. diluted acids is about the same.

In the first Br. Pharmacopœia the two strong acids were diluted with water before being allowed to react on each other. To this process, as stated in the preceding edition of the Dispensatory, that of the U. S. Pharmacopœia was decidedly preferable. In this, the acids, being mixed in their concentrated state, react on each other, producing changes with which the peculiar therapeutic virtues of nitromuriatic acid are essentially connected. In the British process (1864), the acids were so much diluted as to interfere with their mutual reaction, and the result was little more than a mere mixture of nitric and muriatic acids, with their joint virtues, but destitute of the peculiar properties which give to the nitromuriatic acid any special importance. The strong acids should first be mixed, and allowed some time for mutual reaction, before being diluted. After reaction has sufficiently taken place, there is an advantage in diluting the acid, as the evolved products are better retained by the larger amount of menstruum, and the diluted acid is in a much better condition for being dispensed. It will have been perceived that, in the present Br. Pharmacopœia, the original formula has been abandoned, and that of the U. S. Pharmacopœia essentially adopted.

This preparation may be given for all the purposes which the nitromuriatic acid is calculated to answer. The dose is from ten to twenty drops or minims, three times a day, and may be given in a large wineglassful of water, sweetened or not as may be deemed expedient. W.

ACIDUM PHOSPHORICUM DILUTUM. *U.S.*, *Br.* *Diluted Phosphoric Acid.*

"Take of Phosphorus *three hundred and sixty grains;* Nitric Acid *five troyounces,* or *a sufficient quantity;* Distilled Water *a sufficient quantity.* Mix

five troyounces of Nitric Acid with half a pint of Distilled Water, in a porcelain capsule, of the capacity of two pints. Add the Phosphorus, and invert over it a glass funnel of such dimensions that its rim may rest on the inside of the capsule, near the surface of the liquid. Place the capsule on a sand-bath, and apply a moderate heat until the Phosphorus is dissolved, and red vapours cease to rise. If the reaction become too violent, add a little Distilled Water; and if the red vapours cease to be evolved before the Phosphorus is all dissolved, gradually add Nitric Acid, diluted to the same extent as before with Distilled Water, until the solution is effected. Then, removing the funnel, continue the heat until the excess of nitric acid is driven off, and a syrupy liquid, free from odour and weighing two [troy]ounces, remains. Lastly, mix this, when cold, with sufficient Distilled Water to make it measure twenty fluidounces, and filter through paper.

"Diluted Phosphoric Acid may also be prepared by dissolving a troyounce of Glacial Phosphoric Acid in three fluidounces of Distilled Water, adding to the solution forty grains of Nitric Acid, boiling it until reduced to a syrupy liquid, free from the odour of nitric acid, and then adding sufficient Distilled Water to make the Diluted Acid measure twelve fluidounces and a half." *U. S.*

"Take of Phosphorus *four hundred and thirteen grains;* Nitric Acid *six fluidounces* [Imperial measure]; Distilled Water *a sufficiency.* Put the Nitric Acid, diluted with eight [fluid]ounces [Imp. meas.] of Distilled Water, into a tubulated retort connected with a Liebig's condenser, and, having added the Phosphorus, apply a gentle heat, so as slowly to distil five fluidounces [Imp. meas.] of liquid. Return this to the retort, and continue the distillation, occasionally returning the distillate, until the phosphorus has entirely disappeared. Transfer the contents of the retort to a porcelain dish of hard well-enamelled ware, and evaporate the liquid until it is reduced to four fluidounces [Imp. meas.]; then, transferring it to a platinum vessel, continue the evaporation until it is reduced to about two fluidounces [Imp. meas.], and orange-coloured vapours are no longer formed. Mix it now with Distilled Water until, when cold, it measures one pint [Imp. meas.]." *Br.*

This is a new officinal of the U. S. Pharmacopœia; and the first formula differs only in its manipulations from the British, which is essentially that of the late London Pharmacopœia. In both, phosphorus is oxidized at the expense of the nitric acid, which, in giving up a portion of its oxygen to the phosphorus, is converted into nitric oxide, becoming red hyponitric acid vapours as it escapes. Strong nitric acid acts too energetically on phosphorus, producing explosion and rapid combustion; but when diluted, as in the processes above given, it parts with its oxygen slowly, and it is even desirable to aid the operation with a gentle heat. Along with the nitrous fumes, a portion of the undecomposed nitric acid also rises in vapour, which, in the British process, to prevent loss, is collected by means of a distillatory apparatus, and returned into the retort. In the U. S. process, the same end is effected by placing over the liquid in the capsule a glass funnel, upon the inner surface of which the acid is condensed, and returns of itself into the capsule, so as considerably to simplify the operation. This modification was originally suggested by Mr. Geo. W. Andrews, of Baltimore, who, however, inverted a dish over the materials; the suggestion of the funnel being due to Prof. Procter. The operation being continued till the whole of the phosphorus is converted into phosphoric acid and dissolved, and the liquid having been deprived of any remaining acid, and reduced to a certain weight by concentration, the process is completed by adding a certain measure of water; so that an acid of definite strength is obtained. Mr. C. Lewis Diehl, jun., has found, in carrying the U. S. process into effect, that the glass funnel covering the capsule almost always breaks through the violence of the reaction, thus causing loss of phosphorus, besides annoyance to the operator. He, therefore, prefers using a French tubulated glass retort. (*Am Journ. of Pharm.*, March, 1867, p. 138.) The U. S. diluted acid has the sp. gr. 1·056; and 100 grains of it are saturated by 23·4 grains of bicarbonate of potassa with

out precipitation. Diluted Phosphoric Acid is defined "Phosphoric acid $3HO$, PO_5, dissolved in water and corresponding to 10 per cent. by weight of anhydrous phosphoric acid PO_5." *Br.* It has the sp. gr. 1·08. "335 grains by weight of it poured upon 180 grains of oxide of lead in fine powder, leave by evaporation a residue, which, after it has been heated to dull redness, weighs 215·5 grains. Six fluidrachms, therefore, correspond to 35·5 grains of anhydrous phosphoric acid ($\frac{1}{2}$ an eq. of PO_5)." *Br.*

The second U. S. formula consists in simply boiling glacial phosphoric acid in water, with the addition of a little nitric acid. By this process the glacial acid, which is monobasic, is converted into the tribasic acid, which is the medicinal phosphoric acid. The nitric acid operates, in this instance, simply by its presence in favouring the change, without itself undergoing decomposition. (See *Acidum Phosphoricum Glaciale*, p. 60.) The proportions of acid and water are so arranged that the diluted acid shall have the same strength as that procured by the first process.

It has been suggested that red phosphorus might be substituted for common phosphorus, as producing the same results, with less danger of explosion; but, when the officinal process is carefully followed in reference to the due dilution and to the use of a moderate heat, there is no danger to be apprehended.

Properties. Diluted phosphoric acid is a colourless, inodorous, sour liquid, acting strongly on litmus, and possessing powerful acid properties. Although evaporated so as to become dense, it is not corrosive like the other mineral acids. Dr. Neubaur found that the strong acid, when pure and warm, was capable of dissolving oxalate of lime. The officinal acid is not precipitated by chloride of barium or nitrate of silver. If precipitates are produced, chloride of barium indicates sulphuric acid or a sulphate; nitrate of silver, muriatic acid or a chloride. Strips of copper or silver are not affected by the acid, showing the absence of nitric acid; it is not coloured by sulphuretted hydrogen, proving the general absence of metals; and albumen produces no precipitate with it, indicating the non-existence of metaphosphoric acid. If carbonate of soda causes a precipitate, phosphate of lime, or some other phosphate insoluble in water, is probably held in solution. It has been supposed that one-tenth of phosphorous acid would render the diluted acid dangerous to life; but experiments go far to show that this was an erroneous opinion, as half a drachm of that acid given to a dog produced no obvious poisonous effect. (See *Am. Journ. of Pharm.*, July, 1858, p. 359.) Phosphorous acid may be detected by testing the medicinal acid with a solution of corrosive sublimate, which will be converted into calomel if this impurity be present. (Pagels, *Chem. Gaz.*, Jan. 15, 1857.)

The following is a table exhibiting the quantity of pure phosphoric acid contained in solutions of different densities, prepared by Mr. John Watts, of London, and published in the *Pharm. Journ. and Trans.*, Oct. 1865, p. 191.

Specific Gravity.	Per-centage.	Specific Gravity.	Per-centage.	Specific Gravity.	Per-centage.	Specific Gravity.	Per-centage.	Specific Gravity.	Per-centage.

Medical Properties and Uses. Diluted phosphoric acid is deemed tonic and refrigerant. It is preferable in point of flavour to the diluted sulphuric acid, and is less apt to disturb the digestive functions. Various properties have been

* British Pharmacopœia. † U. S. Pharmacopœia.

ascribed to it; such as allaying pain and spasm, strengthening the sexual organs, preventing the morbid secretion of bony matter, and correcting phosphatic deposits in the urine. The last two properties are supposed to depend upon its power of dissolving phosphate of lime. It has been recommended in hysteria, diabetes, and in leucorrhœa when the secreted fluid is thin and acrid. Magnus Hus used it with advantage in the first stage of abdominal or petechial typhus. In diabetes Dr. Paris found it to allay the thirst more effectually than any other acid drink. The dose is from twenty drops to a teaspoonful, largely diluted with water.

ACIDUM SULPHURICUM AROMATICUM. *U.S.*, *Br.* *Aromatic Sulphuric Acid. Elixir of Vitriol.*

"Take of Sulphuric Acid *six troyounces;* Ginger, in coarse powder, *a troyounce;* Cinnamon, in coarse powder, *a troyounce and a half;* Alcohol *a sufficient quantity.* Add the Acid gradually to a pint of Alcohol, and allow the liquid to cool. Mix the Ginger and Cinnamon, and, having put them into a percolator, pour alcohol gradually upon them until a pint of tincture is obtained. Lastly, mix the diluted acid and the tincture." *U. S.*

"Take of Sulphuric Acid *three fluidounces*, or 2419 grains by weight; Rectified Spirit *two pints* [Imperial measure]; Cinnamon Bark, in coarse powder, *two ounces* [avoirdupois]; Ginger, in coarse powder, *one ounce and a quarter* [avoird.]. Mix the Sulphuric Acid gradually with the Spirit, add the Cinnamon and Ginger, macerate for seven days, agitating frequently, then filter." *Br.*

Though a certain weight of acid has been substituted for a certain measure in the U. S. process, the result is for all practical purposes the same. The U. S. acid is somewhat stronger than the British. The latter has the sp. gr. 0·927; and "6 fluidrachms [Imp. meas.] or 304·2 grains by weight of it require for neutralisation 830 grain-measures of the *volumetric solution of soda*, corresponding to 10·91 per cent. of anhydrous sulphuric acid. Six fluidrachms [Imp meas.], therefore, correspond to 33·2 grains of anhydrous acid." *Br.*

Properties. Aromatic sulphuric acid is a reddish-brown liquid, of a peculiar aromatic odour, and, when sufficiently diluted, of a grateful acid taste. It has been supposed by some to be a kind of ether, its main ingredients justifying such a suspicion; but the late Dr. Duncan, of Edinburgh, who originally held this opinion, satisfied himself that the alcohol and sulphuric acid, in the proportions here employed, do not generate a single particle of ether. It must, therefore, be viewed merely as sulphuric acid diluted with alcohol, and containing the essential oils of ginger and cinnamon.

Medical Properties and Uses. This valuable preparation, commonly called *elixir of vitriol*, is a simplification of *Mynsicht's acid elixir*. It is tonic and astringent, and affords the most agreeable form of sulphuric acid for administration. It is very much employed in debility with night-sweats, in loss of appetite, and in the convalescence from fevers, especially those of the intermittent type. It is often given in conjunction with cinchona, the taste of which it serves to cover, and the efficacy of which it increases by promoting the solubility of its febrifuge principles. In hæmoptysis and other hemorrhages, when not attended with obvious inflammation, it frequently proves useful by stopping the flow of blood. It has been recommended in epidemic dysentery. (*New Jersey Med. and Surg. Reporter*, ix. 199.) The dose is from ten to thirty drops in a wineglassful of water, repeated two or three times a day. Care must be taken that the teeth are not injured by the acid.

ACIDUM SULPHURICUM DILUTUM. *U.S.*, *Br.* *Diluted Sulphuric Acid.*

"Take of Sulphuric Acid *two troyounces;* Distilled Water *a sufficient quantity* Add the Acid gradually to *fourteen fluidounces* of Distilled Water, and

mix them. Then filter through paper, and pass sufficient Distilled Water through the filter to make the Diluted Acid measure a pint. The sp. gr. of this acid is 1·082." *U. S.*

"Take of Sulphuric Acid 7 *fluidounces* [Imperial measure]; Distilled Water *a sufficiency.* Dilute the Acid with 77 fluidounces of the Water, and when the mixture has cooled to 60° add more Water, so that it shall measure 83½ fluidounces. Or as follows:

"Take of Sulphuric Acid 1350 grains, Distilled Water *a sufficiency.* Weigh the Acid in a glass flask, the capacity of which, to a mark on the neck, is one pint [Imp. meas.], then gradually add Distilled Water until the mixture, after it has been shaken and cooled to 60°, measures a pint [Imp. meas.]. Sp. gr. 1·094. Six fluidrachms [Imp. meas.] or 359 grains by weight require for neutralisation 1000 grain-measures of the *volumetric solution of soda*, corresponding to 10·14 per cent. of anhydrous sulphuric acid. Six fluidrachms, therefore, correspond to 40 grains of the anhydrous acid (one eq. of SO_3)." *Br.*

The direction to filter, in the U. S. process, would be unnecessary were the acid chosen with due attention to the officinal description in the Materia Medica. But as the sulphuric acid of the shops often contains insoluble substances which are precipitated on its dilution, the caution is in practice often necessary to avoid impurity in the preparation. In the old formula a fluidounce of acid was added to thirteen fluidounces of water. The result is very nearly the same.

This preparation is sulphuric acid, diluted to such an extent as to make it convenient for prescription. It is not exactly coincident in strength as directed in the two Pharmacopœias, the U. S. acid being somewhat weaker than the British; but the difference is not so great as to be of practical importance. The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposits a grayish-white powder, which is sulphate of lead, and from which the diluted acid should be poured off. This noxious salt is thus got rid of; but sulphate of potassa, another impurity in the strong acid, still remains. The presence of a little sulphate of potassa will do no harm; but, if it should be fraudulently introduced into the strong acid to increase its specific gravity, its amount may be ascertained by saturating the acid, after dilution, with ammonia, and expelling by a red heat the sulphate of ammonia formed. Whatever sulphate of potassa is present will remain behind.

Medical Properties and Uses. Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in typhoid fevers, and often with advantage. In the convalescence from protracted fevers, it acts beneficially as a tonic, exciting the appetite and promoting digestion. As an astringent, it is employed in colliquative sweats, passive hemorrhages, and diarrhœas dependent on a relaxed state of the mucous membrane of the intestines. In calculous affections attended with phosphatic sediments it is the proper remedy, being preferable to muriatic acid, as less apt, by continued use, to disorder the stomach. Locally it is used as an ingredient in gargles for ulcerated sorethroat and for checking excessive ptyalism, and as a wash for cutaneous eruptions and ill-conditioned ulcers. The dose is from ten to thirty drops, three times a day, in a wineglassful of plain or sweetened water. It is added with advantage to infusions of cinchona, the organic alkalies of which it tends to hold in solution. As it is apt to injure the teeth, it is best taken by sucking it through a quill. It is much less used in the United States than the elixir of vitriol, which possesses nearly the same medical properties. (See *Acidum Sulphuricum Aromaticum.*) An elegant form for giving it is the officinal Compound Infusion of Roses.

In 1851, attention was called by Mr. Buxton, of London, to the remarkable efficacy of diluted sulphuric acid in several forms of diarrhœa, especially choleraic diarrhœa. In October, 1853, Dr. H. W. Fuller, of St. George's Hospital, published a paper in the London *Medical Times and Gazette*, in which he strongly recommends it in choleraic diarrhœa, from his own experience and that of his

friends in more than ninety cases without a single failure. The dose employed was half a fluidrachm, diluted with water, given every twenty minutes in ordinary cases, every quarter of an hour in severe cases. The vomiting, purging, and cramps usually ceased after the third or fourth dose. For bilious diarrhœa the acid is not a suitable remedy.

ACIDUM SULPHUROSUM. *U. S., Br. Sulphurous Acid.*

"Take of Sulphuric Acid *eight troyounces;* Charcoal, in coarse powder, *a troyounce;* Distilled Water *thirty-six fluidounces.* Pour the Acid upon the Charcoal, previously introduced into a matrass, and shake them together. Connect the matrass with a washing bottle, and this, by means of a bent glass tube reaching nearly to the bottom of it, with a two-necked bottle containing the Distilled Water. To the other neck of this bottle attach another bent tube, and let it dip slightly into a solution of carbonate of soda. All the joints having been properly luted, apply heat to the matrass until gas ceases to be evolved, preventing the temperature of the Distilled Water from rising, by means of cold water applied to the bottle containing it. Lastly, pour the Sulphurous Acid into half-pint bottles, which must be well stopped, and kept in a cool place." *U. S.*

"Take of Sulphuric Acid *four fluidounces;* Wood Charcoal, broken into small pieces, *one ounce;* Water *two fluidounces;* Distilled Water *twenty fluidounces.* Put the Charcoal and the Sulphuric Acid into a glass flask, connected by a glass tube with a wash-bottle containing the two fluidounces of Water, whence a second tube leads into an [Imperial] pint bottle containing the Distilled Water, to the bottom of which the gas-delivery tube should pass. Apply heat to the flask until gas is evolved, which is to be conducted through the Water in the wash-bottle, and then into the Distilled Water, the latter being kept cold, and the process being continued until the bubbles of gas pass through the solution undiminished in size. The product should be kept in a stoppered bottle, in a cool place." *Br.*

These are new formulas of the respective Pharmacopœias; sulphurous acid being now for the first time officinally recognised. The processes are essentially the same, and both based upon that of Wittstein The sp. gr. of the U. S. preparation is about 1·035, of the British, 1·04. Of the latter "34·7 grains mixed with an ounce of distilled water and a little mucilage of starch do not acquire a permanent blue colour with the *volumetric solution of iodine* until 1000 grain-measures of the latter have been added." *Br.*

The rationale of the process is simple. When the sulphuric acid (SO_3) and charcoal are heated together, the former gives up an equivalent of its oxygen to the latter, and is thus converted into sulphurous acid gas, which, having been passed first through a wash-bottle containing a little water to absorb impurities, is received into the distilled water, by which it is absorbed until the water becomes saturated. To prevent the escape of the noxious gas into the atmosphere, the excess, which escapes absorption, is in the U. S. process received into a solution of carbonate of soda, and condensed. In the Br. process, the point of saturation is roughly indicated by the bubbles, formed by the escape of the gas from the distilled water, being equal in size to those formed in the wash-bottle. The direction to keep the acid in well-stopped bottles, in a cool place, is necessary in consequence of the strong tendency of the gaseous acid to escape. An incidental advantage of the U. S. process is the production of sulphite of soda.

Prof. F. C. Calvert gives a process for preparing this acid on a large scale, by which he avoids all the inconveniences usually attendant on its manufacture, and has prepared thousands of gallons daily of a saturated solution. It consists in

burning sulphur in a small furnace, and conducting the acid gas, through earthenware tubes, surrounded with water so as to cool them. The gas is then made to ascend through a wooden tube 40 feet high and about 4 feet wide, filled with pumice stone previously washed first with muriatic acid and then with water. A certain amount of water is introduced into the tube from above, which, in its descent, meets and dissolves the gas, and runs out saturated from the bottom of the tube into an air-tight reservoir. (*Pharm. Journ.*, xvii. 512.)

Properties. The officinal sulphurous acid is a nearly saturated solution of sulphurous acid gas. That of the U. S. Pharmacopœia cannot be quite saturated, if the sp. gr. of the two preparations is correctly stated. The pure acid is an irrespirable gas, of a suffocating odour familiar to every one as that of burning sulphur, which is converted into it by combustion. If inhaled in the concentrated state, it proves fatal. It consists of one eq. of sulphur and two eqs. of oxygen (SO_2), has the sp. gr. 2·21, liquefies at 14° F., has a strong acid reaction, extinguishes burning bodies, has the power of bleaching many coloured substances, and has a strong affinity for oxygen, with which it combines in the presence of water, forming sulphuric acid. Water at 65° takes up about 50 volumes of the gas, and the solution has the sp. gr. 1·04. (*Brande and Taylor.*)

Officinal sulphurous acid (*Acidum Sulphurosum*) is a colourless liquid, having the smell of burning sulphur, and a sulphurous somewhat astringent taste. Its sp. gr. as indicated by the Pharmacopœias has been mentioned. When exposed to the air it slowly absorbs oxygen, with the formation of sulphuric acid, and thus acquires a sour taste, and the property of changing vegetable blues to red. It should be entirely volatilized by heat. "When saturated with ammonia, and treated with an excess of chloride of barium, it affords a clear or nearly clear solution on the addition of muriatic acid in excess." (*U. S.*) This shows the absence of sulphuric acid. It decolorizes iodine by forming with it hydriodic acid, and on this fact is based the test of the Br. Pharmacopœia before given.

Medical Properties and Uses. Sulphurous acid has been introduced into use in consequence of its fatal influence upon the lower forms of animal and vegetable life. It is supposed to be thus destructive by its anti-oxygenizing influence; suffocating organic beings by denying them the oxygen necessary to their existence; but it probably acts also by a physiological property independently of its mere chemical effect. It is perhaps by the same property that it prevents fermentation, destroying the microscopic organisms essential to that process. In reference to its parasiticide property, it was brought before the notice of the profession by Dr. Jenner of London; though to Prof. Graham, we believe, belongs the first suggestion of its applicability to such purposes. In cases of sarcinæ ventriculi it may be taken internally; but one of the sulphites, as sulphite of soda, is perhaps preferable for the purpose, as it yields the acid always by decomposition in the stomach. It is more used as an external application, in psora, the different forms of porrigo, trichosis of the scalp, pityriasis versicolor, and the thrush of children; all parasitic affections, either animalcular or cryptogamous, and all of which generally yield to it, if proper care be taken, by previous removal of the scabs or scales, to bring it into contact with the morbific cause. The dose for internal use is a fluidrachm, largely diluted with water. When locally used, it should be diluted with two or three measures of water or of glycerin, and applied as a lotion, or by cloths wet with it, or in the form of cataplasm. Dr. James Dewar, of Kirkaldy, has found very great advantage from the inhalation of sulphurous acid, in the form of the fumes of burning sulphur, in typhus and typhoid fevers, scarlatina, diphtheria, catarrhal fever, hay fever which is checked at once, gout, and rheumatism. (*N. O. Med. and Surg. Journ.*, Jan 1867, p. 523; from *Dub. Med. Press*, Sept. 5, 1866.) W.

ACIDUM TANNICUM. *U. S., Br. Tannic Acid.*

"Take of Nutgall, in fine powder, Ether, each, *a sufficient quantity*. Expose the Nutgall to a damp atmosphere for twenty-four hours, and then mix it with sufficient Ether, previously washed with water, to form a soft paste. Set this

aside, covered closely, for six hours; then, having quickly enveloped it in a close canvas cloth, express it powerfully between tinned plates, so as to obtain the liquid portion. Reduce the resulting cake to powder, and mix it with sufficient Ether, shaken with one-sixteenth of its bulk of water, to form again a soft paste, and express as before. Mix the liquids, and expose the mixture to spontaneous evaporation, until it assumes a syrupy consistence; then spread it on glass or tinned plates, and dry it quickly in a drying closet. Lastly, remove the dry residue from the plates with a spatula, and keep it in a well-stopped bottle." *U. S.*

The British Pharmacopœia has abandoned its former process, and adopted a new one in close conformity with the above, both being essentially the process of Leconnet, which has been substituted, in the existing Pharmacopœias, for that of Pelouze previously employed in both.

While the discarded process yields the tannic acid probably in a somewhat purer state than the present, it is less easy of performance, and much less productive; and the product of the existing formula is sufficiently pure for all practical purposes. The addition of a little alcohol, 8 per cent. for example, to the ethereal menstruum still further increases the product, and, we are informed, is practised to a considerable extent; but we doubt the propriety of this deviation from the officinal directions, as the resulting product may not be in all respects identical with the officinal. There appear to be two colouring principles in galls, one soluble in ether and not in alcohol, the other in alcohol and not in ether. Hence, while the tannic acid, in whichever way procured, is yellowish, that obtained by ether has a greenish tint, while that by the addition of alcohol is slightly brownish. The U. S. process is the same with that proposed by a commission of distinguished French pharmaceutists for the edition of the Codex recently published. In consequence of the mode in which the acid is dried, in thin layers, on tinned or glass plates, and equably exposed to heat above and below, it froths up on the escape of the ether, and concretes in a soft, cellular, friable form, which is strikingly characteristic of the preparation made in strict accordance with the formula.

From a superficial examination of this process, it might appear that the result can be nothing more than an ethereal extract; but it is necessary that the ether employed should contain water, as it is directed to be washed; and yet the quantity of water is so small that it can hardly operate by its mere solvent power. The circumstances attendant upon the process of Pelouze afford the means of a satisfactory explanation, which was first suggested by M. Beral. In this, the powdered galls are submitted to percolation by watered ether, and the liquid which passes divides itself into two layers, a heavier which sinks to the bottom and a lighter which floats upon the surface. It is the heavier which contains the tannic acid, and from which it is obtained by evaporation. The most probable explanation is that ether, water, and tannic acid unite to form a definite compound, in which the affinities are too feeble to resist the tendency of the ether to rise in vapour, and which is, therefore, decomposed by its evaporation. The proportion of the menstruum to the galls is very small, much smaller than would be employed to obtain an extract; and the whole or nearly the whole of both liquids is probably occupied in the formation of the definite compound referred to, thus leaving little or none to act merely as solvents. Hence the exclusion from the resulting acid, in great measure, of the other soluble constituents of the galls; and the slight amount of impurity really present in the acid is probably owing to the action of that small quantity of the menstruum not occupied in forming the liquid compound. Opinion is not altogether united in this explanation; but it is that which appears to the author best to account for the phenomena of the case. It has been stated that the tannic acid, obtained by either of the officinal processes, has a more or less yellowish tint. From this, according to F. Kummel, it may be freed by the percolation, through recently ignited animal charcoal, of its solution in a mixture of ether and alcohol. It has, too, a slight odour, which, according to Prof. Procter, is derived from a volatile odorous prin-

ciple existing in galls, which he has succeeded in separating from the acid by the action of benzole. From 30 to 35 per cent. of tannic acid is obtained from galls by Pelouze's method; while that of Leconnet is said to yield 60 per cent.*

The term *tannin* was originally applied to a principle or principles existing in many vegetables, having a very astringent taste, and the properties of producing a white flocculent precipitate with solution of gelatin, and a black precipitate with the salts of sesquioxide of iron. As obtained, however, from different plants, it was found to exhibit some difference of properties; and chemists have recognised two kinds, one existing in oak bark, galls, &c., distinguished by producing a bluish-black precipitate with the salts of sesquioxide of iron, and the other existing in Peruvian bark, catechu, &c., and characterized by producing a greenish-black or dark-olive precipitate with the same salts. The former is the one which has received most attention, and from an examination of which the characters of tannin have generally been given. It is the substance described in this article. It will probably be found that the latter is essentially distinct from the tannin of galls, and different in different vegetables. One striking peculiarity of the tannin of galls is its facility of conversion into gallic acid, which is wanting in the other varieties. Since the publication of the experiments of M. Pelouze in relation to tannin, this substance has been universally admitted to rank with the acids, and is now, therefore, denominated *tannic acid.* The ordinary variety procured from galls is called, for the sake of distinction, by some *gallotannic acid,* and by others *quercitannic acid.* According to Pettenkofer, it is found only in perennial plants, indicating some relation to the production of woody fibre. (*Buchner's Neues Repert.*, iii. 74–76.)

Properties. Pure tannic acid is solid, uncrystallizable, white or slightly yellowish, inodorous,† strongly astringent to the taste without bitterness, very soluble in water, much less soluble in alcohol and ether, especially when anhydrous, and insoluble in the fixed and volatile oils. It may be kept unchanged in the solid state; but its aqueous solution, when exposed to the air, gradually becomes turbid, and deposits a crystalline matter, consisting chiefly of gallic acid. During the change, oxygen is absorbed, and an equal volume of carbonic acid disengaged. But, according to M. E. Robiquet, this change does not always take place, and, when it does happen, is ascribable to the presence of pectase in the tannin. (See *page* 958.) If the solution of tannic acid be boiled for a long time, the pectase loses its property of acting as a ferment, and the solution may be kept indefinitely without change. (*Journ. de Pharm.*, Avril, 1853, p. 246.)

Exposed to heat, tannic acid partly melts, swells up, blackens, takes fire, and burns with a brilliant flame. Thrown on red-hot iron, it is entirely dissipated. Its solution reddens litmus, and it combines with most of the salifiable bases. It forms with potassa a compound but slightly soluble, and is, therefore, precipitated by this alkali or its carbonates from a solution which is not too dilute, though a certain excess of alkali will cause the precipitate to be redissolved. Its combination with soda is much more soluble; and this alkali affords no precipitate, unless with a very concentrated solution of tannic acid. With ammonia its relations are similar to those with potassa. Baryta, strontia, lime, and magnesia, added in the state of hydrates, form with it compounds of little solubility. The same is the case with most of the metallic oxides, when presented, in the state of salts, to a solution of the tannate of potassa. Many of the metallic salts are precipitated by tannic acid even in the uncombined state, especially those of lead, copper, silver, uranium, chromium, mercury, teroxide of antimony, and protoxide of tin. With the salts of sesquioxide of iron it forms a black precipitate, which is a compound of tannic acid and the sesquioxide,

* We are informed that Mr. H. R. Bowman, of Philadelphia, in a yet unpublished thesis, gives 80·07 as the percentage of tannic acid he had obtained from selected galls, while from white galls he had got but 30·72 per cent. (*Note to the thirteenth edition.*)

† Commercial tannic acid often has a decided odour, which Prof. Procter, after a practical investigation, believes to be owing chiefly to the presence of the odorous principle of the galls, though sometimes to matter derived from the ether with which it is prepared. (*Am. Journ. of Pharm.*, Jan. 1865, p. 53.)

and is the basis of ink. It does not disturb the solutions of the pure salts of protoxide of iron. Several of the alkaline salts precipitate it from its aqueous solution, either by the formation of insoluble compounds, or by simply abstracting the solvent.

Tannic acid unites with all the vegetable organic alkalies, forming compounds which are for the most part of a whitish colour, and but very slightly soluble in water; though they are soluble in the vegetable acids, especially the acetic, and in alcohol, and in this latter respect differ from most of the compounds which tannic acid forms with other vegetable principles. On account of this property of tannic acid, it has been employed as a test of the vegetable alkalies; and it is so delicate, that it will throw down a precipitate from their solution, even when too feeble to be disturbed by ammonia.

It has an affinity for several acids, and when in solution affords precipitates with the sulphuric, nitric, muriatic, phosphoric, and arsenic acids, but not with the oxalic, tartaric, lactic, acetic, or citric. The precipitates are considered as compounds of tannic acid with the respective acids mentioned, and are soluble in pure water, but insoluble in water with an excess of acid. Hence, in order to ensure precipitation, it is necessary to add the acid in excess to the solution of tannic acid. Strecker, however, denies that the precipitates are compounds of the tannin with the acid, and maintains that they are merely tannin imbued with free acid. (*Chem. Gaz.*, no. 287, p. 370.)

When tannic acid, iodine, and water are mixed, a reaction takes place, by which the water is decomposed; its hydrogen forming with the iodine hydriodic acid, which combines with a portion of the tannic acid and remains in solution; while the oxygen of the water combines with another portion of the tannic acid, to form a compound, which, being insoluble, is precipitated. The iodized solution thus obtained is capable of dissolving more iodine, and holding it in permanent solution, however much diluted. (Socquet and Guilliermond, *Journ. de Pharm.*, xxvi. 280.)

Tannic acid precipitates solutions of starch, albumen, and gluten, and forms with gelatin an insoluble compound, which is the basis of leather.

Its ultimate constituents are carbon, hydrogen, and oxygen; and its formula, according to Liebig, is $C_{18}H_8O_{12}$ or $C_{18}H_5O_9 + 3HO$. Mulder, however, from recent investigations, considers it isomeric with gallic acid, and gives its formula $C_{23}H_9O_{17} + HO$. Strecker looks upon it as a compound of gallic acid and grape sugar, the latter of which is destroyed in the spontaneous change that moistened galls undergo by time. (See *Acidum Gallicum*, page 958.) He gives as its formula $C_{54}H_{19}O_{31}$ for the anhydrous acid, which, by the addition of 3 eqs. of water, becomes the hydrated acid $C_{54}H_{22}O_{34}$, differing from Liebig's by 2 eqs. of water. (*Chem. Gaz.*, no. 287, p. 370.) M. E. Robiquet denies the complex nature ascribed to tannic acid by Strecker, and maintains that, when transformed into gallic acid by the pectic ferment or by sulphuric acid, it is simply by a molecular change, and not by the destruction of one of its constituents. (*Journ. de Pharm.*, xxvi. 31.) But, whether consisting of glucose and gallic acid, or simply resolvable by certain agencies, through a new arrangement of its molecules, into these substances, it will equally rank among the glucosides; differing in this respect essentially from the varieties of tannic acid which precipitate the salts of iron greenish-black, as the tannin of rhatany and catechu.*

Medical Properties and Uses. Tannic acid, being the chief principle of vegetable astringents, is capable of exerting on the system the same effects with this class of medicines, and may be given in the same complaints. It has an advantage over the astringent extracts in the comparative smallness of its dose, which renders it less apt to offend an irritable stomach. In most of the vege-

* Various plans have been proposed of estimating the quantity of tannic acid, which is an object of importance to tanners, as enabling them to judge of the value of their tanning materials; but on this point we must content ourselves, from want of space, with referring to the *Am. Journ. of Pharm.* (Sept. 1859, p. 427; March, 1861, p. 164; Nov. 1863, p. 519; and July, 1864, p. 314). See also a paper by Mr. John Watts in the *Pharm. Journ. and Trans.* (March, 1867, p. 515).

table astringents, it is associated with more or less bitter extractive, or other principle which modifies its operation, and renders the medicine less applicable than it otherwise would be to certain cases, in which there is an indication for pure astringency without any tonic power. Such is particularly the case in the active hemorrhages; and tannic acid, in its separate state, is in these cases preferable to the native combinations in which it ordinarily exists. Dr. Porta, an Italian physician, employed it with great success in the treatment of uterine hemorrhage, and published the results of his experience in 1827. M. Cavalier afterwards used it successfully in the same complaint, and found it effectual also in a case of bleeding from the rectum. It is, without doubt, a useful remedy in most forms of hemorrhage, after a sufficient reduction of arterial action by depletory measures. In diarrhœa it is probably more beneficial than ordinary astringents, as less liable to irritate the stomach and bowels. It has been found beneficial in colliquative sweats, in cases of chronic catarrh with excessive and debilitating expectoration, in the advanced stages of hooping-cough, and in cystirrhœa. The dose for ordinary purposes is from two to five grains, but in urgent cases it may be increased to ten grains. The only disadvantage which has been experienced from it, when taken in excess, is obstinate constipation. It has been used with advantage, by Dr. P. Garnier, in very large doses, in the dropsy of Bright's disease. He gave from half a drachm to a drachm, in divided doses, through the day, and found its curative influence, beginning on the second day, to be manifested by copious diuresis with a return of the urine to a healthy state, by perspiration, ready alvine evacuation, and a restoration of appetite, without any unpleasant effect. (*Arch. Gén.*, Janv. 1859, p. 36.) Locally, it may be used for all the purposes to which galls or other vegetable astringents are applicable; as for hemorrhages, relaxation of the uvula, chronic inflammation of the fauces, diphtheria, toothache, aphthæ, excessive salivation, leucorrhœa, gleet, gonorrhœa, flabby and phagedenic ulcers, piles, chilblains, &c. As a wash it may be used in solution, in the proportion of five grains to a fluidounce of water. A Belgian surgeon, M. Hairion, recommends a strong solution, made in the proportion of one part of tannic acid to three of distilled water, for application to various ophthalmic affections; as acute and chronic inflammation, ulcers and specks on the cornea, swelling of the conjunctiva, &c. (*Journ. de Pharm.*, xviii. 449.) An ointment may be made from it by rubbing two scruples first with twenty minims of water into a paste, and then with an ounce of lard. A solution in glycerin, which dissolves it freely, has been recommended by Dr. Wm. Bayes, of Brighton, England, as a powerful styptic, and an excellent local application in diseases of the mucous surfaces requiring an astringent impression. In affections of the rectum it may be used in the form of a suppository. In diseases of the uterus it has been recommended in the form of a cylindrical pencil about an inch long and two lines thick, made with 4 parts of the acid to 1 part of tragacanth, with a little crumb of bread to give the mixture due flexibility. (*Journ. de Pharm.*, Fév. 1, 1860, p. 128.)

Dr. B. W. Richardson, of London, has given the name of *styptic colloid* to a liquid prepared by himself, consisting of ether saturated with tannic acid and a colloidal substance, such as xyloidine or gun-cotton. The preparation of it is slow, but not difficult. First, tannin, as pure as can be obtained, is digested in absolute alcohol for several days; then pure ether is added until the thick alcoholic mixture is rendered quite fluid; and, finally, the colloidal substance is introduced until it ceases readily to dissolve. When applied on wounded or abraded surfaces, it soon loses the ether and alcohol, and a firm coating is left, in which, besides the tannin and colloidal substance, are the blood and secretions from the surface, with albumen coagulated, forming a covering for the part by which the air is excluded. The liquid is applied by means of a camel's-hair brush, and sometimes by means of cotton saturated with it, to the edges of wounds closed by stitches, to ulcerated surfaces, cancerous sores, necrosis, and bleeding parts. If it be desired to make a special impression on the diseased surface, as by carbolic acid, creasote, iodine, morphia,

&c., the agent may be incorporated with the styptic fluid (*Pharm. Journ. and Trans.*, July, 1867, p. 29; also *Am. Journ. of Pharm.*, July, 1867.)

Given largely to a dog, tannic acid caused the urine to become dark-brown and opaque; and the secretion gave evidences of the presence of gallic and pyrogallic acids. (*Chem. Gaz.*, no. 136, p. 231.) Hence it is probable that, when absorbed, it undergoes a change into one or both these acids, and that it is through these that it produces its effects on the system.

ACIDUM VALERIANICUM. *U. S. Valerianic Acid.*

"Take of Valerianate of Soda, in coarse powder, *eight troyounces;* Sulphuric Acid, Water, each, *a sufficient quantity.* To the Valerianate of Soda add, first, three fluidounces of Water, and then three troyounces and a half of Sulphuric Acid. Mix them thoroughly, and from the mixture, after standing, separate the oily acid liquid which rises to the surface. Agitate this repeatedly with small portions of Sulphuric Acid until its specific gravity is reduced below 0·950. Then introduce it into a retort, and distil nearly to dryness, rejecting the distillate so long as it has a specific gravity above 0·940, and keeping the remainder for use. The rejected portion of the distillate, after agitation with Sulphuric Acid, may be returned to the retort during the progress of the distillation." *U. S.*

The object of this process is merely to procure valerianic acid in a state adapted for the preparation of valerianate of ammonia. The sulphuric acid, uniting with the soda of the valerianate of soda, separates the valerianic acid, which rises to the surface with the appearance of an oil. In this state it is combined with more than one eq. of water, and as it is the monohydrated acid that is wanted, the direction is given to agitate it with sulphuric acid which deprives it of the excess of water. It is now distilled in order to separate any sulphuric acid and water that may be mixed with it. The process is that of Mr. B. J. Crew, published in the *Am. Journ. of Pharm.* for March, 1860 (p. 109). Mr. F. C. Musgiller, of Brooklyn, N. Y., states that the acid cannot be obtained by the U. S. process of a sp. gr. so low as 0·933 with ordinary sulphuric acid, and suggests that 0·935 be adopted as the officinal standard; as acid of this strength is equally well adapted for the preparation of the valerianates, for which it is used. Mr. Musgiller proposes some modifications of the U. S. process which appear to be judicious; but which must be submitted to the test of experiment before being officinally adopted. (See *Am. Journ. of Pharm.*, Jan. 1869, p. 83; also *Proceed. of Am. Pharm. Assoc.*, 1868.)

For modes of preparing valerianic acid from the oil and roots of valerian, the reader is referred to the article on Valerian at *page* 881. It is prepared also from fusel oil (amylic alcohol) by reaction with a mixture of bichromate of potassa and sulphuric acid, as the first step in the preparation of valerianate of soda. (See *Sodæ Valerianas*, Part II.)

Valerianic acid received its name from having been found in the oil distilled from the root of Valeriana officinalis. It is sometimes called also *valeric acid.* It was first obtained in 1817 by Chevreul from the oil of the dolphin, and received the name of *delphinic acid*, which, however, upon the discovery of its identity with the acid afterwards obtained by Pentz from valerian, was superseded by its present title. It has been obtained also from the bark and fruit of Viburnum opulus, the sap-wood of the European elder (Sambucus nigra), the root of Angelica Archangelica, and from various organic products whether of the vegetable or animal kingdom.

Properties. Valerianic acid is a colourless liquid, of an oily consistence, a repulsive odour, recalling, however, that of valerian, and a pungent, sour, acrid, disagreeable taste. Its sp. gr. is variously given from 0·930 at 55° to 0 944 at 50°. (*Gmelin.*) As stated in the U. S. Pharmacopœia, it is 0·933. It remains liquid at 8° below zero, and boils at 270° F. (*Trommsdorff.*) It is soluble in 30 parts of cold water, and when agitated with water takes up about 20 per cent., without

losing its oily consistence, and rises to the surface of the liquid. Alcohol and ether mix with it in all proportions. It is very soluble in strong acetic acid, and dissolves camphor and some resins. (*Trommsdorff.*) It forms salts with the alkalies, and reddens litmus paper strongly, but the blue colour gradually returns in a warm place. Its composition is represented by $C_{10}H_{10}O_4$; but it is supposed to bear to fusel oil a similar relation with that between acetic acid and alcohol. Thus, the compound radical *amyl* ($C_{10}H_{11}$) uniting with one eq. of oxygen and one of water forms *fusel oil* ($C_{10}H_{11}O+HO$), which, by the loss of two eqs. of hydrogen and the gain of two of oxygen, becomes monohydrated valerianic acid ($C_{10}H_9O_3+HO$). In this state the acid is capable of uniting with two additional eqs. of water, forming the terhydrated acid ($C_{10}H_9O_3+3HO$), or, if the eq. of water in the dry acid be considered as constitutional, the bihydrated acid ($C_{10}H_{10}O_4+2HO$). This has a much milder taste than the dry or monohydrated acid, and at the same time somewhat saccharine. According to Chiozza, the anhydrous acid ($C_{10}H_9O_3$) may be prepared by treating valerianate of potassa with oxychloride of phosphorus. (*Gmelin's Handbook*, xi. 37.) The U. S. Pharmacopœia gives the following tests of the officinal acid. "A solution of Valerianic Acid in 50 parts of hot water, saturated with hydrated carbonate of zinc, yields a liquid, which, when filtered and evaporated to 10 parts and cooled, affords white pearly crystals of valerianate of zinc. The mother-water, drained from these crystals, should not yield, by further evaporation and cooling, a salt crystallizing in six-sided tables, and very soluble in water. When the Acid is added to a concentrated solution of acetate of copper, the transparency of the solution is not disturbed." The former of the last two tests indicates the absence of acetic, the latter of butyric acid.

Medical Properties and Uses. In the state in which it is obtained by this process, valerianic acid has not been used as a medicine. The acid distilled from the oil or root of valerian has been employed in nervous affections, and possesses properties similar to those of valerian. According to Landerer, the acid artificially produced does not operate therapeutically so satisfactorily as the native product. The dose would probably be about the same as that of the oil of valerian. It may be given in sweetened water.

ACONITIA. *U. S., Br.*

Aconitia.

"Take of Aconite Root, in moderately fine powder, *forty-eight troyounces;* Diluted Sulphuric Acid *a fluidounce and a half;* Alcohol, Stronger Water of Ammonia, Stronger Ether, Distilled Water, each, *a sufficient quantity.* Digest the powder in eight pints of Alcohol, in a close vessel, at the temperature of 120°, for twenty-four hours. Introduce the mixture into a cylindrical percolator, and gradually pour Alcohol upon it until twenty four pints of liquid have slowly passed. Distil off the alcohol from the filtered liquid until this is reduced to the measure of a pint. Then add to the concentrated liquid a pint of Distilled Water, to which has been added the Diluted Sulphuric Acid, and mix thoroughly. Remove from the liquid the fixed oil and resin which separate on standing, and evaporate it to four fluidounces. When the liquid has cooled, pour it into a glass-stoppered pint bottle, and wash it, by agitation and decantation, with six fluidounces of Stronger Ether, to remove the remainder of the fixed oil and resin. Now add Stronger Water of Ammonia until, after agitation, it remains in slight excess. Next, treat the resulting mixture with six fluidounces of Stronger Ether, and, having closed the bottle, agitate briskly for a few minutes. Allow the liquid to stand until it separates into two layers, the lighter being an ethereal solution of Aconitia. Decant this carefully, and treat what remains, twice successively, with the same quantity of Stronger Ether, decanting each time as before. Mix the several ethereal solutions in a porcelain

capsule, and allow the mixture to evaporate spontaneously to dryness. Lastly, reduce the dry residue to powder, and keep it in a well-stopped bottle." *U. S.*

"Take of Aconite Root, in coarse powder, *fourteen pounds* (avoird.); Rectified Spirit, Distilled Water, Solution of Ammonia, Pure Ether, Dilute Sulphuric Acid, of each, *a sufficiency*. Pour upon the Aconite Root three gallons of the Spirit, mix them well, and heat until ebullition commences; then cool, and macerate for four days. Transfer the whole to a displacement apparatus, and percolate, adding more Spirit, when requisite, until the root is exhausted. Distil off the greater part of the spirit from the tincture, and evaporate the remainder over a water-bath until the whole of the alcohol has been dissipated. Mix the residual extract thoroughly with twice its weight of boiling Distilled Water, and, when it has cooled to the temperature of the atmosphere, filter through paper. To the filtered liquid add Solution of Ammonia in slight excess, and heat them gently over a water-bath. Separate the precipitate on a filter, and dry it. Reduce this to coarse powder, and macerate it in successive portions of the Pure Ether with frequent agitation. Decant the several products, mix, and distil off the ether until the extract is dry. Dissolve the dry extract in warm Distilled Water acidulated with the Sulphuric Acid; and, when the solution is cold, precipitate it by the cautious addition of Solution of Ammonia diluted with four times its bulk of Distilled Water. Wash the precipitate on a filter with a small quantity of cold Distilled Water, and dry it by slight pressure between folds of filtering paper." *Br.*

The process of the U. S. Pharmacopœia, which is a modification of that of Headland, published in a note in a preceding edition of the U. S. Dispensatory, was substituted for the former U. S. process, because, in consequence of the amount of water employed, and the use of animal charcoal, which absorbed much of the alkaloid, that formula had proved unproductive. In the present, the powdered root is exhausted with alcohol by percolation, most of the alcohol distilled off, and the residue treated with very dilute sulphuric acid, by which the native salt is converted into the sulphate. After the removal of the resinous and oily matters that separate, the solution of the sulphate is concentrated, and washed with ether, which, without dissolving the sulphate, which is insoluble in that menstruum, removes the remaining oil and resin. The addition of ammonia now decomposes the sulphate, separating the alkaloid, which in this state is dissolved out by repeated agitation with ether; and the process is completed by mixing the ethereal solutions, and allowing them to evaporate spontaneously. The points in which this process differs from that of Headland, are the use of percolation to exhaust the root instead of boiling with alcohol, and the washing with ether before the addition of ammonia, by which the resin and colouring matter are removed. The latter modification originated in a suggestion of Prof. Procter in a communication to the *Am. Journ. of Pharm.* (March, 1861, p. 102).

In the British process, the root is exhausted with alcohol by a combination of maceration and percolation, which experience has shown to be unnecessary; the resulting tincture is wholly deprived of its alcohol by distillation and evaporation; and the residue thoroughly exhausted by boiling water. The solution thus obtained is treated with ammonia; and the precipitate, which contains the alkaloid, having been dried and powdered, is exhausted by ether. Lastly, the impure aconitia obtained by distilling off the ether, is purified by solution in water acidulated with sulphuric acid, and precipitation by ammonia. This process was given to the Pharmacopœia Committee of the British Council by a manufacturer who had been in the habit of preparing the alkaloid. (*Garrod.*)*

* A process has recently been published by M. E. Hottot, of France, which is believed by the author to yield the alkaloid pure. The powdered root is macerated for eight days in alcohol of 85°; the liquid is separated by percolation; slaked lime is added, and the mixture shaken from time to time; the liquid is filtered, precipitated by a slight excess of sulphuric acid, and evaporated to a syrupy consistence; twice or three times its weight of water is added to the residue, the mixture allowed to rest, and the green oil which rises to the surface and solidifies at 68° F. removed; the liquid having been passed through a moist filter to separate the last portion of oil, is treated with ammonia, and raised to the

It is highly probable that more or less of the aconella discovered by the Messrs. Smith of Edinburgh in aconite root, and now believed to be identical with narcotina, is contained in most of the aconitia of commerce. It appears to us that it must contaminate the product of the British process, and, if not present in the U. S. aconitia, must have been removed by the preliminary washing with ether. If great care is taken, in the preparation of aconitia, to avoid the slightest excess of sulphuric acid, beyond what is necessary for the solution of this alkaloid, the aconella will be left behind; and on the same principle it may be separated from aconitia when existing in it. Should a mixture of the two be decolorized by animal charcoal, the aconitia would be liable to be absorbed, and the aconella to be left. (Messrs. Smith, *Pharm. Journ.*, Jan. 1864, p. 319.) Whichever process is used, care should be taken not to employ the ammonia in great excess, as it diminishes the product probably by dissolving the aconitia.*

Properties. As procured by either of the officinal processes aconitia is slightly coloured; but when pure it is perfectly white. As generally obtained it is amorphous; but it would seem to be capable of crystallization; for we are told that a specimen of aconitia in perfectly defined large crystals was contributed by Mr. Morson, of London, to the International Exhibition of 1862. (Groves, *Pharm. Journ. and Trans.*, 2d ser., viii. 121.)† When obtained by precipitation from a watery solution of its salts, it is in the form of a hydrate, containing 25 per cent. of water; but it yields its water when heated, and may be obtained anhydrous by the spontaneous evaporation of its solution in ether, or by precipitation by the alkalies from a boiling solution of its salts. In this case it forms a compact coagulum. (*Hottot.*)

Aconitia probably exists in the plant combined with a vegetable acid, forming a soluble salt. It is inodorous, and of a bitter and acrid taste, producing a benumbing impression on the tongue. It is unalterable in the air, and fusible by a gentle heat. It has been usually considered as not volatilizable, being decomposed at a high temperature, with the escape of ammonia, and by a continuance of the heat entirely dissipated. This statement, however, is contradicted by the results obtained by Mr. Guy, who found it to melt at 140°, and

boiling point; the aconitia, which is deposited in a compact mass, and contains much resin, is washed, and treated with pure ether, and the ethereal solution allowed to evaporate; the residue is dissolved in water acidulated with sulphuric acid, and precipitated by ammonia; the coagulum which forms is collected on a filter, dried, and dissolved in ether; the ethereal solution is evaporated to dryness, the residue treated with a very little dilute sulphuric acid, and the solution precipitated by dilute solution of ammonia added drop by drop. The first portion deposited, being coloured, is separated, and the precipitation continued till the ammonia is in slight excess. The precipitate now formed is washed until freed from ammoniacal odour, and dried at a low temperature. Ten kilogrammes (about 26 lbs. troy) of the root yield a mean product of from 4 to 6 grammes (℥i to ℥iss) of the alkaloid, which is perfectly white. (*Ann. de Thérap.*, 1864, p. 46.)—*Note to the twelfth edition.*

* The root of *Aconitum ferox*, from the E. Indies, is preferable for procuring the alkaloid, in consequence of its greater yield. A specimen of this, which we have had the opportunity of examining, was in single roots, fusiform, from two and a half to three and a half inches long, from half an inch to an inch and a half thick at the thickest part near the top, gradually tapering to a point, unequally wrinkled from drying, of a dark-brown colour externally, yellowish internally, hard, with a shining wax-like fracture, and the characteristic taste of the aconites in a high degree. (*Note to the tenth edition.*)

† As Dr. Guy and Mr. Waddington, though, with the aid of the process of micro-sublimation, one or both obtained crystalline sublimates of all the alkaloids with one or two exceptions, and even succeeded in subliming aconitia, were unable to obtain a crystalline sublimate of this alkaloid (*Pharm. Journ.*, July, 1867, p. 11), the inference is fair that aconitia, so far as at present known, is essentially uncrystallizable. This is not a matter of indifference; for specimens from Germany, sold in the London market as aconitia, have been partially crystallizable, and the inference is that they were contaminated with another alkaloid of aconite, the aconella of the Messrs. Smith, for example, which is at the same time readily crystallizable, and wholly destitute of the peculiar physiological properties of aconitia; and it is difficult to resist the suspicion, that the aconitia of Mr. Morson, mentioned in the text, owed its crystalline character to the same cause. That Dr. Groves succeeded in crystallizing certain salts of aconitia is no proof that the alkaloid itself is crystallizable. (*Note to the thirteenth edition.*)

to sublime unchanged at about 400°. (*Pharm. Journ. and Trans.*, Feb. 1868, p. 374.) It is sparingly soluble in water, requiring for solution 150 parts of cold and 50 of boiling water. (*Phillips.*) Alcohol, ether, and chloroform dissolve it readily. It restores the blue colour of litmus reddened by acids, and neutralizes the acids, forming crystallizable salts. The solution of these salts produces a white precipitate with bichloride of platinum, a yellowish with terchloride of gold, and a yellowish-brown with free iodine. Aconitia is precipitated from the solution by the caustic alkalies, but not by carbonate of ammonia, or the bicarbonates of potassa and soda. (*Br.*) Its received formula is $C_{60}H_{47}NO_{14}$. A spurious substance has sometimes been sold under the same name, which is nearly or quite inert; and at best the alkaloid is apt to be of uncertain strength, as found in the shops. This can be accounted for, now that it is known that aconella must have largely contaminated the alkaloid as procured by the processes used, and sometimes may have been the chief ingredient.

Medical Properties and Uses. This vegetable principle exercises a powerful influence over the animal economy. One-fiftieth of a grain dissolved in alcohol destroyed a sparrow in a few minutes; and the same quantity, administered to an elderly female, is said to have nearly proved fatal. Dr. Garrod has repeatedly known large dogs to be killed by the 50th of a grain; more than half an hour usually elapsing before death. (*Med. Times and Gaz.*, Feb. 1864, p. 146.) In a case of poisoning by aconitia, recorded by Dr. Golding Bird, though two grains and a half were taken, the patient ultimately recovered. But, as vomiting almost immediately ensued, there is reason to believe that much of the poison was thus discharged from the stomach. Besides extreme general prostration, indicated by a cold pale surface, and a scarcely perceptible action of the heart, the prominent symptoms were convulsive vomiting, recurring every minute or two, and fearful spasms of the throat, resembling those of hydrophobia, upon any attempt at swallowing. There was no paralysis, the pupils were sensible to light, and the intellect remained perfectly clear. The remedies were the hot bath, mustard to the epigastrium, and enemata of oil of turpentine, laudanum, and nutriment. (*Lond. Med. Gaz.*, Jan. 1847.) Dr. Van Praag found, in his experiments with aconitia on the lower animals, that it lessens cerebral power, paralyzes the nerves of voluntary motion, dilates the pupil, retards respiration, is uncertain in its influence on the pulse, and destroys life either suddenly by asphyxia, or more slowly by exhaustion.

The observations of M. Hottot, from experiments on himself, are deserving of notice, from the great care with which they appear to have been made. From doses gradually increased to 3 milligrammes (·046 gr.), M. Hottot experienced, immediately, over the whole mucous membrane of the mouth, a sensation of acrimony and heat, which rapidly extended to the throat, and somewhat later to the stomach. This feeling became more and more intense, with burning and numbness of the lips, tongue, pharynx, and a profuse salivation. To these local effects were soon added general phenomena, at first uneasiness, weakness, heaviness of head, then nausea and frequent yawning, oppression, marked muscular debility, tingling over different parts of the body, but especially in the face and limbs, and a slightly excited pulse. After a time the weakness increased, headache and often lancinating pains of the face supervened, and the nausea was attended with vomiting. These were followed by increased muscular prostration, still more manifest tinglings, numbness of the limbs, swollen features, reduced pulse, difficult breathing, painful burning in the throat, and copious sweats. Later still, general prostration came on, the least effort produced exhaustion, the breathing became deep and slow, and the pulse was sensibly lowered. There was no sleep, and the pupil was moderately dilated; but the intelligence remained sound. These symptoms continued from ten to sixteen hours, and were then gradually relieved, the most persistent being irritation of the throat, heaviness of head, and general lassitude. The effects were precisely those of aconite itself. Aconitia is little used internally as a remedy. M. Hottot, however, has employed it to obtain the effects of aconite,

giving it in the form of pills, each containing the fifth of a milligramme ($\frac{1}{3\,1\,3}$ of a grain), or in a tincture containing one-sixteenth of a grain in the drachm. The quantity taken daily was of the pills from 2 to 10, of the tincture from 10 to 40 drops, in divided doses. Gubler, who seems familiar with the action of this alkaloid, states that it is rarely proper to exceed the quantity in a day of two milligrammes, taken in four doses, or about the $\frac{1}{1\,3\,0}$ of a grain for a dose. (*Ann. de Thérap.*, 1865, p. 82.) But the internal use of so powerful a medicine is hazardous, and should not, we think, be encouraged, as very slight errors might lead to the most serious effects; and we can quite as conveniently use the tincture.

Dr. Turnbull was the first to recommend the external use of aconitia; and his favourable report has been abundantly confirmed by others. By this writer it is said to produce in the skin a sensation of heat and prickling, followed by numbness; and the effect continues, according to the quantity applied, from two to twelve hours or more. He found it not to act as a rubefacient, or at least but slightly so. Applied much diluted and in minute quantity to the eye, it causes contraction of the pupil, with an almost intolerable sense of heat and tingling. Dr. Turnbull employed it with benefit in neuralgia, gout, and rheumatism. He recommends it either in alcoholic solution, in the proportion of a grain to a fluidrachm, or in the form of an ointment, made by rubbing two grains of the alkaloid first with six drops of alcohol, and then with a drachm of lard. These proportions are sufficiently large to begin with, but may be gradually increased to four or five, or even eight grains to the drachm. The application should be made by friction over the part affected, to be continued till the peculiar sensation above described is produced, and may be repeated three or four times, or more frequently, during the day. No good can be expected unless the sensation alluded to be experienced in a greater or less degree. Care should be taken not to apply the medicine to an abraded surface, or to a mucous membrane, for fear of dangerous constitutional effects. It has gradually come into extensive use, and has the advantages, as an external remedy, over other preparations of aconite, of greater neatness and precision.

Off. Prep. Unguentum Aconitiæ, *Br.* W

ÆTHEREA.

Ethers.

Ethers are peculiar, fragrant, sweetish, very volatile, and inflammable substances, generated for the most part by the action of acids on alcohol. Their composition varies with the acid employed in their formation. Sometimes this merely acts as a chemical agent on the alcohol, without entering into the composition of the ether generated; in which case the ether may be supposed to consist, according to the views that may be adopted of its constitution, either of ethylen (etherine), C_4H_4, and water, or of ethyl, C_4H_5, and oxygen. In other instances, the ethylen theory being admitted for the present, the acid employed unites with ethylen and water (the ether just mentioned), or with ethylen only. On the basis of these differences of composition, the medicinal ethers may be divided into three kinds: 1. those consisting of ethylen and water; 2. those consisting of an acid, ethylen, and water; and 3. those composed of an acid and ethylen only. Hydric ether is the only medicinal ether of the first kind, nitrous ether is an example of the second, and muriatic ether of the third. In medicine, the hydric and nitrous ethers, and their modifications, are those most commonly employed; though occasionally the muriatic and acetic have been used. In conformity with the new arrangement of the U. S. Pharmacopœia, we shall consider under this heading only the ethers themselves, transferring to the Spirits those Preparations which are formed by a mixture of the ethers and alcohol, and officinally denominated Spirits; as the *Spirit* and *Compound Spirit of Ether*, and the *Spirit of Nitrous Ether*.

Ethers, from their extreme inflammability, should never be decanted in the vicinity of flame. Hence it is prudent not to pour them out near a lighted candle. They should be kept in accurately stopped bottles, in a cool place; otherwise they are liable to considerable loss by evaporation. B.

ÆTHER. *U. S., Br.* ÆTHER SULPHURICUS. *Ed., Dub. Ether. Sulphuric Ether. Hydric Ether. Hydrate of Ethylen. Oxide of Ethyl.*

"Take of Stronger Alcohol *six pints;* Sulphuric Acid *thirty-six troyounces;* Potassa *three hundred and sixty grains;* Distilled Water *three fluidounces.* To two pints of the Alcohol, contained in a six-pint tubulated retort, gradually add the Acid, stirring constantly during the addition. By means of a cork fitted to the tubulure, adapt a long funnel-shaped tube, with the lower end drawn out so as to form a narrow orifice, and reaching nearly to the bottom of the retort, and also a thermometer tube, graduated from 260° to 300°, with its bulb reaching to the middle of the liquid. Having placed the retort on a sand-bath, connect it with a Liebig's condenser, and this with a well-cooled receiver. Then raise the heat quickly until the liquid boils, and attains a temperature between 266° and 280°. By means of a flexible tube, connected with the stop-cock of an elevated vessel containing the remainder of the Alcohol, introduce that liquid into the retort, through the funnel-shaped tube, in a continuous stream; the quantity supplied being so regulated, that the temperature of the boiling liquid shall continue between the degrees mentioned. After all the Alcohol has been added, proceed with the distillation until the temperature rises to 286°, when the process should be discontinued. To the distilled liquid add the Potassa, previously dissolved in the Distilled Water, and shake them occasionally together. At the end of twenty-four hours, pour off the supernatant liquid, introduce it into a retort, and, with a gentle heat, distil into a well-cooled receiver three pints, or until the liquid attains the specific gravity 0·750. Lastly, keep the Ether in a well-stopped bottle." *U. S.*

"Take of Rectified Spirit *fifty fluidounces* [Imp. meas.]; Sulphuric Acid *ten fluidounces* [Imp. meas.]; Chloride of Calcium *ten ounces* [avoird.]; Slaked Lime *half an ounce* [avoird.]; Distilled Water *thirteen fluidounces* [Imp. meas.]. Mix the Sulphuric Acid with twelve fluidounces of the Spirit in a glass matrass capable of containing at least two pints [Imp meas.], and, not allowing the mixture to cool, connect the matrass by means of a bent glass tube with a Liebig's condenser, and distil with a heat sufficient to maintain the liquid in brisk ebullition. As soon as the ethereal fluid begins to pass over, supply fresh Spirit through a tube into the matrass in a continuous stream, and in such quantity as to equal the volume of the fluid which distils over. For this purpose use a tube furnished with a stop-cock to regulate the supply, connecting one end of the tube with a vessel containing the Spirit raised above the level of the matrass, and passing the other end through a cork fitted into the matrass. When the whole of the Spirit has been added, and forty-two fluidounces have distilled over, the process may be stopped. Dissolve the Chloride of Calcium in the Water, add the Lime, and agitate the mixture in a bottle with the impure ether. Leave the mixture at rest for ten minutes, pour off the light supernatant fluid, and distil it with a gentle heat until a glass bead of specific gravity 0·735 placed in the receiver begins to float. The ether and spirit retained by the chloride of calcium, and by the residue of each rectification, may be recovered by distillation and used in a subsequent operation." *Br.*

The preparation of ether embraces two stages; its generation, and its subsequent rectification to remove impurities. The formulas agree in obtaining it by the action of sulphuric acid on alcohol. In the United States process, which is adopted, with modifications, from that of the French Codex, one-third of the alcohol taken is mixed with the acid, and, while still hot from the reaction, distilled from a glass retort, by a heat quickly applied, into a refrigerated receiver. When the heat of the mixture has risen to between 266° and 280°, the remainder of the alcohol is allowed to enter the retort in a continuous stream, the supply being so regulated that the heat shall be maintained between the

degrees mentioned. By a complicated reaction which will be explained presently, the acid converts the alcohol into ether; and, were it not that the acid becomes more and more dilute as the process proceeds, it would be able to etherize an unlimited quantity of alcohol. Although the acid, before it becomes too dilute, is capable of determining the decomposition of a certain amount of alcohol, yet it is not expedient to add this amount at once; as a considerable portion of it would distil over undecomposed with the ether. The proper way of proceeding, therefore, is that indicated in the formula; namely, to commence the process with the use of part of the alcohol, and, when the decomposition is fully established, and a portion of ether has distilled, to add the remainder in a gradual manner, so as to replace that which, every moment of the progress of the distillation, is disappearing by its conversion into ether.

In the U. S. process of 1850, the point at which the distillation should cease was determined by the proportion of the ether distilled to that of the alcohol employed, or by the appearance of white vapours in the retort, which indicate the generation of other products beside the ether; but, in the present plan, arrangements having been made by which the temperature can be determined, the degree of heat has been adopted as a better criterion; as it is only when the temperature exceeds the point of 286° indicated, that the production of injurious impurities is to be apprehended. The modifications of the old process were made in conformity with suggestions by Dr. Squibb, contained in a paper published in the *Proceedings of the American Pharmaceutical Association* for the year 1858 (p. 390). The direction in the former process to reserve a small portion of acid, to be added gradually with the reserved alcohol, upon the supposition that the acid in the retort might be too much weakened to perform its part duly, has been found upon trial to result in no practical advantage. As the proper proportion between the acid and alcohol is that which requires for ebullition a temperature somewhat above 266°, or that at which the ether is formed, there is an obvious propriety in supplying the alcohol just so rapidly as may be sufficient to maintain this temperature in the liquid of the retort. If the alcohol be supplied so rapidly as to reduce the temperature below the point mentioned, alcohol will distil over in undue proportion; if too slowly supplied, the temperature will rise so high as to produce other reactions in the materials than that required for etherification, and various other products will result. The rising of the temperature to 286°, after all the alcohol has been added, is, therefore, an indication that the process should be suspended. Nevertheless, the caution to check the process when white vapours appear in the retort is not amiss, as affording an additional security that it shall not be carried too far. At the temperature of 320°, there would be generated sulphurous acid, heavy oil of wine, olefiant gas, and a large quantity of resino-carbonaceous matter, blackening and rendering thick the residuary liquid; all of them products arising from the decomposition of a portion of sulphuric acid, alcohol, and ether.

The *British* process is that of the late Edinburgh Pharmacopœia slightly modified. The principles are the same as those of the U. S. process; but the directions about temperature are wanting; and the regulation of the supply of alcohol, and the cessation of the operation, are made to depend on the less reliable method of determining the measure of liquid, in the first place in the retort, and in the second place in the receiver; as in the U. S. process of 1850.

In both processes, whatever care may be taken in conducting them, and to stop them in due time, yet the ether obtained is contaminated with sulphurous acid, heavy oil of wine, alcohol, and water; and hence its purification becomes necessary. This is conducted in different ways, according to the two Pharmacopœias. The U. S. Pharmacopœia directs for this purpose an aqueous solution of potassa, the British a saturated solution of chloride of calcium (muriate of lime), to which a portion of recently slaked lime has been added. In both cases, the crude ether is agitated with the purifying agent, and submitted to a new distillation at a gentle heat, called the *rectification*.

The purifying substances are potassa for sulphurous acid and water, and

water for alcohol in the U. S. formula; lime for acid, and a saturated solution of chloride of calcium for alcohol and water, in the British. The British substances for purifying are stated by Dr. Christison to be convenient, and to act perfectly and promptly. The chloride of calcium solution, after having been used, yields on distillation a further portion of ether of the officinal density; and, by concentrating it, filtering while hot, and separating the crystals of sulphite of lime which form on cooling, the chloride may be recovered for future operations.

The process for forming ether is conducted with most advantage on a large scale. At Apothecaries' Hall, where the operation is performed in this way, the apparatus employed is thus described by Mr. Brande. It "consists of a leaden still, heated by means of high pressure steam carried through it in a contorted leaden pipe. A tube enters the upper part of the still for the purpose of suffering alcohol gradually to run into the acid. The still-head is of pewter, and is connected, by about six feet of tin pipe, with a very capacious condensing apparatus, duly cooled by a current of water. The receivers are of pewter, with glass lids, and have a side tube to connect them with the delivering end of the condensing pipe." (*Manual of Chemistry*, edition of 1848.) For an account of the apparatus, used in the U. S. Naval Laboratory for obtaining ether by steam on a large scale, see an article by E. R. Squibb, M.D., U. S. Navy, contained in the *Am. Journ. of Pharm.* for Sept. 1856.

Properties of Officinal Ether. Notwithstanding the officinal directions for purifying ether, it is not absolutely pure as obtained by either of the formulas here given. Both contain a considerable proportion of alcohol, the U. S., according to Dr. Squibb, 25 per cent. of 88 per cent. alcohol, the British, according to the Pharmacopœia, 8 per cent. of alcohol by measure. In both, there is a little of the light oil of wine. They should, however, be free from various impurities, which are too often found in commercial ether, the result of careless operation, or the employment of imperfect processes. As both Pharmacopœias give special directions for the purification of ether, we shall postpone an account of the chemical and remedial properties of the medicine till the pure preparation is treated of. (See *Æther Fortior.*) In the mean time, it will be proper to indicate the means of determining the genuineness and purity of the proper officinal ethers. Commercial ether varies in sp. gr. from 0·733 to 0·765. The impurities found in it are excess of alcohol, water, sulphurous and other acids, heavy oil of wine, and various fixed substances.

The U. S. ether should have the sp. gr. 0·750, and, if heavier than this, must contain too much alcohol or water. When shaken with an equal bulk of water it should not lose more than from one-fifth to one-fourth of its volume. The statement that water takes up only one-tenth has been shown by Dr. Squibb to be erroneous. If it take up more than one-fourth, the ether must contain too much of alcohol or of water, or both. If the alcohol be in excess, it may be removed by agitating the liquid with twice its bulk of water, which unites with the alcohol, forming a heavier stratum, from which the ether may be poured off. The ether, however, takes up about one-tenth of water, which may be removed by agitation with fresh-burned lime, and subsequent distillation. An easy method for detecting and measuring any alcohol present in ether, was given by the Edinburgh College; namely, to agitate it, in a minim measure, with half its volume of a concentrated solution of chloride of calcium. This will remove the alcohol; and the reduction of the volume of the ether, when it rises to the surface, will indicate the amount. Heavy oil of wine may be discovered by the ether becoming milky upon being mixed with water. If the ether is pure, it wholly evaporates in the air, leaving no solid residue. All non-volatile impurities are thus detected. It should not redden litmus, showing the absence of acids. The point of ebullition is also an indication of the strength of the ether. A test tube, full of ether, should, when held in the closed hand, *begin to boil* on the addition of a piece of broken glass. (*Squibb*.) When evaporating from bibulous paper, it should offer only a slight degree of foreign odour, aromatic and free

from pungency, and should leave the paper, when dry, nearly or quite odourless. This test proves the absence of volatile impurities, except a slight and not inadmissible proportion of light oil of wine. (*Squibb.*)

The British ether should have the sp. gr. 0·735. Fifty measures, agitated with an equal volume of water, are reduced to 45 by an absorption of 10 per cent. It boils below 105°. It is, therefore, considerably stronger than the U. S. ether. In other respects, it should answer to the tests above given.

In the impure state in which ether is afforded by the U. S. Pharmacopœia, though it may answer for external application, and may even be given by the mouth, yet for purposes of inhalation, which is now the chief use of ether, it is scarcely fitted without further purification; and the same is true, though in a less degree, of the English preparation. Hence the propriety of the adoption, in the U. S. Pharmacopœia, of the *Stronger Ether.*

ÆTHER FORTIOR. *U. S.* Æther Purus. *Br. Stronger Ether. Pure Ether.*

"Take of Ether, Water, each, *three pints;* Chloride of Calcium, in fine powder, Lime, in fine powder, each, *a troyounce.* Shake the Ether and the Water thoroughly together, and, when the Water has subsided, separate the supernatant ether. Agitate this well with the Chloride of Calcium and the Lime in a well-stopped bottle, and allow the mixture to stand for twenty-four hours. Then decant the ether into a retort, and, having adapted thereto a Liebig's condenser, distil a pint and a half of Stronger Ether into a receiver refrigerated with ice-cold water. Lastly, keep the liquid in a well-stopped bottle. By continuing the distillation, a portion of weaker ether may be obtained." *U. S.*

"Take of Ether, Distilled Water, of each, *two pints* [Imperial measure]; Lime, recently burned, *a quarter of an ounce* [avoirdupois]; Chloride of Calcium, *four ounces* [avoird.]. Put the Ether with one pint [Imp. meas.] of the Water into a bottle, and shake them together; allow them to remain at rest for a few minutes, and, when the two liquids have separated, decant off the supernatant ether. Mix this with the remainder of the Water, and again, after separation, decant as before. Put now the washed ether, together with the Lime and Chloride of Calcium, into a retort to which a receiver is closely attached, let them stand for 24 hours, then distil with the aid of a gentle heat. Sp. gr. not exceeding 0·720." *Br.*

These formulas are essentially the same; the U. S. limiting the amount distilled by the measure, the British by the sp. gr. The ether is first shaken with the water, in order that the latter, by its superior affinity for alcohol, may take it from the former; and afterwards with the chloride of calcium and lime, to separate from the ether the water with which it has itself united in the first step of the process. Of course, the lime, for this purpose, must be in its freshly calcined state, so that it may have had no opportunity to absorb water from the air. The subsequent distillation is intended still further to strengthen the ether, the less volatile liquids being left in the retort. The lime answers the further purpose of neutralizing any sulphurous or other acid which the ether may have happened to contain. The weaker ether obtained at the end of the process may be kept for subsequent purification. It will be noticed that this separate process accomplishes more perfectly what is effected by the British formula for ether.

Even thus prepared, however, the ether, though sufficiently pure for all pharmaceutical or remedial purposes, is not absolutely pure, still containing a little

alcohol. To meet the intentions of the U. S. process, it must have the sp. gr. 0·728 (0·720, *Br.*), must lose not more than from one-tenth to one-eighth of its bulk by agitation with water, and must *boil actively* when a test-tube, half filled with it, is held enclosed in the hand, and a small fragment of glass is dropped into it. "Half a fluidounce of it, evaporated from a porcelain plate by causing it to flow to and fro over the surface, yields a faintly aromatic odour as the last portions pass off, and leaves the surface without taste or smell, but covered with a deposit of moisture." (*U. S.*) This last is Dr. Squibb's test to indicate the very minute proportion of light oil of wine that is still contained in the ether, and the absence of all other contaminating volatile impurities. The ether must not redden litmus; as the presence of acid matter would indicate that it had been badly prepared, or had been too long kept.

Properties. Ether is a colourless, very limpid liquid, of a strong and sweet odour, and hot pungent taste. When perfectly pure it has the sp. gr. 0·713, boils at 95°, and forms a vapour which has the density of 2·586. It is not frozen by a cold of 166° below zero. (*Faraday.*) It is a very volatile liquid, and, when of the sp. gr. 0·720, boils at about 98°. Its extreme volatility causes it to evaporate speedily in the open air, with the production of considerable cold. Its inflammability is very great, and the products of its combustion are water and carbonic acid. In consequence of this property the greatest care should be used not to bring it in the vicinity of flame, as, for example, a lighted candle. One of the great advantages of using steam as the source of heat is that it obviates, in a great measure, the danger of its accidental inflammation. When too long kept it undergoes decomposition, and is converted in part into acetic acid. It dissolves iodine and bromine freely, and sulphur and phosphorus sparingly. Its power to dissolve corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the organic vegetable alkalies. It does not dissolve potassa and soda, in which respect it differs from alcohol. Water dissolves a tenth of its volume of ether, and reciprocally ether takes up about the same proportion of water. When water dissolves more than a tenth of its volume, the ether is shown to contain an undue quantity of water or alcohol, or of both. Ether unites in all proportions with alcohol.

Composition and Theory of its Production. Ether consists of four eqs. of carbon, five of hydrogen, and one of oxygen, and its empirical formula is C_4H_5O. In volumes it consists of four volumes of carbon vapour, five volumes of hydrogen, and half a volume of oxygen, condensed into one volume. Its proximate constituents may be considered to be one eq. of ethylen (etherine) and one of water; or, in volumes, one volume of ethylen vapour and one volume of aqueous vapour, condensed into one volume. This view makes it a hydrate of ethylen ($C_4H_4 + HO$). The sp. gr. of its vapour, calculated on this constitution in volume, is 2·5817, which is very near 2·586, the number obtained by experiment. By most chemists, however, the constituents of the ethylen, together with the hydrogen of the alleged water, are supposed to form a peculiar radical, consisting of C_4H_5, to which the name of ethyl has been given. On this view, ether is an oxide of ethyl ($C_4H_5 + O$). The view is confirmed by Dr. E. Frankland, who has isolated ethyl by acting on iodide of ethyl with zinc. As described by him, *ethyl* is a colourless, inflammable gas, of the sp. gr. 2, incondensible at zero, but condensible, under a pressure of 2·25 atmospheres at 37·5°, into a colourless, mobile liquid. Ether was formerly called *sulphuric* ether, in allusion to the sulphuric acid employed in its preparation; but it contains no sulphuric acid, and an identical ether may be obtained by the action of other substances on alcohol. Hence the epithet sulphuric is improperly applied to it; and, accordingly, its name was changed from *Æther Sulphuricus* to *Æther* in the U. S. and Br. Pharmacopœias of 1850 and 1851. Those who consider ether as a compound of ethylen and water, call it hydric ether, or hydrate of ethylen; but its more probable constitution is expressed by the name, oxide of ethyl; and this view of its nature will be adopted in our subsequent remarks.

With a view to determine in what manner sulphuric acid acts upon alcohol in order to convert it into ether, it is necessary that a comparison should be instituted between the composition of the two latter fluids. Now alcohol is a hydrated oxide of ethyl, and ether is oxide of ethyl without water. It follows, therefore, that, to convert alcohol into ether, it is only necessary to abstract the water of the former. The agent in effecting this abstraction is evidently the sulphuric acid, which is known to have a strong affinity for water; but its action is not direct as originally supposed, but intermediate, as was first pointed out by the late Mr. Hennell. This chemist found that, when two eqs. of sulphuric acid and one of alcohol were merely mixed, the acid lost a portion of its saturating power, and a new acid was formed, to which he gave the name of *sulphovinic acid* (the *etherosulphuric acid* of Liebig). In view of its composition it may be called a bisulphate of alcohol, or, which is the same thing, a bisulphate of ether with one eq. of water, that is, a double sulphate of ether and water. When one eq. of this compound is heated it is decomposed; two eqs. of sulphuric acid with one eq. of water remain in the retort, while one eq. of ether distils over.

If the original proportion of acid and alcohol continued the same throughout the whole of the distillation, all the alcohol would be resolved into ether and water; but, during the progress of the process, the alcohol is constantly diminishing, and of course the relative excess of the acid becoming greater; and at last a point of time arrives when the excess of acid is so great that the generation of ether ceases. As these results depend upon the relative deficiency of the alcohol, while the acid remains unchanged in amount, it is easy to understand why it is advantageous to introduce alcohol gradually into the distilling vessel during the progress of the distillation; for, by this addition, the proper proportion of the alcohol to the acid is maintained. But the decomposing power of the acid has its limit; as it becomes at last too dilute to act upon the alcohol, notwithstanding a considerable portion of water, towards the close of the distillation, passes over with the ether.

The above theory of etherification was called in question, in 1851, by Prof. Graham, of London, who succeeded in producing ether without distillation, or the formation of sulphovinic acid, by using a larger proportion of alcohol than is ordinarily employed. The reaction was made to take place in sealed glass tubes heated for a short time to a temperature between 284° and 352°. The sulphuric acid appeared to act by mere contact with the alcohol, in determining the production of ether, without combining with anything. For a new theory of etherification see an article by M. E. Robiquet, in the *Journal de Pharmacie et de Chimie* for Sept. 1854.

Medical Properties and Uses. Ether is a powerful diffusible stimulant, possessed also of expectorant, antispasmodic, and narcotic properties. In low fevers attended with subsultus tendinum, it proves beneficial as a stimulant and antispasmodic. In these cases it is frequently conjoined with laudanum. It is useful also in nervous headache unattended with vascular fulness, and generally in nervous and painful diseases which are unaccompanied by inflammation. In nausea it is given as a cordial; and in cramp of the stomach and flatulent colic it sometimes yields prompt relief. Given alone, or mixed with oil of turpentine, it relieves the pain and spasm caused by the passage of biliary calculi. According to Mr. Brande, a small teaspoonful of ether, mixed with a glass of white wine, is often an effectual remedy in sea-sickness. In a case of chronic functional vomiting, Dr. Galante, of Arpino, found ether, given in capsules, of singular efficacy. Ether has recently received a new application from Dr. Lortet, of France. He uses it for the expulsion of the tapeworm, first administering a large dose of the ether, which renders the worm insensible, and thus disables it from holding its place in the bowels, and following this with a purgative medicine which expels the parasite. He gives 20 grammes (about 5 drachms) of ether at one dose, and two hours afterwards 30 grammes (between 7 and 8 drachms) of castor oil. He has found the remedy successful in all the cases, though not yet numerous, in which he has tried it. (*Ranking's Abstract*, xlv. 75; from *Gaz.*

Med. de Paris.) This dose of ether is very large; and the probability is that, by giving it at the same time as the purgative, and thoroughly mixed with it, the latter might convey it immediately into the intestines, where the worms are seated, and thus render a much smaller quantity sufficient. When externally applied ether may act either as a stimulant or refrigerant. Thus, it operates as a powerful rubefacient, and may even vesicate, when its evaporation is repressed; but, when this is allowed to take place freely, it is refrigerant in consequence of the cold which it produces. In the latter way it has been employed in strangulated hernia, dropped on the tumour and allowed to evaporate. Dr. J. Nunn, of Savannah, Ga., praises its effect as a local anæsthetic in recent burns, applied, *guttatim*, from a bottle, while the part is subjected to a stream of air. (*Charleston Med. Journ.*, Sept. 1855.) It sometimes produces immediate relief when dropped into the ear in earache. It may sometimes be used with great effect as a styptic in local hemorrhage. A case is related in which excessive bleeding from the socket of an extracted tooth, which had failed to yield to various other remedies, was checked at once by directing into the bleeding cavity the spray of ether by means of an atomizer (*Lancet*, May 16, 1868, p 641.) Another external employment of ether, introduced by Dr. B. W. Richardson, of London, is by the direction of its spray, by means of the atomizer or other similar instrument, upon any exposed portion of the body, to produce such a degree of cold in the part as to render it perfectly insensible, and thus enable the surgeon to operate upon it without causing pain. (See Dr. Wood's *Treatise on Therapeutics and Pharmacology*, 3d ed., ii. 15) For external use, the unrectified ether is sufficiently pure. The dose of ether is from fifty drops to a teaspoonful, to be repeated frequently when the full effect of the remedy is desired. When used habitually, the dose must be much increased to produce a given effect. It may be perfectly incorporated with water or any aqueous mixture, by first rubbing it up with spermaceti, employed in the proportion of two grains for each fluidrachm of the ether. (*Durand.*)

A *syrup of ether* is directed by the French Codex. MM. J. Regnault and Adrian, after a thorough investigation of the solubility of ether in solutions of sugar, offer the following formula. Take of sugar 440 parts, distilled water 490 parts, alcohol at 90° 50 parts, pure ether 20 parts. Put into a bottle, shake, and preserve. The whole of this might be given at a dose, if the parts taken are represented by grains. (*Journ. de Pharm.*, Janv. 1868.)

Ether is conveniently administered in capsules, each containing four or five minims of *pure* ether, according to the plan of M. Clertan, of Dijon. These capsules are made of sugared gum. (See *Capsules of Gelatin* in *Part* III.) *Capsules of ether*, also called *pearls of ether*, are inodorous, will keep for a year at least without loss, and furnish the means of introducing ether into the stomach, without irritating the mouth and throat. In a few seconds after they arrive in the stomach, they burst and diffuse their effects with singular rapidity. Analogous effects are produced when they are introduced into the rectum or vagina. Ether may be gelatinized by the process of M. Grimault. This consists in briskly shaking, in a stoppered bottle, four measures of ether, free from alcohol and acid, with one measure of white of egg. *Gelatinized ether* is an opaline trembling jelly, which may be spread with the greatest facility. It may be used as a local anæsthetic, applied to the seat of pain, spread on linen, and covered with a piece of cloth or of sheet caoutchouc. Gelatinized ether will not keep, but must be prepared at the time it is wanted.

Etherization. Ether may be exhibited by inhalation. Many years ago, its use in this way was proposed by Drs. Beddoes, Pearson, and Thornton, of England, in certain diseases of the lungs. As early as 1805, the late Dr. Warren, of Boston, employed ethereal inhalation to relieve the distress attending the last stage of pulmonary inflammation. About the year 1812, in Philadelphia, at a time when the nitrous oxide was the subject of popular lectures, the vapour of ether was frequently breathed from a bladder for experiment or diversion; and its effects in producing transient intoxication, analogous to that caused by the

nitrous oxide, were observed. It was not, however, until October, 1846, that attention was particularly drawn to ethereal inhalation as a remedy for pain. In that month, Dr. Warren, of Boston, was applied to by Dr. W. T. G. Morton, dentist of that city, to ascertain by trial whether an agent which he had successfully employed to render painless the extracting of teeth, would be equally successful in preventing the pain of surgical operations. This agent was the vapour of ether. Dr. Warren acceded to this request, and shortly afterwards, at the Massachusetts General Hospital, performed a severe operation, without pain to the patient, under the influence of ether, administered by Dr. Morton. A few days subsequently, Dr. C. T. Jackson, of Boston, in conversation with Dr. Warren, claimed to have first made known to Dr. Morton the use of ethereal vapour for the prevention of pain in dental operations.

From this beginning, the employment of ether by inhalation for the prevention and removal of pain, has spread throughout the civilized world. The effect produced, called *etherization*, probably takes place through the medium of the blood. It is sometimes partial, suspending sensibility, without abolishing consciousness; so that the patient, without feeling pain, is aware of everything that is passing around him. At other times, a perfect unconsciousness is produced.

Etherization is usefully resorted to in all severe operations, not merely as a remedy for pain, but as a means of preventing the shock which the system would otherwise suffer as a consequence of pain. Under full etherization, even the actual cautery may be extensively applied, without causing the least suffering. In many cases, the incidental power of ethereal vapour as a relaxing agent is usefully brought into play; as in the treatment of strictures of the urethra and œsophagus, strangulated hernia, retention of urine, dislocations, fractures, anchylosis, &c. In all these cases, the necessary surgical manipulations are very much interfered with by the muscular contractions excited by pain. This is particularly the case in dislocations, and in fractures attended with shortening of the limb. In partial anchylosis, etherization enables the surgeon in many cases to break up the adhesions, without pain to the patient, or resistance from the muscles. In lithotomy and lithotrity, the inordinate contraction of the muscular coat of the bladder is prevented or diminished. In short, in most cases in which the necessary surgical measures are likely to involve severe pain, or to encounter resistance, as in children, etherization may be usefully employed.

Etherization has been employed for the detection of feigned diseases, by suspending the operation of the will; in neuralgia, as a palliative; in tetanus, and in the spasms produced by an overdose of strychnia, as an antispasmodic; in asthma and chronic bronchitis, as an expectorant; and in dysmenorrhœa, as an anodyne and relaxing remedy. Dr. Warren found it useful in relieving the agonizing sufferings which often attend the latter complaint. In midwifery it is extensively employed as a safe agent; and, while it does not seem materially to interfere with the due contraction of the uterus, it promotes the relaxation and lubricating secretions of the soft parts. In vivisections, humanity calls for the use of ether vapour, or other anæsthetic agent.

Ethereal vapour is most conveniently inhaled through a soft sponge, hollowed out on one side to receive the projection of the nose, and saturated with ether of the purest quality. The sponge, thus prepared, is applied over the nostrils, through which the inhalation should be made in preference to the mouth. When the inhalation is thus conducted through a sponge, the ethereal vapour is copiously mixed with air, and there is no fear of inducing asphyxia. At first a short cough is generally produced, but this soon disappears; and, after the lapse of from two to five minutes, and the expenditure of about two fluidounces of ether, the quantity being very variable in different cases, the patient becomes insensible, and appears as if in a deep, almost apoplectic sleep. The usual signs of the full effect of the ether are the closure of the eyelids, muscular relaxation, and inability to answer questions. During the whole process of etherization, the fingers should be kept on the pulse; and, if it become feeble and very slow, the sponge should be removed until the circulation becomes more free. At first

there is redness, afterwards paleness of the face and neck, succeeded by cold perspirations. Should the etherization prove excessive, or convulsions supervene, an event which rarely happens, the ether must be immediately withdrawn, and cold water freely applied. This is the mode of proceeding in surgical operations; in midwifery cases, partial etherization is often sufficient. In a few cases persons become unmanageable under the influence of the ethereal vapour; and hence the propriety of a preliminary trial of its effects on a patient, before subjecting him to a surgical operation. In a few instances etherization has produced alarming remote effects. Dr. F. D. Lente has reported three cases of this kind. (*New York Journ. of Med.*, Nov. 1856.) Sometimes death has ensued; but the instances are extremely rare, in which a fatal result could be clearly traced to the direct influence of the ether. The Boston Society for Medical Improvement, having, by a committee, examined carefully into the subject of death from the inhalation of ether, declare, through their committee, that, though the reported cases of death which had been ascribed to this cause amounted to 41, yet in no one of the cases investigated by them was the fatal result fairly ascribable to etherization. (*Boston Med. and Surg. Journ.*, May 28, 1868, p. 272.)

CHLOROFORMUM PURIFICATUM. *U. S.* CHLOROFORMUM. *Br.*, *U. S.* 1850. *Purified Chloroform.*

"Take of Commercial Chloroform *one hundred and two troyounces:* Sulphuric Acid *seventeen troyounces;* Stronger Alcohol *six fluidrachms;* Carbonate of Potassa *two troyounces.* Add the Acid to the Chloroform, and shake them together occasionally during twenty-four hours. Separate the lighter liquid from the heavier, and mix it with the Stronger Alcohol. Then add the Carbonate of Potassa, previously heated to redness, and rubbed, while warm, into powder. Agitate the mixture thoroughly, and, by means of a water-bath, distil to dryness from a retort furnished with a condenser. Lastly, keep the distilled liquid in well-stopped bottles." *U. S.*

"Take of Chlorinated Lime *ten pounds* [avoirdupois]; Rectified Spirit *thirty fluidounces* [Imperial measure]; Slaked Lime *a sufficiency;* Water *three gallons* [Imp. meas.]; Sulphuric Acid *a sufficiency;* Chloride of Calcium, in small fragments, *two ounces* [avoird.]; Distilled Water *nine fluidounces* [Imp meas.]. Place the Water and the Spirit in a capacious still, and raise the mixture to the temperature of 100°. Add the Chlorinated Lime and five pounds [avoird.] of the Slaked Lime, mixing thoroughly. Connect the still with a condensing worm encompassed by cold water, and terminating in a narrow-necked receiver; and apply heat so as to cause distillation, taking care to withdraw the fire the moment the process is well established. When the distilled product measures fifty ounces, the receiver is to be withdrawn. Pour its contents into a gallon [Imp. meas.] bottle half filled with Water, mix well by shaking, and set at rest for a few minutes, when the mixture will separate into two strata of different densities. Let the lower stratum, which constitutes crude chloroform, be washed by agitating it in a bottle with three [fluid]ounces of the Distilled Water. Allow the Chloroform to subside, withdraw the water, and repeat the washing with the rest of the Distilled Water, in successive quantities of three [fluid]ounces at a time. Agitate the washed Chloroform for five minutes in a bottle with an equal volume of Sulphuric Acid, allow the mixture to settle, and transfer the upper stratum of liquid to a flask containing the Chloride of Calcium mixed with half an ounce of Slaked Lime, which should be perfectly dry. Mix well by agitation. After the lapse of an hour connect the flask with a Liebig's condenser, and distil over the pure Chloroform by means of a water-bath. Preserve the product in a cool place, in a bottle furnished with an accurately ground stopper. The lighter liquid which floats on the crude Chloroform after its agitation with

water, and the washings with Distilled Water, should be preserved, and employed in a subsequent operation." *Br.*

In the U. S. Pharmacopœia of 1850 a process was given for preparing chloroform; but as this is never made on a small scale by the apothecary, but purchased of the manufacturer, it was very properly transferred, at the late revision, to the Materia Medica Catalogue. But, as the chloroform of commerce is often impure, and, though fitted for external use, and for various pharmaceutical purposes, is, in this impure state, unfit for use as a respiratory anæsthetic agent, it was deemed advisable to introduce a formula by which its purification, if required, might be readily effected. This process is the first of those above given. The process of the British Pharmacopœia is for the preparation of the chloroform *ab initio*, with directions which secure its purity if complied with. In this process, the reaction by which the chloroform is produced takes place between the chlorinated lime and the alcohol; the slaked lime, which is added in accordance with the directions in the late Dublin Pharmacopœia, being intended probably to lessen the production of the chlorinated pyrogenous oil, the amount of which is greater, according to Soubeiran and Mialhe, in proportion to the relative excess of the chlorine to the lime employed. The use of this earth is stated by some chemists to give rise to Dutch liquid, $C_4H_4Cl_2$, and to increase the product at the expense of its purity. As first distilled, the chloroform is very impure, and is directed to be washed first with ordinary water, and afterwards with distilled water, which separate alcohol, chlorine, and probably other contaminating substances. In consequence of the density of the chloroform and its insolubility in water, it readily subsides, forming a distinct layer which may be easily separated. The crude product, after having been freed from alcohol by the washing with water, is purified from the chlorinated pyrogenous oil, which comes over with the chloroform, by agitation with an equal volume of sulphuric acid, which ought to be *pure* and *colourless*, and at least of the density 1·840. The oil is charred and destroyed by the acid, which becomes yellow or reddish-brown, and is partially changed into sulphurous acid. To remove the latter acid, as well as any water present, the chloroform, which floats on the surface of the acid, is removed and agitated well with chloride of calcium and slaked lime, and then again submitted to distillation. According to Gregory and Kemp, of Edinburgh, by whom the use of sulphuric acid for this purpose was proposed, chloroform is effectually purified from the pyrogenous oil by agitation with this acid if strong and pure. So long as a ring, darker than the rest of the acid, appears, after rest, at the line of contact between the acid and the chloroform, the agitation must be repeated; and the oil is known to be fully separated when the acid remains colourless. Deutoxide of manganese has been employed to separate the sulphurous acid; but, in this case, the chloroform is apt to become, after the lapse of a few weeks, of a delicate pink colour, which sometimes disappears and then returns. This coloration depends upon the presence of manganese, and forms an objection to the use of the deutoxide as a purifier.

In the U. S. process the method of purification is somewhat different. Instead of equal measures of the impure chloroform and sulphuric acid and an agitation for only 5 minutes, the commercial chloroform is shaken occasionally for 24 hours with but one-sixth of its weight of the acid. To remove any water and acid that may be present, instead of chloride of calcium and lime, a little stronger alcohol is mixed with the chloroform, and then carbonate of potassa previously heated to redness, and the mixture is distilled to dryness

It sometimes happens that the chloroform purified with sulphuric acid, though apparently pure at first, will not keep; but, after some time, becomes so loaded with chlorine and muriatic acid as to be altogether unfit for respiration. Dr. Christison ascertained that, if the sulphuric acid employed contains hyponitric acid, the chloroform changes in less than 24 hours. The idea has been entertained that it would be necessary to abandon sulphuric acid as a purifying agent; but experience has shown that, with certain precautions, it may be safely used; and its efficiency in getting rid of the empyreumatic impurity is so great

that it is still much employed for the purpose. The British Council endeavours to escape the difficulty by using a large quantity of the acid, and allowing but very brief contact; while, in the U. S. process, the same end is arrived at by employing a comparatively small quantity of the acid, with a much longer period for its operation. In any case, however, the acid should be strong and pure, and especially free from any of the nitrogen acids; and care should afterwards be taken to remove every particle of the sulphuric or sulphurous acid, as is done in the officinal processes, in one by lime, and in the other by carbonate of potassa. Dr. Squibb attributes the fact, that chloroform purified by concentrated sulphuric acid does not keep well, to the very purity attained. He believes that perfectly pure chloroform is prone to decomposition, and is rendered more stable by the addition of a small proportion of alcohol, so as to reduce its density to the officinal standard, 1·49. This he effects by adding alcohol in the proportion of ten drops to each fluidounce of good chloroform of maximum density. (See his paper on Chloroform in the New York *American Medical Monthly* for July, 1857.) This recommendation is carried into effect in the U. S. process, and explains the addition of alcohol before distillation. Dr. Gregory also attributes the tendency to decomposition to its purity, and to the action of sunlight; having found that those portions which he had purified with the greatest care were soonest decomposed under the influence of light.

As chloroform of great purity is often to be purchased in the market, it is not necessary for the apothecary to apply the officinal process of purification to every parcel that he may meet; but it is in the highest degree incumbent on him to sell none for inhalation which is not so pure as to stand the tests given in the Pharmacopœia, and if he can obtain none so pure, then to purify it himself. All pure specimens, moreover, should be kept distinct, and labelled with the officinal title of Purified Chloroform, for the sake of distinction.

Chloroform may be made by the action of chlorinated lime on pyroxylic spirit (wood spirit); but when thus prepared it is largely contaminated with a chlorinated pyrogenous oil, analogous to that already mentioned as being found in small proportion in chloroform prepared from alcohol. Chloroform, thus prepared, called *methylic chloroform*, is purified with too much difficulty to be advantageously substituted for that made with alcohol, called by Soubeiran *normal chloroform*. In Great Britain chloroform is now obtained by the use of methylated spirit; and the preparation, when properly purified, is stated to answer every purpose to which it is applied equally well with that obtained by the use of alcohol. (See *Methylic Alcohol* in *Part* III.)

Messrs. Duncan and Flockhart, druggists of Edinburgh, manufactured chloroform on a large scale, in a peculiar apparatus, using the proportions of 20 parts of chlorinated lime, about 3 75 parts of rectified spirit, and 60 parts of water. They employed two large wooden barrels as a still, and a third as a receiver, and into the former threw steam, which furnished both sufficient heat and water for the process. Sixty pounds of chlorinated lime were used by them at each distillation; and they were able to manufacture three hundred ounces of chloroform a day. The heavy layer of the distillate, constituting the impure chloroform, was purified by them by mixing it with half its measure of strong sulphuric acid, gradually added, and distilling the mixture, when cool, in a leaden retort, from as much carbonate of baryta by weight as of acid used by measure. The product was finally distilled from quicklime, after having stood over the earth, and been repeatedly shaken with it, for a day or two. Though sulphuric acid is used in this long-tried process, it may be presumed that the chloroform made by it is not liable to undergo the change which takes place in that prepared by Gregory's process. It will be observed, however, that the product, after the action of the sulphuric acid, is successively distilled from baryta and lime.*

Pettenkofer inferred, from numerous experiments on the manufacture of

* In the *Am. Journ. of Pharm.* for Jan. 1862 (p. 25) is an account by Prof. Procter of the method employed by Messrs. Rogers and Crew, of Philadelphia, wholesale manufacturers of chloroform, and the apparatus used by them.

chloroform, that very different quantities are obtained, on different occasions, from the same amount of materials, and the same process. The yield is less, the longer the mixture is allowed to stand before distillation, and is greater when the heat of the mixture is between 135° and 167° F. than at either a lower or higher temperature. When the latter degree is exceeded, the chloroform contains more chlorine. (*Buchner's Neues Repert.*, x. 103.)

Discovery and History. Chloroform was discovered by Mr. Samuel Guthrie, of Sackett's Harbor, N. Y., in 1831, and about the same time by Soubeiran in France, and Liebig in Germany. Guthrie obtained it by distilling a gallon from a mixture of three pounds of chlorinated lime and two gallons of alcohol of the sp. gr. 0 844, and rectifying the product by redistillation, first from a great excess of chlorinated lime, and afterwards from carbonate of potassa. (*Silliman's Journal*, vol. xxi., Jan. 1832, p. 64.) In a subsequent letter to Professor Silliman, dated Feb. 15th, 1832, Mr. Guthrie states that the substance which he had obtained, "distilled off sulphuric acid, has the specific gravity of 1·486, or a little greater, and may then be regarded as free from alcohol; and if a little sulphuric acid which sometimes contaminates it be removed by washing it with a strong solution of carbonate of potassa, it may then be regarded as *absolutely pure*." (*Ibid.*, vol. xxii., July, 1832, p. 105.) It is thus evident that Mr. Guthrie obtained, in a pure state, the substance now called chloroform; but he erroneously supposed his product to be the well-known oily liquid of the Dutch chemists, which it greatly resembles, and for the preparation of which he believed he had fallen on a cheap and easy process. Under this impression, he called the substance, in his communications, *chloric ether*, one of the names by which the *Dutch liquid*, or *bichloride of ethylen*, is designated. He was induced to make the preparation from noticing, in Professor Silliman's Elements of Chemistry, a reference to the Dutch liquid as a grateful diffusible stimulant, when properly diluted with alcohol and water. In relation to the anticipated importance of chloroform, Mr. Daniel B. Smith, of this city, held the following language in July, 1832. "The action of this ether on the living system is interesting, and may hereafter render it an object of importance in commerce. Its flavour is delicious, and its intoxicating qualities equal to or surpassing those of alcohol. It is a strong diffusible stimulus, similar to the hydrated ether, but more grateful to the taste." (*Journ. of the Philad. Col. of Pharm.*, iv. 118.)

Properties. Chloroform is a limpid, colourless, volatile, neuter liquid, having a bland ethereal odour, and hot, aromatic, saccharine taste. It neither reddens nor bleaches litmus paper. It is but slightly soluble in water; one hundred parts of that liquid taking up but one part of chloroform. Its sp. gr. is from 1·49 to 1·494 (*U. S.*), 1·49 (*Br.*); but when of this density it contains a small proportion of alcohol. Gregory has obtained it of the density 1·5 at 60°. It boils at 140°. It is not inflammable, but renders the flame of an alcohol lamp yellow and fuliginous. It burns, however, with a smoky flame, when mixed with an equal volume of alcohol. When pure, it has no action on potassium, except to cover the surface of the metal with small bubbles of gas. Chloroform is a powerful antiseptic. It does not, like creasote, coagulate albumen. It is scarcely acted on by sulphuric acid in the cold, but dissolves readily in alcohol and ether. The alcoholic solution, when moderately diluted with water, forms an aromatic, saccharine liquid of a very grateful taste. A strong alcoholic solution is decomposed by abundance of water, the chloroform separating and subsiding, and the alcohol uniting with the water. It is liable to decomposition by sunlight, or even diffused daylight; and hence the propriety of keeping it in bottles, covered with dark paper, in a rather dark place. Chloroform has extensive solvent powers, being capable of dissolving caoutchouc, gutta-percha, mastic, elemi, tolu, benzoin, and copal. Amber, sandarac, lac, and wax are only partially soluble. It also dissolves iodine, bromine, the organic alkalies, the fixed and volatile oils, most resins, and fats. It dissolves sulphur and phosphorus sparingly. It possesses the power of dissolving a large quantity of camphor, and furnishes the means of administering that medicine in an elegant form. As a

general solvent, it has the advantage over ether of not being inflammable; the inflammability of the latter being the cause of frequent accidents. For an extensive list of substances, soluble, insoluble, and partly soluble in chloroform, see a paper by M. Lepage, of Gisors, France, copied into the *Am. Journ. of Pharm.* for April, 1852, p. 147.*

Composition. Chloroform is composed of three eqs. of chlorine and one of formyl, and is, therefore, the terchloride of formyl. As formyl is a bicarburet of hydrogen, the formula of chloroform is C_2HCl_3. Its composition was first accurately determined by Dumas in 1835, by whom it was called chloroform from its relation to formic acid (C_2HO_3), being formic acid with its three eqs. of oxygen replaced by three of chlorine. When first obtained by Liebig, he supposed it to consist exclusively of chlorine and carbon; and hence the origin of the erroneous name, sometimes applied to it, of *perchloride of carbon.*

The rationale of the formation of chloroform has not been well made out. If alcohol be considered a bihydrate of ethylen, C_4H_4+2HO, it may be presumed to be generated by the removal from the ethylen of two eqs. of carbon, and the substitution of three eqs. of chlorine for three of hydrogen. Thus $C_4H_4-C_2H_3+Cl_3=C_2HCl_3$.

Impurities and Tests. Chloroform is liable to contain alcohol and ether, both of which lower its specific gravity. If it have a less density than 1·38, it will float instead of sinking in a mixture of equal weights of concentrated sulphuric acid and water, after it has cooled. M. Mialhe has proposed the following test for the presence of alcohol. Drop into distilled water a small quantity of the chloroform. If pure, it will remain transparent at the bottom of the glass; but, if it contain even a small proportion of alcohol, the globules will acquire a milky appearance. Soubeiran's method was to agitate almond oil and chloroform together in a tube. If the chloroform is pure it remains clear, if it contains as much as 5 or 6 per cent. of alcohol, it becomes milky. (*Journ. de Pharm.*, Août, 1860, p. 95.) Prof. Procter detects alcohol by adding the suspected chloroform to an oxidizing mixture of bichromate of potassa and sulphuric acid. If alcohol be present, the deep-orange colour of the chromic mixture will gradually become green; if absent, no change of colour will take place. (*Am. Journ. of Pharm.*, May, 1856, p. 213.) Alcohol is detected also by potassium or sodium, which colours the chloroform containing this impurity, and gives rise to sharp acid fumes. But the most sensitive test is probably a compound newly discovered by M. Roussin, the binitrosulphuret of iron, a little of which agitated with chloroform and then allowed to stand, if there be the least proportion of alcohol, will produce a brown tint, deeper in proportion to the quantity, while the chloroform if pure will remain unchanged. To obtain this compound it is sufficient to mix nitrate of potassa and hydrosulphate of ammonia in solution, and to add a solution of protosulphate of iron, stirring constantly, until the liquid has but a slightly alkaline reaction, then evaporating to dryness, treating the residue with etherized alcohol on a filter, and evaporating the liquor so that it may crystallize. (*Journ. de Pharm.*, Sept. 1858, p. 208.) The most injurious impurities are the chlorinated pyrogenous oils, already alluded to. These are different as obtained from methylic or normal chloroform. The oil, obtained by Soubeiran and Mialhe from methylic chloroform, is an oleaginous, yellow liquid, lighter than water, and of a peculiar nauseous empyreumatic odour, perceptible in the methylic

* The following table of the solubility of the several alkaloids and their salts in chloroform, prepared with great care by A. Schlimpert, may be of some practical use. At 64° F. 100 parts of chloroform dissolve

Cinchonia	2·50	Nitrate of strychnia	6·60	Santonin, impure	33·30

(*Am. Journ. of Pharm.*, March, 1860. p. 160; from *Archiv. der Pharm.*, Nov. 1859, p. 151.)—*Note to the twelfth edition.*

chloroform itself. In commercial chloroform it is sometimes present to the amount of 6 per cent. It is easily set on fire, and burns with a smoky flame, chlorine being among the products of its combustion. The oil procured from normal chloroform, which contains it in the amount of about one-fifth of 1 per cent. only, is essentially different from the methylic chloroform oil. It is heavier than water, and has an acrid, penetrating odour, unlike that of the other oil. When the vapour of these oils is inspired or even smelt, it causes, according to Dr. Gregory, distressing sickness and headache. These pyrogenous oils are detected and removed by *pure* and *strong* sulphuric acid. Chloroform, when pure, upon being mixed with an equal volume of this acid, does not colour it; but, when contaminated with these oils, gives the acid a colour, varying from yellow to reddish-brown, according to the amount of impurity. Alcohol also is detected and removed by sulphuric acid. In applying this test, several fluidounces of chloroform should be used; as a slight change of colour cannot be easily seen in a test tube. A still more delicate test of the oily impurities, according to Dr. Gregory, is the smell which they leave. If chloroform, thus contaminated, be poured upon the hand, it quickly evaporates, leaving the oily impurities, recognisable by their offensive odour, now no longer covered by that of the chloroform. The pure substance, rubbed on the skin, quickly evaporates, and scarcely leaves any smell. Chloroform sometimes contains Dutch liquid, which may be discovered by adding an alcoholic solution of potassa; when the mixture, if this impurity be present, will heat, and give off a permanent gas, which is chloride of acetyl, C_4H_3Cl. (*Geuther.*)*

Certain conclusions of Prof. John M. Maisch upon the subject of chloroform, drawn from a series of practical and experimental observations, are worthy of notice. Chloroform may be made of the sp. gr. 1·5, or perhaps somewhat heavier, and this is its density when pure; but it will not keep so well as when of the officinal strength from 1·490 to 1·494. When pure, or even of the sp. gr. of about 1·49, it is quickly decomposed in direct sunlight, and more slowly in diffused daylight; and the presence of water, however small in quantity, favours the decomposition. The products of its decomposition are muriatic acid and phosgene gas. If, however, it be perfectly excluded from the light, it will keep indefinitely; Wiggers having preserved some unaltered for fifteen years. According to Schacht, moreover, pure chloroform will resist even sunlight, if in a perfect vacuum. To prevent the decomposition of chloroform the most effectual means is the addition of alcohol. If reduced by this to the sp. gr. 1·480 or 1·484, it will keep well in diffused daylight, and, for a time at least, even in the sun's rays, if perfectly free from moisture. At the sp. gr. 1·475 or lower, it remains unaffected whether in diffused light or in the sun, and whether the bottles be damp or dry. The measures, therefore, to secure chloroform from decomposition are two, either of which will answer; first, to keep it perfectly secluded from light, from the moment of rectification; or, secondly, to reduce the sp. gr. to 1·475 by alcohol, as suggested by Dr. Squibb. Sulphuric acid will not decompose chloroform in the dark; in the light it evolves muriatic acid. One of the best criteria of its purity is a constant boiling point. When of the sp. gr. 1·496, it boils at 152·6° F. A slight acid reaction in chloroform is not easily detected, as litmus is quite insoluble in that fluid. It is best observed by allowing a few drops of chloroform to evaporate spontaneously with one drop of an aqueous solution of litmus duly neutralized. The colour will be changed to reddish. After becoming acid, chloroform may be readily regenerated, by agitating it with solution of carbonate of soda, and distilling from a little unslaked lime. From what has been said above, chloroform to be kept for use should have the sp. gr. 1·475, and if denser than this, should be brought to it by the addition of alcohol. It is best kept in cork-stoppered bottles. As the cork is not acted on by chloroform, if it become yellow and softened, it will indicate the presence of an acid, and thus act as a test. (*Am. Journ. of Pharm.*, July, 1868, p. 289.)

* In relation to chloroform, see the paper of Soubeiran and Mialhe, *Journ. de Pharm.*, July, 1849, copied into the *Am. Journ. of Pharm.*, xxi. 313; also the paper of Dr. Gregory, *Chem. Gaz.*, May 15, 1850.

Boettger states that chloroform altered by the sun's rays, containing muriatic acid and having a chlorinous odour, may be restored and made fit for inhalation by agitation with a few fragments of caustic soda, and that the fluid may be kept exposed to light, if protected in the same way. (*Ibid.*, Sept. 1866, p. 473; from *Journ. de Pharm.*, Avril, 1864.)

Officinal Tests. The U. S. Pharmacopœia directs that purified chloroform should have a sp. gr. not less than 1·490 nor exceeding 1·494; should boil at 140°; when dropped into water should sink in the form of transparent globules without milkiness; should produce no warmth, sensible to the hand at the moment when mixed, in a bottle closed by a glass stopper, with an equal measure of officinal sulphuric acid, and that, when the liquids have separated on standing, and have been allowed to remain in contact for 24 hours, no colour should be imparted to either, or but a faint yellowish tinge to the acid, forming the lower layer. The Pharmacopœia directs, moreover, that when 3 or 4 fluidrachms are evaporated from a porcelain plate, by causing them to flow to and fro over the surface, the last portions should have a slightly aromatic odour, without pungency or empyreuma, while the plate is covered with a film of moisture, without odour or taste. These tests imply the presence of but a minute proportion of alcohol, and the total absence of chlorine and those volatile and empyreumatic substances which constitute the most injurious impurities of chloroform. A heat that would be felt through the bottle, on the admixture of sulphuric acid with chloroform, would evince the presence of too much alcohol or water. The want of discoloration from the contact of the two liquids shows the absence of empyreumatic oily matter; but a very slight discoloration might proceed from the alcohol present, and would not, therefore, be a material objection. A colour bordering on that of madeira wine would imply an objectionable amount of impurities. The volatile impurities are less volatile than chloroform, and would consequently be the last to escape on the evaporation of the liquid. Chloroform, therefore, leaves a foreign odour behind it when allowed to evaporate from the hand, and especially when from a porcelain plate, in the amount and manner indicated; and if it stand this test well, it may be considered as free from any noxious volatile impurity. The slight foreign aroma without pungency, which is given out under these circumstances, is of no injurious significance.*

Medical Properties, &c. When taken *internally*, chloroform acts as a sedative narcotic, probably operating through the nervous system, independently of vascular action or congestion. It has been detected by Ragsky in the blood, and by Dr. Snow, of London, in different parts of the body after death.† In 1848 Dr. H. Hartshorne tried its physiological effects in the dose of seventy-five drops on himself, and found it to produce drowsiness and a general diminution of sensorial power, without exhilaration, or acceleration of the pulse. Since then he has used it internally in a number of cases, and finds it a safe anodyne and soporific, altogether free from the dangerous effects which sometimes follow the inhalation of its vapour. In the dose of a fluidrachm, its soporific effect is about equal to that of thirty-five drops of laudanum. Dr. Hartshorne has given it in doses of from fifty to seventy-five drops every half hour for several hours together. The vehicle used by him is orgeat syrup, in the proportion of two fluidounces to each fluidrachm of the chloroform. When mixed with mucilage of gum arabic, the mixture requires agitation immediately before swallowing each dose.‡

Chloroform, as prepared by Mr. Guthrie, was used internally as early as 1832

* Much is due to Dr. Squibb for the precision given to the tests for chloroform; and the reader may profitably consult his remarks on the subject in a paper in the *Proceedings of the Pharmaceutical Association*, A. D. 1858, p. 402.

† In relation to the detection of chloroform in the body after death, see the paper of M. Duroy, of Paris, in the *Journ. de Pharm.*, Avril, 1851.

‡ The Society of Pharmacy, of Paris, has given its sanction to the following formula; the French weights being turned into the nearest English weights and measures. Take of chloroform ʒss to ʒj; sugar ʒiij; gum arabic ʒj to ʒij; water fʒiijss. Rub the chloroform with the sugar in a mortar, then add the gum, and, lastly, by degrees, the water In this recipe alcohol, which is often inadmissible, is avoided.

by Professor Ives and Dr. Nathan B. Ives, of New Haven, in asthma, spasmodic cough, scarlet fever, and atonic quinsy, with favourable results. (*Silliman's Journ*, xxi. 406, 407.) It was employed by Dr. Formby, of Liverpool, in hysteria, in 1838; by Mr. Tuson, of London, in cancer and neuralgic affections, in 1843; and by M. Guillot, of Paris, in asthma, in 1844. Dr. L. Dalton, of Logan, Ohio, has found it to possess antiperiodic powers, and employed it successfully in intermittent diseases. Dr. Delioux, of Rochefort, has also proposed it as a remedy in intermittents, given, during the apyrexia, in cases in which the bark and quinia fail to effect a cure. Dr. Aran has employed it for four years with success in lead colic, administered by the mouth and rectum, and applied to the abdomen In these cases it probably acts by relaxing the intestinal spasm. It has been found very effectual in hiccough. One of the authors of this work has frequently used it with advantage for the relief of neuralgic and other painful affections, in the dose of from forty to eighty drops, suspended in water by means of gum arabic or yelk of egg. This dose may be repeated, if necessary, at intervals of one or two hours, until some effect on the system is produced. Chloroform has been used internally, with benefit, by Dr. Osburn, of Dublin, in hypochondriasis, and by Dr. Gordon, physician to the Hardwicke Fever Hospital, to allay nervous irritation and procure sleep. A disadvantage connected with the internal use of chloroform is its liability to sicken the stomach, an effect which may sometimes arise from the presence of pyrogenous oil. An incidental advantage is said to be, that it entirely covers the bitterness of other medicines. M. Dauzats, of Cordova, Spain, has used chloroform, with highly favourable results, in the destruction of the larvæ of insects, which sometimes make great ravages in the nostrils, pharynx, &c. Simple inhalation of chloroform is sometimes sufficient to destroy the insects in large numbers; but it is always prudent to employ injections composed of equal parts of chloroform and water, which may be considered infallible. If chloroform is not at hand, ether may be substituted. (*Ann. de Thérap.*, 1867, p. 43.)

Externally, chloroform has been used by Mr. Tuson in cancer, senile gangrene, and sloughing ulcers, and, as an injection and gargle, in discharges from the uterus and foul ulcers of the throat, with the effect of relieving pain, destroying fetor, and promoting the separation of diseased parts. It has also been employed externally, with benefit, in a painful wound of the forearm implicating the radial nerve; by Dr. Legroux in a painful affection of one of the lower extremities, consequent to a cancerous tumour of the pelvis; by Mr. Higginson in labour, applied to the perineum when painfully stretched, and in dysmenorrhœa, brought in contact with the os uteri by means of a sponge; by Dr. Watson in swelled testicle and acute spinal tenderness; by Dr. Hays and Dr. Bond in neuralgia; by the late Dr. I. Parrish in the supra-orbitar pain of rheumatic ophthalmia, and in syphilitic ulceration at the root of the nail; by M. Devergie in papulous eruptions, made into an ointment in the proportion of a fluidrachm to ten drachms of lard; by Prof. Back in the itch; and by M. Chapell in fissure of the anus. It has also been used with success by Dr. Venat, of Bordeaux, in the form of injection, in the commencement of acute gonorrhœa, as an abortive treatment. Dr. Rauch, of Iowa, has employed chloroform topically with decided benefit in neuralgia, colic, and other painful affections. For some purposes he found it useful to incorporate it with olive oil and solution of ammonia, which formed a mixture having effects less transient than those of the uncombined substance. Incorporated in equal measure with the white of eggs, and applied on lint to the gums, it is said to afford great relief in toothache. As a wash, injection, and gargle, Mr. Tuson prepared chloroform diluted with water, in the proportion of one or two drachms to the pint; but, for application to the sound skin, it is generally used undiluted, by means of soft linen, covered with oiled silk to prevent evaporation. Employed in this state it should be pure; as, according to Mialhe, when mixed with absolute alcohol, it acquires caustic properties.

M. Fournié has found that the vapour from a mixture of equal measures of glacial acetic acid and chloroform is even more effectual, as a local anæsthetic,

than that of pure chloroform; producing complete insensibility of the skin in five minutes, if applied from a bottle heated simply by the hand. (*Pharm. Journ.*, Jan. 1862, p 385; from *Comptes Rendus.*)

Chloroform may be gelatinized by agitating it with an equal weight of white of egg in the cold. In three hours it takes the gelatinous form. A stronger preparation may be made by shaking together, in a bottle, four parts of chloroform and one of white of egg, and placing the mixture in water at 140°. In four minutes the gelatinization is completed. *Gelatinized chloroform* may be applied to the skin, spread on linen, or by frictions.

Chloroform, in vapour, may be used as a topical application to the rectum M. Ehrenreich employed it with success in tenesmus. A drachm may be vaporized by the heat of warm water from a bottle, fitted with a flexible tube, inserted into the bowel. It may be applied to the skin in the form of a vapour douche, according to the method of Dr. Hardy, of Dublin. (See *Ranking's Abstract*, no. 19, p. 287.) Prof. Langenbeck, of Berlin, prefers chloroform to tincture of iodine, as an injection for the radical cure of hydrocele.

A third method of using chloroform is by *inhalation.* The first case we have met with in which it was thus employed is related by Professor Ives, of New Haven, under date of the 2d of Jan. 1832. The case was one of pulmonic disease, attended with general debility and difficult respiration, and was effectually relieved. (*Silliman's Journ.*, vol. xxi., Jan. 1832, p. 406.) In March, 1847, the action of the pure substance by inhalation was tried on the lower animals, by M. Flourens, and its effects on the spinal marrow described. In November of the same year, Dr. Simpson, of Edinburgh, after experimenting with a number of anæsthetic agents in order to discover a substitute for ether, tried chloroform at the suggestion of Mr. Waldie, and, having found its effects favourable, brought it forward as a new remedy for pain, by inhalation in surgery and midwifery. The advantages which he conceived it to possess over ether were the smallness of the dose, its more prompt action, more agreeable effects, less tenacious odour, greater cheapness, and greater facility of exhibition.

The usual effects produced by a full dose of chloroform, administered by inhalation, are the rapid production of coma, relaxation of the muscles, slow and often stertorous breathing, upturning of the eyes, and total insensibility to agents which ordinarily produce acute pain. The effect on the heart's action is variable. Sometimes frothing of the mouth takes place, and, more rarely, convulsive twitches of the face and limbs. The insensibility is generally produced in one or two minutes, and usually continues for five or ten minutes; but the effect may be kept up for many hours, provided the inhalation be cautiously renewed from time to time. The immediate effects of the agent are followed by a drowsy state, sometimes by quiet sleep. As a general rule, no recollection is retained of anything that occurred during the state of insensibility. Experience has shown that the effects, here described as those of a full dose of chloroform by inhalation, cannot be induced without danger to life. Hence all prudent surgeons will be content with an impression short of the abolition of all consciousness. It is generally admitted that, at a certain stage of anæsthesia, there is insensibility to pain, while consciousness to a certain extent remains; and it is this condition that the surgeon should aim to produce. According to Mr. Skey, chloroform had been administered up to 1854, in 9000 cases in St. Bartholomew's Hospital, without a single accident, a fact which must be taken as proof of its careful employment in that institution. The delicate operation of extracting the cataract has been facilitated by its use, in the hands of Mr. Bowman, of London; and, in general, the performance of operations on the eyeball is greatly assisted by the insensibility produced, especially in children. In partial anchylosis, in which the surgeon proposes to break up the adhesions by force, chloroform, like ether, takes off the muscular resistance, and renders the manipulations painless. It is asserted to be an advantage of chloroform in surgical operations, that less blood is lost. If this assertion should prove to be true, there will be greater necessity of delaying the dressings until reaction shall have

taken place. The question whether the use of chloroform in the major operations of surgery is favourable or otherwise to recovery, has been examined by an appeal to statistics. Dr. Simpson, of Edinburgh, thinks the percentage of recoveries has been increased by its use; while Dr. Arnott, basing his opinions on the results of operations in the London hospitals, holds the contrary opinion.

The advantages and disadvantages of chloroform, when compared with ether as an anæsthetic in operative surgery, have not been satisfactorily determined; but on one point the evidence appears to be conclusive, namely, that it is far more dangerous to life than ether. According to Dr. Snow, of London, the vapour in the air breathed by the patient should not exceed 6 per cent. Dr. Gilman, of New York, thinks that chloroform has a more sudden and powerful effect than under ordinary circumstances, when inhaled immediately after bleeding; a fact which he explains by the increased power of absorption produced by the loss of blood. (*N. Y. Med. Times*, Oct. 1852.)

As chloroform is powerfully sedative, and ether powerfully stimulant, it was very naturally supposed that, by combining them, the depressing effects of the former might be counteracted by the latter; but experience has not altogether confirmed the suggestion of theory in this case; as fatal effects have followed the joint administration of the two anæsthetics. This result may be in part explained by the more rapid volatilization of the chloroform, which may cause it to reach the surface of absorption with comparatively little admixture of the ethereal vapour, as suggested by Mr. Robert Ellis. (*Med. Times and Gaz.*, March 9, 1867.)

Sometimes chloroform produces unpleasant remote effects; such as abolition of smell, perversion of taste, and loss of tonicity in the bladder and rectum. Two cases, illustrative of these effects, in which chloroform was inhaled in excess, are related by Dr. Happoldt in the *Charleston Med. Journ.* for Jan. 1856.

In midwifery, chloroform has been extensively employed to relieve pain and facilitate labour, since it was first recommended by Dr. Simpson. Its effects are similar to those of ether; and each agent has its exclusive advocates among those practitioners of midwifery who are willing to use anæsthetics. According to Dr. Atthill, of Dublin, the use of chloroform produces a tendency to post-partum hemorrhage. Dr. Robert Lee, of London, has cited seventeen cases, in which it was supposed to produce various pernicious effects in labour. (*Lancet*, Dec. 24, 1853.) Notwithstanding exceptional cases of injury, it is every year growing in favour as an anæsthetic in parturition. The profession is unanimous as to its great utility in instrumental labours.

The dose of chloroform for inhalation is a fluidrachm, equivalent to 220 drops or more, to be repeated in two minutes, if the desired effect should fail to be produced. The most convenient inhaler is a handkerchief, loosely twisted into the form of a bird's nest, which, after having been imbued with the chloroform, is held to the mouth and nose. The use of this simple inhaler ensures a due admixture of atmospheric air with the vapour of the chloroform. The moment insensibility is produced, which should be brought on *gradually*, the inhalation should be suspended; and, if consciousness return too soon, it should be cautiously renewed. In all cases an experienced assistant should attend to the administration of the chloroform and to nothing else, watching the state of the respiration and pulse. The moment there is the least snoring or failure of the pulse, the vapour should be withdrawn. Chloroform should not be administered to persons subject to epilepsy, affected with organic disease of the heart, or predisposed to syncope.*

Chloroform, as ordinarily prepared, is apt to produce, when inhaled, headache, nausea, and even vomiting. Perfectly pure chloroform, according to Soubeiran and Mialhe, does not produce these disagreeable effects, which are plausibly attributed to the presence of the pyrogenous oils. Dr. Simpson, however, finds

* For rules laid down by M. Baudens for the administration of chloroform, see the *Am. Journ. of Med. Sci.* for Jan. 1854, p. 208; and for those given by M. Robert, surgeon to the Hospital Beaujon, see *Ranking's Abstract*, no. 19, p. 116.

that the purest chloroform that he uses not unfrequently causes vomiting; but Dr. Gregory attributes this effect, when following the use of the pure substance, to its administration after a full meal, which should always be avoided.

Chloroform having proved to be a relaxing agent and remedy for pain, when used by inhalation in surgery and midwifery, it was natural that its effects should be tried in the same way in spasmodic and painful diseases. Accordingly, it has been inhaled in hiccough, chorea, hooping-cough, hysteria, the paroxysm of asthma, angina pectoris, nephritic colic, tetanus, poisoning from strychnia, hydrophobia, and the paroxysm of tic douloureux, and generally with decided advantage. In Germany it has been praised in bronchitis and pneumonia as an expectorant and calming remedy. It has been employed also with success for the reduction of strangulated hernia. Mr. R. J. Mackenzie, of Edinburgh, bears testimony to its good effects, used by inhalation, in spasmodic stricture of the urethra, attended with retention of urine. Sometimes the urine is caused to flow at once; and, when this is not the case, the passage of the catheter is facilitated. Dr. Cain, of Charleston, found it very useful in spasmodic obstruction of the bowels, promptly relieving pain, and favouring the action of enemata. As a soporific it has been given beneficially in delirium tremens, and in the noisy forms of chronic insanity.

Much has been said in relation to the dangers attendant upon the inhalation of chloroform, and, certainly, many more deaths have been reported from its use than from that of ether. The late Dr. Warren, of Boston, published, in 1849, the details of ten cases, in which death was caused by chloroform, all occurring in little more than a year, and many other fatal cases have since occurred; and he declared that, if he were compelled to substitute chloroform for ether in inhalation, he would do it with much anxiety. Chloroform is unquestionably a more powerful agent than ether, and acts not only differently, but in a much smaller dose. The comparative smallness of its dose is certainly a ground of danger, when its administration falls into reckless or incompetent hands. In view of the greater danger from the use of chloroform as an anæsthetic, the governors of the Massachusetts General Hospital have prohibited the use of any other agent than ether in surgical operations.

When the effects of chloroform inhalation proceed too far, the remedies are a horizontal posture, cold air fanned upon the face, cold water poured upon the head, sinapisms to the feet, frictions and heat to the body and extremities, and ammonia to the nostrils. If respiration ceases, the tongue should be seized with the artery-forceps, and pulled forward from off the glottis, and artificial respiration attempted by blowing into the mouth, and by other appropriate measures. When the patient can swallow, strong coffee may be given with advantage. Galvanic electricity, passed through needles inserted in different parts of the body, is recommended by M. Abeille, of Ajaccio, as a powerful means of recalling sensibility; and it is highly probable that the electro-magnetic battery would prove useful. When an overdose is taken by the mouth, the same remedies may be employed, with the addition of the stomach-pump, when vomiting cannot be produced. In a case of suicide by swallowing chloroform, in which death took place in about thirty-four hours, the lining membrane of the larynx and trachea was found inflamed, the bronchi were loaded with a dirty-gray purulent fluid, the lungs were inflamed as in the first stage of pneumonia, and the brain and its membranes congested. In another fatal case, reported by Dr. J. Williams, of the Philadelphia Hospital, Blockley, in which the patient survived thirty-seven hours, no morbid appearances were observed worthy of note.

In relation to the preparations, consisting of chloroform and alcohol, which have been used under the name of "chloric ether," the reader is referred to *Spiritus Chloroformi* in *Part* II.*

* *Chlorodyn.* An empirical preparation under this name has been extensively used in London, and has recently acquired some general notoriety from having been the reputed cause of death in a case of accidental poisoning in England, and as having produced very threatening symptoms in another case, in which the patient was saved. OLEUM ÆTHEREUM. *U. S. Ethereal Oil.*

"Take of Stronger Alcohol *two pints;* Sulphuric Acid *sixty-one troyounces;* Distilled Water *a fluidounce;* Stronger Ether *a sufficient quantity.* Add the Acid slowly to the Alcohol, mix them thoroughly, and allow the mixture to stand for twelve hours. Decant the clear liquid from the sediment into a tubulated retort, of such capacity that the mixture shall nearly fill it. Adapt a thermometer tube to the tubulure by means of a cork, so that the bulb shall be deeply immersed in the liquid, and, having attached a Liebig's condenser, distil, by means of a sand-bath, at a temperature between 312° and 322°, until the liquid ceases to come over, or until a black froth begins to arise in the retort. Separate the yellow ethereal liquid from the distillate, and expose it for twenty-four hours, in a shallow capsule, to evaporate spontaneously. Then transfer the remaining liquid to a wet filter; and, when the watery portion has drained off, wash the oil which is left, while on the filter, with the Distilled Water. When this also has drained off, transfer the oil to a graduated measure, by perforating the point of the filter, and add to it an equal volume of Stronger Ether. The Ethereal Oil, obtained by this formula, measures about six fluidrachms." *U. S.*

In the late consolidation of the British Pharmacopœias, this valuable remedy was omitted, partly on account of the uncertainty as to its special antispasmodic virtues, partly from its expensiveness when properly made and its liability to spontaneous change, and partly, moreover, because not only is it often adulterated, but other compounds are substituted for it. (*Med. Times and Gaz*, March, 1864, p. 248.) It is, however, retained in the U. S. Pharmacopœia, with certain modifications in the process, which, it is hoped, may enable it to yield a larger and more reliable product.

In the existing U. S. formula, the first change to be noticed is the direction, after the mixture of the acid and alcohol, to decant the clear liquid from the sediment, which is sulphate of lead, deposited by the acid on account of its dilution. According to Dr. Squibb, the presence of the sulphate of lead in the retort causes the mixture to froth over, and thus necessitate a suspension of the process so much sooner, as greatly to lessen the amount of product the materials are capable of affording. The increase of oil resulting from this simple modification of the process is said to be one-third. Another new feature is the introduction of a thermometer into the retort, whereby the important point is obtained of properly regulating the temperature, which, in order to the due reaction of the materials, should not fall below 312° nor rise above 322°. Again, the washing of the oil with solution of potassa has been omitted, because the alkali was found to decompose a portion of the oil, and the sulphurous acid, which it was intended to neutralize, can be separated by the washing with distilled water now directed. By wetting the filter, the oil is prevented from passing along with the water. Finally, the oil is now ordered to be diluted with an equal measure of stronger ether, as this has been found to contribute greatly to its preservation.

When alcohol is distilled with a large excess of sulphuric acid, the same products are generated as those mentioned, in the article upon ether, as being formed towards the close of the distillation of that liquid. (See *page* 988.) These were stated to be sulphurous acid, heavy oil of wine, olefiant gas, and resino-carbonaceous matter. In the U. S. process such an excess of sulphuric acid is

ula published in the *Am. Journ. of Pharm.*, March, 1860 (p. 181), it would appear to consist of chloroform, chloric ether (so called), tincture of capsicum, oil of peppermint, muriate of morphia, hydrocyanic acid (Scheele's), perchloric acid, tincture of Indian hemp, and molasses; and of these powerful medicines, moreover, in such proportions as to make one shudder at the idea of its unregulated use. (*Note to the twelfth edition.*)

Other formulas for this nostrum will be found in the *American Journal of Pharmacy* (Jan. 1865, p. 17), and in the same journal for May, 1868, p. 210. (*Note to the thirteenth edition.*)

employed for the purpose of obtaining the oil. The product of the distillation is generally in two layers, one, consisting of water holding sulphurous acid in solution, and the other, of ether containing the heavy oil of wine. According to the experience of Dr. Squibb, the sp. gr. of these two layers is so nearly equal, that sometimes one and sometimes the other is uppermost; so that the direction in the old formula to separate the supernatant liquor is incorrect, and has been superseded by the present, to separate the yellow ethereal liquid; the colour and other sensible properties being considered sufficiently distinctive. After separation, the liquid is exposed for twenty-four hours to the air, in order to dissipate the ether by evaporation; and the oil which is left is washed with water to deprive it of all traces of sulphurous acid.

The nature and mode of formation of heavy oil of wine are not well understood. It has been explained, in a preceding article, that, in the early stage of the distillation of a mixture of sulphuric acid and alcohol, sulphovinic acid, or the double sulphate of ether and water, is formed. During its progress this is decomposed so as to yield ether. When, however, the alcohol is distilled with a large excess of sulphuric acid, the sulphovinic acid is decomposed so as to form a small quantity of the heavy oil of wine, now considered to be a double sulphate of ether and ethylen, having the formula $C_4H_5O,SO_3+C_4H_4,SO_3$. It is conceived to be generated from two eqs. of sulphovinic acid (double sulphate of ether and water), which are resolved into one eq. of heavy oil of wine, two of sulphuric acid, and three of water. When the heavy oil is gently heated with four parts of water, sulphovinic acid is reproduced, and the separated ethylen floats on the surface as an oily substance, called, when thus isolated, light oil of wine. *Light oil of wine*, as thus obtained, is a pale-yellow oil, supposed to have the formula C_4H_4. As ordinarily procured in the process for preparing ether, it contains a portion of that substance. When the pure light oil of wine is kept, it deposits a stearoptene, isomeric with itself, called concrete oil of wine, or oil of wine camphor; after which the oil is changed, and takes the name of etherole. *Etherole* is a pale-yellow oily liquid, having an aromatic odour. Its sp. gr. is 0·921, boiling point 536°, and freezing point 31° below zero. It communicates a greasy stain to paper. *Concrete oil of wine*, sometimes called *etherine*, crystallizes in long, transparent, brilliant, tasteless prisms, soluble in alcohol and ether, insoluble in water, fusible at 230°, boiling at 500°, and having the sp. gr. 0·980. Dr. Squibb takes a different view of the composition of ethereal oil, and believes it, instead of a sulphate or double sulphate, to be a sulphovinate of a carbohydrogen base; and for this reason, that it fails, especially when pure and recent, to give any of the characteristic reactions of sulphuric acid or the sulphates. (*Am. Journ. of Pharm.*, Jan. 1861, p. 58.)*

Properties. The undiluted *ethereal oil* (*heavy oil of wine*) is a yellowish neutral liquid, possessing an oleaginous consistency, a penetrating aromatic odour, and rather sharp and bitter taste. It boils at 536°. Its sp. gr. is, according to the U. S. Pharmacopœia of 1850, 1·096; according to the London College, after Mr. Hennell's results, 1·05. The density obtained by Dr. Squibb, U. S. Navy, by following the old formula of the U. S. Pharmacopœia exactly, was 1·129. By Dumas and Serullas its density is stated to be as high as 1·133, which is probably the more correct number for the *pure* oil. When dropped into water it sinks, assuming the form of a globule. It dissolves sparingly in cold water,

* Valuable papers have been contributed by Mr. C. Lewis Diehl and Prof. John M. Maisch, on this officinal preparation; the former to the *Proceedings of the American Pharmaceutical Association* for 1864; the latter to the *American Journal of Pharmacy* (March, 1865, p. 160), to which we refer those especially concerned in its manufacture. In Mr. Diehl's paper valuable suggestions are made in reference to the mode of reheating so as properly to regulate the temperature. An important practical fact is stated by Prof. Maisch, that the ethereal oil, in contact with water, undergoes a decomposition into light oil of wine and sulphovinic acid, rapidly and completely if the water is hot or if solution of an alkali or alkaline carbonate is used, and more slowly with cold water. Hence the inference that the washing of the ethereal oil, directed at the close of the U. S. process, should be completed as rapidly as possible. (*Note to the thirteenth edition.*)

moderately in hot water, and readily in alcohol and ether. It is devoid of acid reaction, the sulphuric acid present in it being completely neutralized by the ether and ethylen united with it. The sulphuric acid present is not precipitated by the usual reagents for this acid; because they furnish a base, which, replacing the ethylen, gives rise to one of the salts of sulphovinic acid, all of which are soluble in water and hydrous alcohol. The U. S. ethereal oil of the existing Pharmacopœia is the proper oil diluted with an equal volume of stronger ether. This gives it an ethereal odour in addition to that characteristic of the pure oil, and considerably reduces its sp. gr., which is now stated at 0·91. The process by which the officinal oil of wine is formed yields but a small product, being, according to the Pharmacopœia, only about six fluidrachms, or somewhat more than a fortieth, by measure, of the alcohol employed.

In the officinal ethereal oil, the heavy oil of wine, that is, the double sulphate of ether and ethylen, is not only diluted with an equal measure of ether, but is mixed also with variable proportions of free light oil of wine (ethylen), in addition to that present in it as one of the essential constituents of the heavy oil This fact accounts for the different densities assigned to the heavy oil.

The heavy oil undiluted is liable to spontaneous change by time, being not only rendered brown, but chemically altered so as to separate into two layers. But this tendency is in great measure obviated, in the officinal ethereal oil, by the preservative influence of the ether. It may be kept long without other appreciable change than the acquisition of a brown hue, which does not interfere with its medical virtues. It should not, when tested by dry litmus paper, evince the presence of any free acid.

The article, sold in our shops as ethereal oil, is too often a mixture of alcohol and ether, containing but a trace of the oil. Four samples of so-called ethereal oil, as imported from England, were examined by Mr. E. N. Kent, of New York, and found to have the composition above stated. (*N. Y. Journ. of Pharm.*, i. 65.) The ethereal oil is used only for the preparation of the Compound Spirit of Ether or Hoffmann's anodyne, which, when properly made, is a very valuable medicine; and it is much to be regretted that due attention has not been paid by the manufacturing chemists to the furnishing of a good ethereal oil to the apothecary. It is necessarily an expensive preparation; but this does not justify the substitution for it of a cheaper and nearly worthless article under the same name.

ALOE.

Preparation of Aloes.

ALOE PURIFICATA. *U. S. Purified Aloes.*

"Take of Socotrine Aloes *twenty-four troyounces;* Stronger Alcohol *four fluidounces.* Heat the aloes, by means of a water-bath, until it is completely melted. Then add the Alcohol, and, having stirred the mixture thoroughly, strain it through a fine sieve, which has just been dipped into boiling water. Evaporate the strained mixture by means of a water-bath, constantly stirring, until a thread of the liquid becomes brittle on cooling. Lastly, break the product when cold into pieces of a convenient size, and keep it in a well stopped bottle." *U. S.*

Aloes, even of good quality, is so often mixed as found in the market with various accidental impurities, such as fragments of wood, vegetable remains, pieces of leather, and earthy matter, that it has been thought advisable to have an officinal process by which it may be freed from these, should its purification be found necessary in any particular instance. This is especially the case with Socotrine aloes, which, from the want of proper supervision in its preparation, is probably more liable to these impurities than the Cape or Barbadoes aloes; but, as these are also sometimes impure, there seems to be no good reason why they should have been officinally excluded from the benefits of the process.

The use of alcohol in the formula is simply to render the melted aloes more liquid, and thus facilitate the straining; and it is subsequently got rid of by evaporation; but care should be taken not to use too great a heat, or to continue it too long, for fear of impairing the virtues of the drug.

Thus prepared, aloes is in angular fragments, brittle, of a brownish or reddish-brown colour, and of the agreeable aromatic odour of Socotrine aloes. It is nearly all soluble in alcohol. W.

ALUMEN.

Preparations of Alum.

ALUMEN EXSICCATUM. *U. S., Br. Dried Alum.*

"Take of Alum, in coarse powder, *four troyounces*. Expose it, in a suitable vessel, to a temperature not exceeding 450° until the residue weighs two troyounces and one hundred and twenty grains; then reduce it when cold to fine powder." *U. S.*

"Take of Alum *four ounces*. Heat the Alum in a porcelain dish, or other suitable vessel, till it liquefies, then raise and continue the heat, not allowing it to exceed 400°, till aqueous vapour ceases to be disengaged, and the salt has lost 47 per cent. of its weight. Reduce the residue to powder, and preserve it in a well-stopped bottle." *Br.*

The object of these processes is to obtain the alum free from its water of crystallization, without otherwise in the least decomposing it. For this purpose a certain degree of heat is necessary; and yet, if the heat be too great, the salt itself is decomposed, and the desired end is not attained. If the alum employed be the potassa-alum, the old indefinite directions will generally be sufficient to secure the requisite result, as this salt will resist a heat short of redness; but this is not the case with the ammonia-alum, which, on account of its greater cheapness, has almost excluded the former salt from the market, and, there is reason to apprehend, may sometimes be substituted for the potassa-alum, though this is the one officinally directed. To guard against failure from this cause, the U. S. Pharmacopœia now prescribes 450° as the highest heat to be employed, and checks the operation when nearly all the water has been driven off, as indicated by the weight of the residue. Mr. John M. Maisch has satisfactorily determined by experiment that, whichever alum may be used, this temperature is quite high enough; and the direction of the Pharmacopœia, as to the weight of the residue, ensures that a sufficient heat will be employed. By the officinal process half a drachm or about 4 per cent. of the water of crystallization, supposing the salt employed to be the potassa-alum, is left behind; and Mr. Maisch has ascertained that this in no degree injures the properties of the dried salt. (*Am. Journ. of Pharm.*, Jan. 1860, p. 21.) In the case of the ammonia-alum, as this salt contains a somewhat larger proportion of water, the limitation as to the quantity expelled still further secures against the employment of too great a heat.

Properties. Dried alum, sometimes called *alumen ustum* or *burnt alum*, is in the form of an opaque white powder, possessing a more astringent taste than the crystallized salt. Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, alum loses from 41 to 46 per cent. of its weight in dissipated water. Dried alum resists the action of water for a long time, showing its altered aggregation. It is, however, if properly prepared, at length wholly dissolved by cold water, while 6 parts of boiling water dissolve it in a short time; and this may be considered as a sufficient test that the salt has not been decomposed. (*Maisch.*) In composition it differs from crystallized alum merely in the absence of water.

Medical Properties and Uses. Dried alum has been given in obstinate constipation, with the effect of gently moving the bowels, and affording great relief from pain. (See *Alumen.*) The dose is from five to ten grains or more. Its principal medical use is as an escharotic for destroying fungous flesh. B.

ALUMINÆ SULPHAS. *U. S.* *Sulphate of Alumina.*

"Take of Sulphate of Alumina and Ammonia, Carbonate of Soda, each, *four troyounces;* Sulphuric Acid *a troyounce and one hundred and fifty grains;* Water *a sufficient quantity.* Dissolve the salts separately, each in six fluidounces of boiling Water, and pour the solution of the Sulphate gradually into that of the Carbonate; then digest with a gentle heat until the evolution of carbonic acid ceases. Collect upon a filter the precipitate formed, and wash it with water until the washings are no longer affected by chloride of barium. Next, with the aid of heat, dissolve the precipitate in the Sulphuric Acid, previously diluted with half a pint of Water, and, having filtered the solution, evaporate it until a pellicle begins to form. Then remove it to a water-bath, and continue the evaporation, with constant stirring, until a dry salt remains. Lastly, preserve this in a well-stopped bottle." *U. S.*

In the above process it is the ammonia-alum that is used. The soda of the carbonate unites with the sulphuric acid of the tersulphate of alumina, with the escape of the carbonic acid, and the precipitation of the alumina in the form of a hydrate; while the undecomposed sulphate of ammonia of the alum, and the newly formed sulphate of soda, remain in solution. The alumina is then washed in order to separate any portion of the sulphates adhering to it, the absence of which is shown by the non-action of chloride of barium on the washings. It now remains to unite the hydrate of alumina and sulphuric acid, which is effected by heating them with water; and the salt, which is formed in solution, is obtained by evaporating the solution to dryness. It may also be obtained from the solution by the addition of alcohol, which precipitates it. In the process the several substances are used in very nearly saturating proportions.

Sulphate of alumina may be prepared also by the process of MM. Huria and Brunel, which consists in exposing, in an iron cylinder, sulphate of alumina and ammonia (ammonia-alum), first dried to separate its water of crystallization, to a cherry-red heat. Sulphate of alumina remains in the cylinder, and the volatilized products are collected in water. The chief of these is sulphite of ammonia, which serves for the preparation of a fresh portion of alum, after having been changed into the sulphate by oxidation in the air. (*Chem. Gaz.*, Sept. 15, 1852, p. 359.)

Properties. As procured by the officinal process, sulphate of alumina is in the form of a white powder. It may, however, be obtained in lamellar crystals. As seen in commerce, it is usually in flattened crystalline cakes, which appear as though formed by the cooling of soft masses of minute crystals. It has a sour, as well as sweet and very astringent taste, is soluble in twice its weight of water, and has an acid reaction. It consists of one eq. of alumina, which is a sesquioxide of aluminium, and three eqs. of sulphuric acid ($Al_2O_3 3SO_3$), and, when crystallized, contains 18 eqs. of water. The salt is, therefore, a tersulphate of alumina. It is known to be a sulphate by giving a precipitate with chloride of barium insoluble in nitric acid, and a salt of alumina by forming octohedral crystals of alum when its solution is evaporated with sulphate of potassa or ammonia. In consequence of its strong affinity for potassa, it is coming into use in the arts as a means of separating that alkali. (*Waltl.*)

Medical Properties and Uses. This salt is used only externally, as an astringent and antiseptic. The salts of alumina generally have the property of opposing animal putrefaction; but the sulphate is practically preferred. It has been used extensively in the Philadelphia Hospital, Blockley, at the suggestion of Dr. Dunglison, as an antiseptic and detergent application to ulcers, and with favourable results. The late Dr. Pennypacker reported several cases in which it proved useful. The strength of the solution employed varied from ʒijss to ʒiij of the salt to fʒvi of water, according to the state of the ulcer. Dr. G. Johnson, of Georgia, found the solution attended with the happiest effects, used as an injection in fetid discharges from the vagina. (*Med. Exam.*, vi. 63 and 112.) M. Homolle employs a saturated solution with much advantage as a mild caustic in enlarged tonsils, nasal polypi, nævi, scrofulous and cancerous ulcers, diseases

of the os uteri, and various chronic enlargements. He applies it daily by means of a hair pencil. He has sometimes found the solution to answer still better by the addition of oxide of zinc. Solution of sulphate of alumina is capable of dissolving a considerable quantity of recently precipitated gelatinous alumina. Such a solution, impregnated with benzoin, has been proposed by M. Mentel as a hemostatic, under the name of *benzinated solution of alumina.* It resembles the styptic liquid of Pagliari. (See *page* 174.) It is prepared by saturating, with gelatinous alumina, a solution made of eight ounces of sulphate of alumina dissolved in a pint of water. To the saturated solution six drachms of bruised amygdaloid benzoin are added, and the whole is kept at a temperature of about 150° for six hours, with occasional agitation; so that the liquid, after filtration, may have about the density 1·26. This liquid, put in a cool place for several days, so as to deposit some crystals of alum, forms the benzinated solution, remarkable for its very sweet odour, and astringent balsamic taste. Benzinated solution of alumina, diluted in the proportion of from two to five fluidrachms to the pint of water, has been found useful as an injection in leucorrhœa, and in ulcerations of the neck of the uterus, accompanied by fetid discharges. (See *Am. Journ. of Pharm.*, March, 1857, p. 128.)

The aqueous solution of sulphate of alumina was found by M. Gannal to be effectual in preserving bodies for dissection, when injected into the blood-vessels. In summer the bodies were preserved fresh for twenty days or more; in winter, for three months. For use in winter, a quantity of the solution, sufficient for injecting one body, may be made by adding a pound, avoirdupois, of the salt to a quart of water; in warm weather, the solution must be stronger. B.

AMMONIA.

Preparations of Ammonia.

In the present edition of the U. S. Pharmacopœia, all the liquid preparations of ammonia are arranged under other heads; and we follow the example of that work in making a similar disposition of them here. Hence, the reader will find the *Water of Ammonia* (Solution of Ammonia, U. S. 1850) under the AQUÆ or *Waters; Solution of Acetate of Ammonia* under the LIQUORES or *Solutions;* and the *Spirit* and *Aromatic Spirit of Ammonia* under the SPIRITUS or *Spirits.*

AMMONIÆ BENZOAS. *Br. Benzoate of Ammonia.*

"Take of Solution of Ammonia *three fluidounces* [Imperial measure], or *a sufficiency;* Benzoic Acid *two ounces* [avoirdupois]; Distilled Water *four fluidounces.* Dissolve the Benzoic Acid in three fluidounces of Solution of Ammonia previously mixed with the Water; evaporate at a gentle heat, keeping ammonia in slight excess; and set aside that crystals may form." *Br.*

Although the amount of ammonia ordered in the formula is in excess, yet, from the feeble affinity between the constituents, and the consequent escape of ammonia during the evaporation, a portion of the acid benzoate would be formed, if it were not that a little solution of ammonia is from time to time added during or near the close of the evaporation, so as to maintain the alkali in slight excess. In the process of the Pharmacopœia of 1864, this direction was not given, and the result was consequently defective. The crystals, for the same reason, should be dried without heat. Professor Procter informed us that half the quantity of water, eight fluidounces, originally directed in the formula, moderately heated, readily dissolves the acid after the addition of ammonia, and, on cooling, deposits crystals of the benzoate. In conformity with this opinion, the quantity of water has been reduced in the present formula to four fluidounces. If slightly evaporated, and then allowed to cool, the solution becomes a mass of crystals, retaining so much water as to render it necessary to dry them by bibulous paper.

Properties. A specimen of this salt, prepared at our request by Prof. Procter, in accordance with the directions of the Br. Pharmacopœia, is in minute white, glistening, extremely thin four-sided laminæ, having a slight odour of

officinal benzoic acid, and a bitter, saline, somewhat balsamic taste, leaving a slight but persistent sense of acrimony on the tongue. The salt is soluble in water and alcohol, and when heated sublimes without residue; but is probably changed into the acid benzoate. Gmelin states that, if the solution be boiled, the salt is converted into the acid benzoate, which crystallizes in feathery tufts of needles. (*Handbook*, xii. 38.) According to Lichtenstein, it deliquesces in the air. It consists of one eq of ammonia, one of benzoic acid, and two eqs. of water; one of the eqs of water being derived from the acid and the other from the base, so that its formula is $NH_3,C_{14}H_5O_3+2HO$. But the Br. Pharmacopœia, considering hydrated ammonia as oxide of ammonium, gives the formula NH_4O, $C_{14}H_5O_3$. It gives a copious yellow precipitate with the salts of sesquioxide of iron: and is known to contain benzoic acid and ammonia, by depositing the former when the solution is acidulated with muriatic acid, and giving off the latter when it is heated with potassa. (*Br.*) According to Mr. Squire, it is the acid salt that is commonly met with in the shops, which is less soluble than the officinal salt, requiring 60 parts of water and 12 of alcohol for solution. This is a decided objection to it.

Medical Properties and Uses. Benzoate of ammonia is a slightly stimulant diuretic, but acts chiefly through its benzoic acid, being decomposed by the gastric acids, which combine with the ammonia, while the benzoic acid is absorbed, and passes out through the kidneys in the form of hippuric acid. Under benzoic acid, it has been stated that the proportion of urea is diminished at the same time, giving rise to the supposition that the nitrogen of the hippuric acid is derived from that source. Dr. Garrod suggests that, as the elements of hippuric acid are the same as those of benzoic acid and glycocoll, the hippuric acid may be formed by a direct combination of these substances. The salt has been found useful as a diuretic in defective action of the kidneys, as an alterative to the mucous membrane of the urinary passages in chronic inflammation of that tissue, and as a solvent of the phosphatic deposits, through the hippuric acid into which it is converted. It has been employed in gouty affections with a view to the removal of the deposits of urate of soda about the joints; but it has been shown to have no effect on the elimination of uric acid. The salt does not appear to produce any injurious effects even in considerable quantities. (Garrod, *Med. Times and Gaz.*, Feb. 1864, p. 146.) The dose is from 10 to 30 grains, which may be taken dissolved in water. W.

AMMONIÆ PHOSPHAS. *Br. Phosphate of Ammonia.*

"Take of Diluted Phosphoric Acid *twenty fluidounces;* Strong Solution of Ammonia *a sufficiency.* Add the Ammonia to the Phosphoric Acid, until the solution is slightly alkaline, then evaporate the liquid, adding more Ammonia from time to time, so as to keep it in slight excess, and when crystals are formed on the cooling of the solution, dry them quickly on filtering paper placed on a porous tile, and preserve them in a stoppered bottle." *Br.*

This, like the preceding salt of ammonia, is a new officinal of the Br. Pharmacopœia. The process differs somewhat from that of the Pharmacopœia of 1864, though aiming at the same result. The salt is formed by the direct union of its constituents. In the former process the mother-waters were made to yield an additional portion of the salt by the addition of more solution of ammonia; but this provision has been abandoned in the present edition of the Pharmacopœia. The variety of phosphoric acid employed in this formula is the tribasic, which forms three salts with ammonia, one containing 3 eqs. of ammonia without basic water, which may be called the subphosphate, the second, two eqs. of ammonia and one of basic water, forming the neutral phosphate, and the third, one eq. of ammonia and two of basic water, forming the acid phosphate. The second of these is the one intended by the British Council, and is represented by the formula $2NH_4O,HO,PO_5$. To prepare it, a constant excess of ammonia must be maintained, and this is done by compliance with the process, if the materials are of due strength. Without such a precaution, more or

less of acid phosphate would be generated, in consequence of the escape of the alkali.

Properties. The officinal salt of the Br. Pharmacopœia is in transparent colourless prisms, soluble in water, and insoluble in alcohol. When heated with caustic potassa it evolves ammonia; and a solution of it gives with nitrate of silver a yellow precipitate, indicating that the acid is the tribasic phosphoric acid. "If 20 grains be dissolved in water, and solution of ammonio-sulphate of magnesia be added, a crystalline precipitate falls, which, when well washed on a filter with solution of ammonia, diluted with an equal volume of water, dried, and heated to redness, leaves 16·08 grains." (*Br.*) The residue is pyrophosphate of magnesia, and its amount indicates the quantity of phosphoric acid contained in the salt.

The foregoing description is that given of its salt by the Br. Pharmacopœia; but it does not exactly correspond with that of the neutral salt ordinarily received, leading to the inference that it may be a mixture. The salt commonly found in the shops is either the neutral or acid phosphate, or a mixture of the two. The neutral salt ($2NH_4O,HO,PO_5+HO$) may be made by saturating the excess of acid in superphosphate of lime by means of carbonate of ammonia. Phosphate of lime is precipitated, and phosphate of ammonia obtained in solution, which, being duly concentrated by a gentle heat, affords the salt in crystals upon cooling. The method of obtaining the superphosphate of lime is given under the head of phosphate of soda. (See *Sodæ Phosphas.*) This variety of phosphate of ammonia is a white salt, crystallizing in six-sided tables, derived from oblique quadrangular prisms, efflorescent, soluble in alcohol, and in 4 parts of cold water. The solution has an alkaline somewhat saline taste, and an alkaline reaction, and gives out ammonia when heated. (Bridges, *Fownes' Chem.*, Am. ed., p. 234.)

The acid phosphate ($NH_4O,2HO,PO_5+4HO$) is obtained by boiling a solution of either of the other salts so long as ammonia escapes, and then crystallizing. Its crystals are four-sided prisms, permanent in the air, of an acid taste and reaction, and soluble in 5 parts of cold water. (*Bridges.*) In a specimen of the common phosphate of ammonia of the shops which came under our notice, we recognised both the tabular crystals of the neutral phosphate with two eqs. of ammonia, having a saline slightly acrid taste, and neutral in reaction, and the prism of the acid salt, with a sour and saline taste and decided acid reaction. W.

Medical Properties and Uses. This salt was first brought to the notice of the profession, as a remedy for gout and rheumatism, by Dr. T. H. Buckler, of Baltimore, in a paper published in the *Am. Journal of the Medical Sciences* for Jan. 1846. In this paper a number of cases of these diseases are reported, which were treated mainly by this remedy by Dr. Buckler and several of his medical friends, and with apparently good effects. Dr. Buckler was led to employ the salt on theoretical grounds. He conceived that the "matter of gout" consisted of two salts, the urates of soda and lime, existing in the blood; and that the phosphate of ammonia, by reacting with them, would give rise to soluble salts. The new salts formed, if the double decomposition should take place, would be urate of ammonia, and the phosphates of soda and lime. Unfortunately for this theory, as furnishing the means of eliminating uric acid, urate of ammonia is not more soluble than urate of soda. Nevertheless, apart from all theory, the therapeutic powers of phosphate of ammonia deserve to be investigated. Since the publication of Dr. Buckler's paper, several practitioners, both in this country and in Europe, have employed the remedy with apparently useful results in chronic gout, and certain urinary diseases. The dose of the salt is from ten to forty grains, three or four times a day, dissolved in a tablespoonful of water. B.

AMMONIÆ VALERIANAS. *U.S. Valerianate of Ammonia.*

"Take of Valerianic Acid *four fluidounces.* From a mixture, placed in a suitable vessel, of Muriate of Ammonia, in coarse powder, and an equal weight of Lime, previously slaked and in powder, obtain gaseous ammonia, and cause

it to pass, first through a bottle filled with pieces of Lime, and afterwards into the Valerianic Acid, contained in a tall, narrow, glass vessel, until the Acid is neutralized. Then discontinue the process, and set the vessel aside that the Valerianate of Ammonia may crystallize. Lastly, break the salt into pieces, drain it in a glass funnel, dry it on bibulous paper, and keep it in a well-stopped bottle." *U. S.*

This is a new officinal of the U. S. Pharmacopœia. Much difficulty was experienced by manufacturing chemists in procuring crystallized valerianate of ammonia, until, after a series of experiments, Mr. B. J. Crew, of Philadelphia, ascertained that it was necessary to employ the monohydrated valerianic acid, as the ordinary acid with three eqs. of water could not be successfully employed for the purpose. The officinal formula is based upon that of Mr. Crew, published in the *Am. Journ. of Pharm.* (March, 1860, p. 109). In this formula the monohydrated valerianic acid, procured by a special process (see *Acidum Valerianicum*, page 981), is saturated with gaseous ammonia obtained in the usual manner from a mixture of muriate of ammonia and lime. The saturation is known to have been effected when litmus paper is no longer acted on. During the operation heat is developed sufficient to prevent premature crystallization, and, when the saturation is completed, nothing more is necessary than to allow the solution to cool. Crystallization soon begins, and in a few hours the contents of the vessel become a nearly solid mass of crystals.

Properties. Thus prepared, valerianate of ammonia is in snow-white, pearly, four-sided, tabular crystals, perfectly dry, of an offensive odour like that of valerianic acid, and a sharp sweetish taste. Instead of deliquescing, whenever exposed to the air, as happened to the salt formerly procured, it undergoes this change only in a moist atmosphere, and effloresces when the air is dry. It is very soluble both in water and alcohol. Exposed to heat it is in great measure volatilized unchanged; but a small portion, by giving off a part of its ammonia, is converted into the acid valerianate. Its formula, viewed as a salt of hydrated ammonia, is $NH_3HO,C_{10}H_9O_3$, as a salt of oxide of ammonium NH_4O, $C_{10}H_9O_3$. It is known to be a salt of ammonia by giving off this gas when treated with potassa, and of valerianic acid by the separation of this acid, and its appearance on the surface in the form of an oil, when the salt is decomposed in solution by a mineral acid. W.

Medical Properties. Valerianate of ammonia is not poisonous. Given to dogs in the dose of 150 grains, it produced no inconvenience. As a therapeutic agent it was first brought to the notice of the profession, in 1856, by M. Déclat, of Paris, who published a paper in that year, going to show its remarkable efficacy in the treatment of neuralgia. The preparation which he used was a solution of valerianate of ammonia of uniform strength, made according to the recipe of M. Pierlot, an apothecary of Paris, which had been extensively given to the epileptics of the Salpêtrière and the Bicêtre. Since then it has been used in various diseases, principally of the nervous system; such as hysteria, epilepsy, chorea, &c. The favourable report of its efficacy in neuralgia, made by M. Déclat, has been confirmed by practitioners in Paris, London, and Dublin. The dose of the salt is from two to eight grains, dissolved in water. As now prepared, it may be made into pills without inconvenience; and, properly coated so as to conceal their disagreeable odour, they are probably the best form for the administration of the salt. M. Pierlot made his solution, mentioned above, by dissolving *a drachm* of valerianic acid in *thirty-two drachms* of distilled water, saturating the solution with carbonate of ammonia, and adding to the salt formed, *two scruples* of the alcoholic extract of valerian. According to M. Pierlot, the latter addition is necessary in order to preserve the preparation from change; for a simple solution of the ammoniacal salt is rapidly decomposed. It will keep still better if the extract, when added to the solution, be mixed with a fluidounce of diluted alcohol, while but 24 drachms of distilled water are used, so as to preserve the measure. The solution of M. Pierlot is neutral, of a brown colour, and a strong odour of valerian. It contains 1-25th of its weight of the

pure salt. The dose is from six to thirty drops, given in water or on a lump of sugar. (*Ann. de Thérap.*, 1857, p. 55.)* B.

ANTIMONIUM.

Preparations of Antimony.

In arranging the Preparations of Antimony, it has been deemed expedient to follow the example of the Pharmacopœias, in placing them in a strictly alphabetical order; and, as relates to the *Solution of Terchloride of Antimony* and the *Wine of Antimony*, to obey the same authority in transferring them, the one to the *Solutions*, the other to the *Wines*, where they properly belong through the character of their menstrua.

ANTIMONII ET POTASSÆ TARTRAS. *U. S.* ANTIMONIUM TARTARATUM. *Br.* ANTIMONIUM TARTARIZATUM. *Ed., Dub. Tartrate of Antimony and Potassa. Tartarated Antimony. Tartarized Antimony. Tartar Emetic.*

"Take of Oxide of Antimony, in very fine powder, *two troyounces;* Bitartrate of Potassa, in very fine powder, *two troyounces and a half;* Distilled Water *eighteen fluidounces.* To the Water, heated to the boiling point in a glass vessel, add the powders, previously mixed, and boil for an hour; then filter the liquid while hot, and set it aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stopped bottle. By further evaporation the mother-water may be made to yield more crystals, which should be purified by a second crystallization." *U. S.*

"Take of Oxide of Antimony *five ounces* [avoirdupois]; Acid Tartrate of Potash, in fine powder, *six ounces* [avoird.]; Distilled Water *two pints* [Imperial measure]. Mix the Oxide of Antimony and Acid Tartrate of Potash with sufficient Distilled Water to form a paste, and set aside for twenty-four hours. Then add the remainder of the Water and boil for a quarter of an hour, stirring frequently. Filter, and set aside the clear filtrate to crystallize. Pour off the mother-liquor, evaporate to one-third, and set aside that more crystals may form. Dry the crystals on filtering paper at the temperature of the air." *Br.*

This preparation is a double salt, consisting of tartrate of potassa, united with tartrate of teroxide of antimony. The principle of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate (cream of tartar) with the teroxide. The officinal processes consist in boiling a mixture of cream of tartar and of pure teroxide obtained by a distinct process. (See *Antimonii Oxidum.*) This conforms with the formula of the late Dublin Pharmacopœia, and is an improvement of the U. S. formula of 1850, in which the *oxychloride of Antimony, or powder of Algaroth*, was the form of oxide used, and was prepared from the sulphuret as the first step of the process.

In the late London formula the teroxide used was in the form of disulphate of antimony, which was originally proposed by the late Mr. Phillips, so early as 1811. It was prepared in the following manner. By gently heating sulphuric acid with tersulphuret of antimony, the metal was teroxidized at the expense of part of the acid, sulphurous acid was evolved, and sulphur set free. By gradually increasing the heat until dryness was produced, the whole of the sulphurous acid was driven off, the free sulphur was burnt out, and nothing remained but the teroxide, united with sulphuric acid in the form of tersulphate of teroxide of antimony. This, by continued washing, was converted into the anhydrous disulphate of the teroxide ($2SbO_3,SO_3$). (*Phillips.*) The disulphate was then

* *Elixir of Valerianate of Ammonia.* Various attempts have been made to prepare a formula for the exhibition of valerianate of ammonia, which shall in some measure cover its offensiveness. The following, which has been considerably used in this city, under the name above given, is perhaps as suitable as any that has been proposed. Take of Valerianate of Ammonia ʒi; Fluid Extract of Vanilla fʒss; Compound Tincture of Cardamom fʒvi; Curaçoa fʒij; Water fʒiv. Mix. Dose, a teaspoonful three times a day

mixed with cream of tartar in the proportion of nine parts by weight to ten, and the mixture boiled with water in the usual manner. This process is an eligible one, and has the merit of being economical. According to Mr. Phillips, it affords "a very pure and beautiful salt."

In the preparation of tartar emetic several circumstances should be taken into view. The cream of tartar should not be in excess; as in that case it is apt to crystallize, upon cooling, with the tartar emetic. To avoid such a result it is better to have a slight excess of antimonial oxide. No rule is applicable to the determination of the proper proportion of water, except that it should be sufficient to dissolve the tartar emetic formed. The hot filtration, directed in the U. S. Pharmacopœia, may be conveniently performed by means of the tin apparatus, devised by Dr. Hare for filtering liquids at the point of ebullition. (See *page* 917.) The U. S. Pharmacopœia boils for an hour; the British for fifteen minutes. In all cases the salt should be obtained in well-defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.

It is not easy to decide as to the relative eligibility of the different forms of antimonial oxide, used for preparing tartar emetic. The preference, however, was given to the oxychloride (*powder of Algaroth*) by Berzelius; and M. Henry, an eminent pharmaceutist of Paris, after a careful comparison of the different processes, declared also in its favour. This testimony in favour of the oxychloride induced the revisers of our national Pharmacopœia, in 1830, to adopt it for making tartar emetic; but it was abandoned at the late revision, and the pure oxide was adopted in its place, in conformity with the Dublin formula, which is that of the Br. Pharmacopœia; so that the two Pharmacopœias are in accordance in the mode of preparing this important salt.

M. Henry has given a process for preparing tartar emetic with the oxychloride on a large scale; and, as his formula may be useful to the manufacturing chemist, we subjoin it, turning the French weights into the nearest *apothecaries'* weights and measures. Take of prepared sulphuret of antimony, in very fine powder, three pounds four ounces; muriatic acid, marking 22° (sp. gr. 1·178), eighteen pounds and a half; nitric acid, two ounces and a half. Introduce the sulphuret into a glass matrass, of a capacity double the volume of the mixture to be formed; and add to it from three to five pounds of the acids previously mixed, so that the sulphuret may be thoroughly penetrated by them; then add the remainder of the acids. Place the matrass on a sand-bath, and heat the mixture gradually to ebullition, avoiding the vapours, which are disengaged in large quantity. Continue the heat until the vapours given off are so far deprived of sulphuretted hydrogen as not to blacken white paper moistened with solution of acetate of lead; after which allow the liquor to cool, and to remain at rest until it has become clear. Decant the clear liquor, and, in order to procure the portion of liquid which may be retained by the moist residue, add to this a small portion of muriatic acid, and again decant. Mix the decanted liquids, which consist of a solution of terchloride of antimony, and add them to a large quantity of water, in order that the oxychloride may be precipitated; taking care, during their addition, to stir constantly in order that the precipitated powder may be more minutely divided, to facilitate its subsequent washing. To determine whether the water has been sufficient to decompose the whole of the terchloride, a part of the supernatant liquid, after the subsidence of the powder, is to be added to a fresh portion of water; and, if a precipitate take place, more water must be added to the mixture, so as to obtain the largest possible product of oxychloride. The precipitation being completely effected, wash the powder repeatedly with water, until this no longer affects litmus, and place it on linen to drain for twenty-four hours. The quantity of oxychloride thus obtained will be about three pounds and a half in the moist state, or two pounds nine ounces when dry. Assuming it to be this quantity, mix it with three pounds eleven

ounces of cream of tartar, in fine powder, and add the mixture to two gallons and five pints of boiling water, contained in an iron kettle. Concentrate the liquor rapidly until it marks 25° of Baumé's hydrometer for salts, and then filter. By repose the liquor furnishes a crop of very pure crystals, which require only to be dried. The mother-waters are treated in the following manner. Saturate the excess of acid with chalk, filter, and concentrate to 25°. By cooling a second crop of crystals will be obtained; and, by proceeding in a similar manner, even a third crop. But these crystals are somewhat coloured, and must be purified by recrystallization.

In relation to the above process, it may be observed that the proportion of oxychloride and cream of tartar must be adjusted according to the numbers given, on the assumption that the former is dry; but it by no means follows that the whole of the oxide should be dried. To proceed thus would be a waste of time. The mode of proceeding is to weigh the whole of the moist oxide, and afterwards to weigh a small part of it, and ascertain how much this loses in drying. Then, by a calculation, it is easy to determine how much the whole of the moist oxide would weigh in the dry state.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; and it is not material what plan is adopted, provided the crystals of the antimonial salt are carefully purified. In an extensive manufactory in London, antimony ash (see *page* 130) is employed for boiling with the cream of tartar, and it is stated to form the cheapest material for making tartar emetic. (*Pereira's Mat. Med.*) Mohr prefers the use of a *moist* oxide, prepared by adding gradually an intimate mixture of one part, each, of tersulphuret of antimony and nitrate of potassa, to a boiling mixture of one part of sulphuric acid and two of water. The liquid is boiled down nearly to dryness and allowed to cool. The grayish-white mass, thus formed, is then washed thoroughly with water. The details of this process are given by Soubeiran, by whom it is praised, in the *Journ. de Pharm.*, 3e sér., iii. 327.

Properties, &c. Tartrate of antimony and potassa was discovered in 1631 by Adrian de Mynsicht. It is in the form of transparent, colourless crystals, which possess a nauseous, metallic, styptic taste, and have usually the form of rhombic octohedrons. When prepared from the oxychloride it crystallizes in tetrahedrons. As it occurs in the shops, it is in the form of a white powder, resulting from the pulverization of the crystals. The crystals, when exposed to the air, effloresce slightly, and become white and opaque. They are insoluble in alcohol, but dissolve in proof spirit or wine.* (See *Vinum Antimonii*.) They are soluble in about 15 parts of water at 60° (in 20 parts, U. S., 21·8, Br.), and between 2 and 3 parts of boiling water. The late Dr. Perceval, of Dublin, alleged that good tartar emetic dissolves in twelve parts of water, and this statement agrees nearly with the results of Brandes, who found it to be soluble in 12·65 parts of water at 70°. Its aqueous solution slightly reddens litmus, and undergoes decomposition by keeping. If one-fifth of its bulk of alcohol be added to the water, the decomposition is prevented. It is incompatible with acids, alkalies and their carbonates, some of the earths and metals, chloride of calcium, and acetate and subacetate of lead. It is incompatible also with astringent infusions and decoctions, as of rhubarb, cinchona, catechu, galls, &c.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent.

Characteristics and Tests of Purity. Tartar emetic, when pure, exhibits its appropriate crystalline form. A crystal or two, dropped into a solution of hydrosulphuric acid, will be covered with an orange-coloured deposit of tersulphuret of antimony; and hydrosulphuric acid gas causes an orange-red pre-

* Alcohol precipitates it from its aqueous solution, and Mr. T. S. Wiegand proposes as a convenient method of obtaining it in fine powder, to boil an ounce of it in four times its weight of water, and to pour the solution into a pint and a half of 95 per cent. alcohol. (*Am. Journ. of Pharm.*, Sept. 1858, p. 407.)

cipitate with its solution. One hundred grains of the salt, dissolved in water, yield forty-nine grains of tersulphuret with this test. (*Lond. Pharm.*, 1851.) "Twenty grains dissolve without residue in an [Imperial] fluidounce of distilled water [437·5 grains] at 60°; and the solution gives with sulphuretted hydrogen an orange precipitate, which, when washed and dried at 212°, weighs 9·91 grains." (*Br.*) Entire solubility in water is not a character belonging exclusively to the pure salt, for, according to the late Mr. Hennell, tartar emetic may contain 10 per cent. of uncombined cream of tartar, and yet be wholly soluble in the proper proportion of water. (*Phillips.*) This being the case, the character, given in the U. S. and Br. Pharmacopœias, of entire solubility in 20 or 21 8 parts of water, is not to be depended upon. A dilute solution is not precipitated by chloride of barium or nitrate of silver, nor rendered blue by ferrocyanide of potassium. A solution, containing one part of the salt in forty of water, is not disturbed by an equal volume of a solution of eight parts of acetate of lead in thirty-two of water and fifteen of acetic acid. This test is adopted in the U. S. Pharmacopœia from the Edinburgh, and is intended to show the absence of uncombined bitartrate of potassa; for, when the acidulated acetate is used as here directed, it does not form the white tartrate of lead with the pure antimonial salt, but only with the bitartrate, when this happens to be present. The acidulated acetate is said to be capable of detecting 1 per cent. of this impurity in tartar emetic; but Dr. Christison finds difficulties in using this test which render it too precarious for practice. Mr. Hennell's method of detecting uncombined bitartrate, is to add a few drops of a solution of carbonate of soda to a boiling solution of the antimonial salt. If the precipitate formed is not redissolved, no bitartrate is present.

The impurities found in tartar emetic are uncombined cream of tartar from faulty preparation or fraudulent admixture, tartrate of lime, iron, sulphates, and chlorides. The mode of detecting cream of tartar has been indicated above. Tartrate of lime is derived from the cream of tartar, which always contains this impurity. It is apt to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Iron is sometimes present, especially when the antimonial salt has been prepared from glass of antimony. It is detected by a blue colour being *immediately* produced by ferrocyanide of potassium, added after a little acetic acid. If the blue colour be *slowly* produced, it may arise from reactions on the iron of the ferrocyanide itself. If much iron be present, the solution of the tartar emetic will be yellow instead of colourless. Sulphates are detected by chloride of barium. The presence of a chloride is shown by a precipitate being produced by nitrate of silver, added to a dilute solution. According to Serullas, tartar emetic, except when well crystallized, and all the other antimonial preparations usually contain a minute proportion of arsenic, derived from the native tersulphuret of antimony, which almost always contains this dangerous metal. For the mode of detecting it, see *Acidum Arseniosum.* Tartar emetic should always be bought by the apothecary in good crystals, in which state the salt is pure, or very nearly so, and entirely free from arsenic. Its powder is perfectly white; and, when it is yellowish-white, iron is probably present. It is said that some druggists ignorantly prefer a tartar emetic which is yellowish-white in powder.

It has been already stated, in general terms, that tartar emetic in solution is incompatible with acids and alkalies, and with some of the earths; but this salt is so important, that some details in regard to the effects of particular reagents, included under these titles, seem to be necessary. Muriatic and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of terchloride or subsulphate of antimony, mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of it. When caustic potassa is added to a tolerably concentrated solution, it produces at first no effect, then a precipitate of teroxide, and afterwards the solution of this precipitate, if the addition of the alkali be continued. Lime-water acts in a weaker solution, and throws down a white precipitate, consisting of the mixed tartrates of lime and antimony. Car-

bonate of potassa affects still weaker solutions, throwing down a white precipitate of teroxide; but this test does not act in solutions containing less than a quarter of a grain to the fluidounce. Ammonia, both pure and carbonated, precipitates a solution of tartar emetic, throwing down the pure teroxide. To these reagents may be added infusion of galls, which, when fresh and strong, causes a dirty, yellowish-white precipitate of tannate of teroxide of antimony

Composition. Tartar emetic consists of two eqs. of tartaric acid 132, one of potassa 47·2, one of teroxide of antimony 153, and two of water 18 = 350·2. It is evident that it contains tartaric acid and potassa in the proportion to form bitartrate of potassa or cream of tartar; and, accordingly, it may be viewed as a compound of one eq. of cream of tartar, and one of antimonial teroxide. The excess of acid in the bitartrate may be considered as united with the teroxide; and on that view it is a double salt, composed of tartrate of potassa, with tartrate of teroxide of antimony. The U. S. name assumes it to be a double salt. According to the view of the bibasic character of tartaric acid, which now begins to prevail, tartar emetic consists of one eq., each, of teroxide of antimony, potassa and tartaric acid, with two eqs. of water ($SbO_3,KO,C_8H_4O_{10}+2HO$); the equivalent number of the acid being doubled.

Medical Properties and Uses. Tartrate of antimony and potassa is the most important of the antimonials, and is capable of fulfilling numerous indications in disease. Its general action is that of a sedative to the circulation; while, on the contrary, it excites most of the secretions. According to the dose, and the peculiar circumstances under which it is administered, it acts variously as an alterative, diaphoretic, diuretic, expectorant, purgative, and emetic. In *minute* doses it is employed with a view to its alterative effects, and has been found useful in diseases of the skin. In such doses it has been given with alleged benefit in various chronic pulmonary affections, but especially in phthisis. In phthisical cases it was prescribed in this way, in 1818, by Lanthois, of Montpellier, and sometimes with advantage; and afterwards with encouraging results, by others. In the beginning of phthisis, the remedy, in these minute doses, may have exercised a meliorating effect by its influence on the bronchial inflammation which so constantly attends this disease. In *small* doses, mostly associated with saline remedies, such as nitre or sulphate of magnesia, and assisted by copious dilution, it is frequently resorted to in febrile complaints, for the purpose of producing perspiration, which is often freely induced, especially if the remedy gives rise to nausea. If the surface be exposed to cool air, so as to constrict the pores, the tendency will be to the kidneys, with the effect of producing an increased flow of urine. It also proves useful, on many occasions, in pulmonary and bronchial disease as an expectorant; and with a view to its action in this way, it is conjoined with squill, ammoniac, and similar remedies. In *full* doses it acts as an emetic, and is characterized by certainty, strength, and permanency of operation. It remains longer in the stomach than ipecacuanha, produces more frequent and longer-continued efforts to vomit, and exerts a more powerful impression on the system. The nausea and attendant prostration are often very considerable. As an emetic its use is indicated where the object is not merely to evacuate the stomach, but to agitate and compress the liver and other abdominal viscera. By the extension of its action to the duodenum, it often causes copious discharges of bile, and may thus prove useful when there is a morbid excess of that secretion. It is employed as an emetic in jaundice, hooping-cough, and croup, and in several diseases of the nervous system, such as mania, amaurosis, tic douloureux, &c. In efforts to reduce old dislocations, its relaxing power over the muscles when it nauseates, has been taken advantage of, to facilitate the operation. Tartar emetic often incidentally produces purging. In reference to this tendency, practitioners are in the habit of adding it to purgatives, the operation of which it promotes in a remarkable degree. It is contraindicated in diseases of great debility, in the advanced stages of febrile affections, and in fevers with irritability of stomach.

Of late years, on the continent of Europe, and to some extent in Great Britain and this country, tartar emetic has been given in *large* doses, with a view to its

sedative, or, as it is usually termed, *contrastimulant* operation. This practice originated with Rasori, professor of clinical medicine at Milan, who published his views in 1800. The principal diseases in which it has been thus used are pneumonia, pleurisy, bronchitis, acute rheumatism, especially of the joints, articular dropsies, chorea, hydrocephalus, and apoplexy. The medicine is directed in doses, varying from a grain to two grains or more, every two hours, dissolved in a small quantity of water; the patient being restricted in the use of drinks whilst under its operation. It is stated that, when the remedy is thus given in diseases of high action, it seldom produces vomiting, an effect which the author of the practice wished to avoid. The power of the system to bear large doses of tartar emetic, during the existence of acute diseases, was considered by Rasori to depend upon the coexisting morbid excitement, and the capability of bearing them was expressed by the term *tolerance*. It is in pneumonia especially that the contrastimulant practice has most advocates. It is admitted to have the effect of lowering the force and frequency of the pulse, and the rapidity of the respirations; and, in not a few instances, produces marked remedial effects. In pleurisy and bronchitis, the advantages of the same practice are less decided. Though we are disposed to admit the controlling influence of tartar emetic, when thus exhibited, in the diseases named; yet we by no means think that its use should supersede blood-letting, or even form our chief reliance. In cases, however, in which blood-letting, both general and local, has no effect, or has been carried as far as the circumstances of the case will warrant, tartar emetic, administered on the contrastimulant plan, may be found useful. In croup the remedy proves efficacious not merely by the free vomiting which it produces, but, if given in large doses, on the contrastimulant principle. If the tolerance cannot be otherwise established, laudanum may be conjoined with the antimonial, in order to bring it about. In the treatment of articular dropsies, the decided benefit derived from large doses of tartar emetic is fully shown by M. Gimelle, who has reported twenty-eight successful cases. The medicine was gradually increased from four grains to sixteen or twenty daily, and, generally, the tolerance was established on the first day. The effusion was absorbed in a space of time varying from eight to sixteen days. Tartar emetic has been used with success in delirium tremens; the antimonial being sometimes given alone, at other times conjoined with opium or laudanum. This practice originated with the late Dr. Joseph Klapp, of this city. Dr. Lange, of Königsberg, recommends tartar emetic in cases of uræmia, particularly when it supervenes on the exanthemata, giving it in solution in the dose of about a quarter of a grain every quarter or half hour. (*Ann. de Thérap.*, 1866, p. 115.) Dr. Parker has employed it with much advantage for the promotion of uterine contraction, in protracted delivery dependent on inertia of the uterus. It relaxes the os uteri and perinæum, increases the mucous secretion of the vagina, and augments the contractile force of the longitudinal and transverse fibres. He gives it in small doses every ten or fifteen minutes till nausea supervenes. (*Ibid.*, 1865, p. 184.)

Tartar emetic, in the form of enema, has been used with great benefit, in rigidity of the os uteri, by Dr. James Young, and by Dr. H. R. Storer, of Boston. The formula employed by Dr. Young was one grain of the antimonial salt to six fluidounces of warm water.

Externally, tartar emetic is often employed as a counter-irritant, mixed with lard, or cerate, or in the form of a plaster. (See *Unguentum Antimonii* and *Emplastrum Antimonii.*) It causes, after a longer or shorter interval, a burning sensation, accompanied by a peculiar and painful pustular eruption. This mode of producing counter-irritation is serviceable in a number of diseases; but particularly in deep-seated pains, spinal irritation, hooping-cough, and chronic inflammation of the chest threatening consumption. Care must be taken, when the salt is applied by means of a plaster, that the pustular inflammation does not proceed too far; as, in that event, it produces deep and very painful ulcerations, difficult to heal. According to M. Guérin, inflamed parts exhibit a con-

dition of tolerance to the local effects of tartar emetic, evinced by the absence of pustulation. In support of this view, he asserts that he has treated hundreds of cases of acute arthralgia with tartar emetic ointment with the best effects, mostly without the production of any eruption; and when the pustules were produced, the benefit accrued before they appeared. When no pustulation follows, M. Guérin supposes that the antimony acts by absorption.

Tartar emetic is generally given in solution, and in an amount which varies with the object in view in its administration. Its dose as an alterative is from the thirty-second to the sixteenth of a grain; as a diaphoretic or expectorant, from the twelfth to the sixth of a grain; and as a nauseating sudorific, from a quarter to half a grain; repeated, according to circumstances, every hour, two, or four hours. With a view to its alterative effect, a pint of water, containing from one-quarter to half a grain, may be taken daily as drink. If required to act as a purgative, a grain may be dissolved in half a pint of water with an ounce of Epsom salt, and two tablespoonfuls of the solution given every two or three hours. As an emetic the full dose is from two to three grains; though it is usually given in the dose of a grain, dissolved in a tablespoonful of water, repeated every ten or fifteen minutes till it vomits; the operation being aided by warm water or chamomile tea. It is often conjoined with ipecacuanha, in the proportion of one or two grains to twenty of that emetic. For convenient administration in small doses, the Pharmacopœias direct it dissolved in wine. It is given very conveniently to children in dilute aqueous solution, which, being nearly tasteless, is readily taken by them. In all cases it should be used with caution; as it sometimes acts even in small doses with unexpected violence.

Effects as a Poison. The symptoms of acute poisoning by tartar emetic are an austere metallic taste; nausea; copious vomiting; frequent hiccough; burning pain in the stomach; colic; frequent stools and tenesmus; fainting; small, contracted, and accelerated pulse; coldness of the skin; sometimes intense heat; difficult respiration; loss of sense; convulsive movements; very painful cramps in the legs; prostration, and death. Ten grains is the smallest dose reported to have proved fatal. To the above effects is sometimes added difficulty of deglutition. Occasionally vomiting and purging do not take place; and, when they are absent, the other symptoms are aggravated. Sometimes a pustular eruption is produced, like that caused by the external application of the antimonial; as in a case reported by Dr. J. T. Gleaves, of Tennessee. These are the effects, observed in different cases, on the healthy economy; but doses which, taken in health, would prove fatal, are sometimes borne with safety in certain morbid states of the system, attended with acute inflammation.

The effects of slow poisoning by tartar emetic on inferior animals have been carefully studied by Dr. B. W. Richardson, of London, and Dr. Nevins, of Liverpool. All the surfaces absorb the solution of the salt, and the metal is found in all the tissues after death, except that of the brain; but most abundantly in that of the liver. The elimination of the poison is effected by all the secreting organs, but especially by the kidneys. The tolerance of antimony is attributed by Dr. Richardson to the eliminating action of these glands. The pathological appearances are general congestion, marked fluidity of the blood, and intense vascularity of the stomach and sometimes of the rectum, but without ulceration. No other pulmonary lesion occurs but simple congestion. (See *Am. Journ. of Med. Sci.*, Jan. 1857, p. 266.) The general results obtained by Dr. Richardson are confirmed by the experiments of Dr. Nevins. (*Pharm. Journ.*, Feb. 1857, p. 415.)

In treating a case of poisoning by tartar emetic, if it is found that the patient has not vomited, immediate recourse must be had to tickling the throat with a feather, and the use of abundance of warm water. Usually, however, the vomiting is excessive and distressing; and here it is necessary to use remedies calculated to decompose the poison, and to allay the pain and irritation. To effect the former object, astringent decoctions and infusions, such as of Peruvian bark and common tea, are recommended as antidotes. These, however, act but imperfectly, according to M. Toulmouche, who found that a decoction of cinchona

had usually no power in lessening the emetic effect of this antimonial. Similar observations had been made by Dr. Clutterbuck. (*Pereira.*) The decoction of galls acts more decidedly; but M. Toulmouche accords the preference to the galls in substance. A case of poisoning with half an ounce of tartar emetic, successfully treated with copious draughts of green tea and large doses of tannin, is reported by Dr. S. A. McCreery, of the U. S. Navy (*Am. Journ. of Med. Sci.*, Jan. 1853, p. 131.) Galls no doubt act by their tannin, which forms, with the antimonial part of the salt, the insoluble and probably inert tannate of antimony. To stop the vomiting and relieve pain, laudanum should be given, either by the mouth or by injection, and to combat consecutive inflammation, leeches to the epigastrium and other antiphlogistic measures may be resorted to.

After death from suspected poisoning by tartar emetic, it is necessary to search for the poison in the body. The contents of the stomach should be digested in water, acidulated with muriatic and tartaric acids. The former acid will serve to coagulate organic matter; the latter to give complete solubility to the antimony. The solution obtained, after having been filtered, should be subjected to a stream of sulphuretted hydrogen, which, if tartar emetic be present, will throw down the orange-red tersulphuret of antimony, distinguished from tersulphuret of arsenic and all other precipitates by forming with hot muriatic acid a solution, from which, when added to water, a white curdy precipitate of oxychloride of antimony (powder of Algaroth) is thrown down. Sulphuretted hydrogen is by far the most delicate test for tartar emetic.

Sometimes the antimony cannot be found in the stomach and bowels, and yet may exist in other parts. When it leaves the alimentary canal, it has been found by Orfila especially in the liver and kidneys, and their secretions. The mode of extracting the antimony, recommended by Orfila, is to carbonize the dried viscera with pure concentrated nitric acid in a porcelain capsule, to boil the charred mass obtained for half an hour with muriatic acid, assisted with a little nitric acid, to filter the liquor, and introduce it into Marsh's apparatus. Antimoniuretted hydrogen will be formed, which, being inflamed, will deposit the antimony on a cold surface of porcelain as a black stain, distinguishable from the similar stain produced by arsenic by its less volatility, and by its forming, with hot muriatic acid, a solution which affords a white precipitate of oxychloride of antimony when added to water.

Reinsch's process is a good one for separating antimony from the tissues, and was first used for that purpose by Dr. Alfred Taylor, of London. The tissues are boiled in muriatic acid, and a bright slip of copper is immersed in the hot solution. The metallic film, deposited on the copper, must be proved to be antimony. This is done by Dr. Odling by first boiling the coated copper in a solution of permanganate of potassa, with a little excess of potassa, for a few minutes, whereby the antimony becomes oxidized and dissolved, and then passing sulphuretted hydrogen through the filtered and acidulated solution. The characteristic orange-red precipitate of tersulphuret of antimony is produced, which may be tested for antimony as above mentioned. Mr. H. H. Watson has simplified Dr. Odling's process by dispensing with the use of the permanganate of potassa. He subjects the coated copper slip, in a tube, to a boiling very dilute solution of caustic potassa, the metal being alternately drawn out of and immersed in the solution, by the aid of a copper wire, until the whole of the coating is oxidized and dissolved. The solution is then treated as directed by Dr. Odling. (*Med. Times and Gaz.*, July, 1857, page 613.)

ANTIMONII OXIDUM. *U. S.*, *Br.* *Oxide of Antimony.*

"Take of Sulphuret of Antimony, in very fine powder, *four troyounces*; Muriatic Acid *eighteen troyounces*; Nitric Acid *a troyounce and one hundred and twenty grains*; Water of Ammonia *a fluidounce and a half*; Water, Distilled Water, each, *a sufficient quantity*. Introduce the Sulphuret into a flask,

of the capacity of two pints, and, having added the Muriatic Acid, digest, by means of a sand-bath, until effervescence ceases. Then, having removed the flask from the sand-bath, add the Nitric Acid gradually; and, when nitrous acid vapours cease to be given off, and the liquid has grown cold, add to it half a pint of Water, and filter. Pour the filtered liquid gradually into twelve pints of Water, constantly stirring, and allow the precipitate to subside. Decant the supernatant liquid, and wash the precipitate twice by decantation, using, each time, eight pints of Water. Then transfer it to a muslin filter to drain, and, after the draining is completed, wash it with Water until the washings cease to have an acid reaction. Next introduce it into a suitable vessel, and subject it to the action of the Water of Ammonia for two hours; at the end of which time, transfer it to a moistened muslin filter, and wash it with Distilled Water as long as the washings produce a precipitate with nitrate of silver. Lastly, dry the precipitate upon bibulous paper with the aid of a gentle heat." *U. S.*

"Take of Solution of Chloride of Antimony *sixteen fluidounces;* Carbonate of Soda *six ounces* [avoirdupois]; Water *two gallons* [Imperial measure]; Distilled Water *a sufficiency.* Pour the Antimonial Solution into the Water, mix thoroughly, let the precipitate settle, remove the supernatant liquid by a siphon, add one gallon [Imp. meas.] of Distilled Water, agitate well, let the precipitate subside, again withdraw the fluid, and repeat the process of affusion of Distilled Water, agitation, and subsidence. Add now the Carbonate of Soda previously dissolved in two pints [Imp. meas.] of Distilled Water, leave them in contact for half an hour, stirring frequently, collect the deposit on a calico filter, and wash with boiling distilled water until the washings cease to give a precipitate with a solution of nitrate of silver acidulated by nitric acid. Lastly, dry the product at a heat not exceeding 212°." *Br.*

In the U. S. formula the solution of terchloride is prepared as the first step of the proceedings; in the British is taken already formed, as the result of a distinct process. When tersulphuret of antimony is digested with muriatic acid, an interchange of principles takes place; the hydrogen of the acid uniting with the sulphur of the antimonial, and escaping as sulphuretted hydrogen, while the chlorine and antimony combine to form terchloride of antimony which is held in solution. The effect of the nitric acid is supposed to be to render the oxide whiter, by decomposing any remaining sulphuretted hydrogen, and thus preventing it from contaminating the product. Though the result thus far is an aqueous solution of the terchloride, this cannot be diluted beyond a certain degree without decomposition. Hence, if largely diluted, as when poured into an excess of water, decomposition takes place, and a white powder is precipitated, formerly called *powder of Algaroth* (see *Part* III.), which is an oxychloride, having usually the formula $2SbO_3,SbCl_3+HO$. The terchloride is in part decomposed by the water, the elements of which convert it into muriatic acid and teroxide. The muriatic acid remains in solution, while two eqs. of teroxide fall in union with one eq. of terchloride, forming the oxychloride of the above formula. The composition of the powder, however, is not uniform; as it contains more teroxide, the greater the proportion of water used in the decomposition. (E. Baudrimont, *Journ. de Pharm.*, Juin, 1856, p. 438.) The oxychloride is first washed with abundance of water to separate adhering muriatic acid, and then acted upon by a solution of alkali (ammonia, *U. S.*, carbonate of soda, *Br.*) to decompose the terchloride, with the effect of adding to the amount of teroxide; after which the teroxide only requires to be washed with water in order to render it pure. The last washing separates the muriate of ammonia or chloride of sodium, resulting from the decomposition of the terchloride; and the water of this washing is tested, in both formulas, by nitrate of silver, until the presence of a chloride ceases to be indicated.

Properties. Teroxide of antimony is a heavy, grayish-white powder, permanent in the air, insoluble in water, but readily soluble in muriatic or tartaric acid, or in a boiling solution of bitartrate of potassa. Heated in close vessels it becomes yellow, fuses at a full red heat, and finally sublimes in crystalline

needles. When cooled from a state of fusion it forms a fibrous crystalline mass. Heated in open vessels it suddenly becomes red hot, and, by the absorption of oxygen, changes into antimonious acid, which differs from the teroxide in being insoluble in muriatic acid, less fusible, and not volatile. This oxide is the active ingredient of all the medicinal preparations of antimony. It is frequently impure from the presence of antimonious acid, in which case it is not *entirely* soluble in muriatic acid. If it contain terchloride, which it is apt to do from the imperfect action of the alkaline solutions employed in its purification, its solution in tartaric acid will be precipitated by nitrate of silver. When antimonious acid is substituted for it, the fraud may be detected by the spurious preparation being entirely insoluble in muriatic acid. Teroxide of antimony consists of one eq. of antimony 129, and three of oxygen 24=153.

Medical Properties. This oxide, which must not be confounded with the powder of Algaroth, has the general therapeutic properties of the antimonials. It deserves more attention than has been paid to it; and its effects, comparatively with those of tartar emetic, should be carefully studied. It is probable that its sedative operation would be found to be the same, with less nausea and disturbance of the stomach. Like antimonial powder, it is unequal in its effects, sometimes vomiting, at other times being apparently inert. This inequality of action is plausibly explained by the state of the stomach as to acidity, the presence of acids giving the medicine activity; and this explanation is confirmed by the experiments of Dr. Osburn, of Dublin, with the Dublin oxide. As to the French Codex oxide, prepared by boiling the oxychloride with a solution of bicarbonate of potassa, the inequality is attributed by M. Durand, of Caen, to the presence of more or less terchloride, which is separated with difficulty. Objecting to the Codex oxide, M. Durand proposes to prepare the teroxide by precipitating tartar emetic with ammonia in excess. Thus obtained it contains no terchloride, and does not vomit. (*Journ. de Pharm.*, 3e sér., ii. 364.) The dose of teroxide of antimony is three grains, every two or three hours, given in powder with syrup or molasses, or in pill made with confection of roses or other suitable excipient. It was introduced into the existing edition of the U. S. Pharmacopœia, to be used in the preparation of tartar emetic.

ANTIMONII OXYSULPHURETUM. *U.S.* *Oxysulphuret of Antimony. Kermes Mineral.*

"Take of Sulphuret of Antimony, in very fine powder, *a troyounce;* Carbonate of Soda *twenty-three troyounces;* Water *sixteen pints.* Dissolve the Carbonate of Soda in the Water previously heated to the boiling point, and, having added the Sulphuret of Antimony, boil for an hour. Then filter rapidly into a warm earthen vessel, cover this closely, and allow the liquid to cool slowly. At the end of twenty-four hours, decant the supernatant liquid, drain the precipitate on a filter, wash it with boiled water previously allowed to become cold, and dry it without heat. Lastly, preserve the powder in a well-stopped bottle, protected from the light." *U. S.*

Though very long in use as a medicine, and much employed on the Continent of Europe, it was only at the late revision that this preparation was admitted into the U. S. Pharmacopœia, having been superseded by the precipitated sulphuret, which was supposed to have very similar if not identical properties.

Kermes mineral, according to Thenard, may be obtained by treating the tersulphuret of antimony in three ways; 1st with a boiling solution of the carbonated alkalies, 2d with a boiling solution of the caustic alkalies, and 3d with the carbonated alkalies at a red heat. These several processes give brown powders, which vary in their shade of colour, and which, though usually considered as identical, differ in composition. The kermes obtained by means of the carbonated alkalies in solution is an oxysulphuret, that is, a compound of hydrated tersulphuret of antimony with the teroxide; while the product, when either the

caustic alkalies in solution, or the carbonated alkalies at a red heat are used, is essentially a hydrated tersulphuret, though containing occasionally a little oxysulphuret. It is the first of these methods that has been adopted in the U. S. process. It is in fact the formula of Cluzel, as published in former editions of the U. S. Dispensatory (see 11th ed. p. 926), and is substantially the same with that given in the French Codex of 1837.

The rationale of the formation of kermes by this process is as follows. A portion of the carbonate of soda is converted, by a transfer of carbonic acid, into caustic soda and sesquicarbonate. By a double decomposition taking place between a part of the tersulphuret of antimony and the caustic soda, sulphuret of sodium and teroxide of antimony are formed. The undecomposed portion of the tersulphuret then dissolves in the solution of sulphuret of sodium, and the teroxide in that of the remaining carbonate of soda. The tersulphuret and teroxide, being both more soluble in these menstrua hot than cold, precipitate together as the liquid cools, and constitute this variety of kermes. Thus obtained it is light, velvety, of a dark reddish-purple colour, brilliant in the sun, and of a crystalline appearance. It consists, according to M. Henry, jun., of tersulphuret of antimony 62·5, teroxide 27·4, water 10, and soda a trace; proportions which correspond most nearly with two eqs. of tersulphuret, one of teroxide, and six of water. From the presence of so large a proportion of teroxide of antimony in this variety of kermes, it must be far more active than the other kinds, and ought, therefore, to be preferred for medical use.

Kermes, when obtained by means of the caustic alkalies, may be formed by the use of either potassa or soda. When the former alkali is selected, it may be prepared by boiling, for a quarter of an hour, two parts of the tersulphuret of antimony with one part of caustic potassa dissolved in twenty-five or thirty parts of water, filtering the liquor, and allowing it to cool; whereupon the kermes precipitates. In this process one portion of the tersulphuret, by reacting with a part of the potassa, gives rise to teroxide of antimony and sulphuret of potassium. A second portion dissolves in the solution of sulphuret of potassium formed, and a third forms an insoluble compound with a part of the teroxide. The remainder of the teroxide unites with the undecomposed potassa, forming a compound, which, being but sparingly soluble, is only in part dissolved. The hot filtered liquor, therefore, contains this compound dissolved in water, and tersulphuret of antimony dissolved in the solution of sulphuret of potassium. By refrigeration, the tersulphuret in a hydrated state falls down, free or nearly free from teroxide, this latter being still held in solution by means of the caustic alkali.

Kermes may be obtained by the third method, that is, in the dry way, by the use of the carbonated alkalies at a red heat. If carbonate of potassa is selected, the process is as follows. Rub together two parts of tersulphuret of antimony and one of carbonate of potassa, fuse the mixture in a crucible by a red heat, reduce the fused mass to powder, boil it with water, and strain. As the strained liquor cools the kermes is deposited. The rationale of its formation is nearly the same with that of the formation of the second variety of kermes. An inferior kermes, prepared in the dry way, and intended for use in veterinary medicine, is directed in the French Codex of 1837 to be prepared by fusing together, well mixed, 500 parts of tersulphuret of antimony, 1000 of carbonate of potassa, and 30 of washed sulphur, reducing the fused mass to powder, and boiling it with 10,000 parts of water. The liquor, upon cooling, lets fall the kermes, which must be washed with care and dried.

The officinal oxysulphuret is an insipid, inodorous powder, of a purplish-brown colour, and soft and velvety to the touch. By the action of air and light it gradually becomes lighter coloured, and at last yellowish-white. It is readily and wholly dissolved by muriatic acid, with escape of hydrosulphuric acid gas, and is partly soluble in a hot solution of potassa, leaving a residue soluble in tartaric acid. It is sometimes adulterated with sesquioxide of iron. In Paris, in 1849, a number of the shops contained a spurious kermes of very handsome appearance, which was little else than this oxide. Kermes mineral first came into use

as a remedy in France about the beginning of the last century. Its mode of preparation was possessed as a secret by a French surgeon named La Ligerie. In 1720, the recipe was purchased by the French government and made public. Its remedial properties will be considered under the following head. B.

ANTIMONIUM SULPHURATUM. *U.S.*, *Br.* ANTIMONII SULPHURETUM PRÆCIPITATUM. *U.S.* 1850, *Dub.* ANTIMONII OXYSULPHURETUM. *Lond.* ANTIMONII SULPHURETUM AUREUM. *Ed.* *Sulphurated Antimony. Precipitated Sulphuret of Antimony.*

"Take of Sulphuret of Antimony, in very fine powder, *six troyounces;* Solution of Potassa *four pints;* Distilled Water, Diluted Sulphuric Acid, each, *a sufficient quantity.* Mix the Sulphuret of Antimony with the Solution of Potassa and twelve pints of Distilled Water, and boil the mixture over a gentle fire for two hours, constantly stirring, and occasionally adding Distilled Water so as to preserve the same measure. Strain the liquid immediately through a double muslin strainer, and drop into it, while yet hot, Diluted Sulphuric Acid so long as it produces a precipitate. Then wash the precipitate with hot water to remove the sulphate of potassa, dry it, and rub it into a fine powder." *U. S.*

"Take of Black Antimony *ten ounces* [avoirdupois]; Solution of Soda *four pints and a half* [Imperial measure]; Diluted Sulphuric Acid, Distilled Water, of each, *a sufficiency.* Mix the Black Antimony with the Solution of Soda, and boil for two hours with frequent stirring, adding Distilled Water occasionally to maintain the same volume. Strain the liquor through calico, and, before it cools, add to it by degrees the Diluted Sulphuric Acid till the latter is in slight excess. Collect the precipitate on a calico filter, wash with Distilled Water till the washings no longer precipitate with chloride of barium, and dry at a temperature not exceeding 212°." *Br.*

There are three forms of tersulphuret of antimony containing more or less teroxide; the *kermes mineral* already described; the *golden sulphur*, which is produced when, after the spontaneous subsidence of kermes mineral in the process for obtaining it, an acid is added to the liquid; and the *precipitated sulphuret*, which is made by precipitating the liquid before it has begun to deposit the kermes, and may be considered as consisting of the other two combined in one.

Golden sulphur (*sulphur auratum antimonii*) is prepared, according to the French Codex of 1837, by precipitating the solution remaining after the deposition of the kermes, in the formula in which one of the caustic alkalies is employed in the first stage of the process, as in the above formula, instead of a carbonate as in the one preceding it. The liquor, when caustic potassa has been used, consists *at first* chiefly of tersulphuret of antimony, dissolved in solution of sulphuret of potassium, but in part also of teroxide, dissolved in solution of potassa. By the action of the oxygen of the air on the liquor, however, the sulphuret of potassium has part of its potassium gradually converted into potassa, and thus passes to a higher state of sulphuration; and, consequently, the addition of an acid, while it throws down the tersulphuret and teroxide of antimony with disengagement of sulphuretted hydrogen, will separate at the same time the excess of sulphur which the sulphuret of potassium has gained. This excess of sulphur, combining with a portion of the tersulphuret of antimony, produces the pentasulphuret of that metal (*Gmelin*); and the resulting golden sulphur is a mixture of tersulphuret and teroxide of antimony, with more or less of the pentasulphuret. It is in the form of a powder of a golden-yellow colour. As it is partially decomposed by light, it should be kept in opaque vessels. It may be worth while to mention that the so-called *kermes liquor*, left after the use of the carbonated alkalies in solution, gives but little golden sulphur; while the liquors resulting from the two other processes yield it in abundance.

From the explanations above given, the reader is prepared to understand that the method of preparing sulphurated antimony of the U. S. and Br. Pharmacopœias, combines the process for forming kermes mineral by means of a *caustic alkali*, with that for obtaining golden sulphur; for, while the refrigeration of

the solution acting alone would cause the precipitation of the variety of kermes which contains little or no antimonial oxide, the sulphuric acid added would throw down more or less of the golden sulphur. But the question here arises, how far this golden sulphur would be identical with that obtained from the kermes liquor which has been kept for some time. From the explanations above given in relation to golden sulphur, it may be inferred as probable that the precipitate by acids, if thrown down immediately, while the solution is hot, as directed by the Pharmacopœias, and before the air has had time to act, would consist exclusively of tersulphuret and teroxide; but, if thrown down from kermes liquor which had been kept, would contain more or less of the pentasulphuret, according to the length of time which had elapsed. If these views be admitted, it follows that the so-called golden sulphur must be variable as to the pentasulphuret it contains, according to the greater or less change which the kermes liquor may have undergone by time, before being used for furnishing the precipitate.

Formerly, all the Pharmacopœias noticed in this work used a solution of caustic potassa in preparing precipitated sulphuret of antimony; but at present the British Council, following the London College, employs a solution of caustic soda. The use of soda, however, does not alter the theory of the process.

Properties of the Precipitated Sulphuret of Antimony (*Sulphurated Antimony, U. S., Br.*). This substance is a reddish-brown insoluble powder, tasteless when pure, but having usually a slightly styptic taste. When treated with twelve times its weight of muriatic acid of the sp. gr. 1·16, with the aid of heat, it is nearly all dissolved, with effervescence of sulphuretted hydrogen. The residue burns with the characters of sulphur, and leaves a scanty ash. The solution obtained, when added to water, is decomposed, giving rise to a white powder of oxychloride of antimony (powder of Algaroth). The solution, filtered from the powder, yields an orange-red precipitate with bihydrosulphate of ammonia, proving the presence of a portion of antimony, not thrown down by the water. A dark-coloured precipitate, produced by this test, shows the presence of contaminating metals, probably lead and copper. Water in which this preparation has been boiled, should not yield a white precipitate with chloride of barium or oxalate of ammonia. The non-action of these tests shows the absence of sulphuric acid and lime. When pure, precipitated sulphuret of antimony is completely soluble in a hot solution of potassa; but, as it is found in the shops, a white matter is usually left undissolved. When boiled with a solution of cream of tartar, about 12 per cent. of teroxide is dissolved; but, according to H. Rose, this method of determining the proportion of the teroxide cannot be relied on. Exposed to heat it takes fire, and burns with a greenish-blue flame, giving off sulphurous acid; while the metal remains behind in the state of a grayish oxide.

The London precipitated sulphuret of antimony, as analyzed by Mr. Phillips, consisted, in the 100 parts, of tersulphuret 76·5, teroxide 12, and water 11·5; proportions corresponding nearly with five eqs. of tersulphuret, one of teroxide, and fifteen of water. It usually contained a portion of pentasulphuret, as shown by the action of muriatic acid, which, when heated with this antimonial, forms the terchloride with disengagement of sulphur. (*Gmelin's Handbook*, iv. 989.) Its active ingredient is the teroxide; and, in reference to its presence, the London College called the preparation *oxysulphuret of antimony*. The Edinburgh College named it incorrectly *golden sulphuret of antimony:* this name being properly applicable to the precipitate produced by the sole action of acids, and not to that obtained by the action of acids and refrigeration conjointly.

Sulphurated Antimony is described in the British Pharmacopœia as "an orange-red powder, readily dissolved by caustic soda, also by hydrochloric acid with the evolution of sulphuretted hydrogen and the separation of a little sulphur. Boiled in water with acid tartrate of potash, the resulting solution is precipitated orange-red with sulphuretted hydrogen. Sixty grains of this preparation, dissolved in hydrochloric acid and dropped into water, give a white precipitate, which, when washed and dried, weighs about 53 grains." *Br.*

Medical Properties. *Precipitated sulphuret of antimony* (*sulphurated antimony*) is alterative, diaphoretic, and emetic. It is, however, an uncertain medicine, as well from the want of uniformity in its composition, as from its liability to vary in its action with the state of the stomach. It is seldom given alone, but generally in combination with calomel and guaiac, in the form of Plummer's pill, as an alterative in secondary syphilis and cutaneous eruptions, or with henbane or hemlock in chronic rheumatism. (See *Pilulæ Antimonii Compositæ.*) During its use the patient should abstain from acidulous drinks. Its dose as an alterative is from one to two grains twice a day, in the form of pill; as an emetic, from five grains to a scruple.

Kermes mineral, when prepared by means of the carbonated alkalies in the moist way, as it contains between two and three times as much teroxide as the precipitated sulphuret, is a more active preparation, and must be used in a smaller dose. It is sometimes given in large doses as an antiphlogistic remedy in peripneumony and other inflammations of the chest. Prof. Meigs recommends it as an invaluable medicine in childbed fevers, to promote diaphoresis, and to reduce the force of the circulation.

Golden sulphur acts like kermes mineral, but is much weaker, and must be given in a larger dose.

AQUA.

Water.

AQUA DESTILLATA. *U. S.*, *Br.* *Distilled Water.*

"Take of Water *eighty pints.* Distil two pints, using a tin or glass condenser, and throw them away; then distil sixty-four pints, and keep them in glass bottles." *U. S.*

"Take of Water *ten gallons* [Imperial measure]. Distil from a copper still, connected with a block-tin worm; reject the first half gallon, and preserve the next eight gallons." *Br.*

No natural water is sufficiently pure for certain pharmaceutical purposes; and hence the necessity of the above processes for its distillation. It is best to reject the first portion which comes over, as this may contain carbonic acid and other volatile impurities; and the last portion of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The distillation is usually performed with the ordinary still and worm; but, to avoid any impurity from the worm or the receiver, the condenser is directed in the U. S. Pharmacopœia to be of tin or glass. In the British formula the worm is ordered to be of block-tin; and the same is undoubtedly contemplated in our officinal process; as the ordinary tin-coated sheet-iron, commonly called tin, would be wholly unfit for the purpose. Mr. Brande states that distilled water often derives from the still a foreign flavour, which it is difficult to avoid. He, therefore, recommends that a still and condenser be kept exclusively for distilling water; or, where this cannot be done, that steam be driven through the worm for half an hour, for the purpose of washing it out before it is used, the worm-tub having been previously emptied. Mr. Mackay, of Edinburgh, cautions against distilling water in a still with a leaden head or leaden worm, for fear of contaminating the water with lead. Even the use of pure tin, which is generally considered unexceptionable, does not give perfect security against impurity; as water distilled from metallic alembics, with the head and worm of this metal, has a peculiar odour which it retains for some time. A portion of distilled water thus prepared, after having been kept for four months in a well-stopped bottle, was found by M. Flech, an apothecary of Kevelaer, to have deposited white flocculi, which proved on examination to consist of oxidized tin; and the water, besides, contained tin in solution and a little ammonia. M. Flech supposes that a part of the water was decomposed; its oxygen uniting with the tin, and its hydrogen in the nascent state with

the nitrogen of the air to form ammonia; and he is disposed, moreover, to ascribe to this cause the peculiar odour referred to, which is never perceived when the distillation is performed in glass vessels. (*Journ. de Pharm.*, Fév. 1860, p. 125.)

Properties, &c. Distilled water, as usually obtained, has a vapid and disagreeable taste, and is not perfectly pure; water, to be rendered so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua*. Distilled water should undergo no change by sulphuretted hydrogen, or on the addition of tincture of soap, subacetate of lead, chloride of barium, oxalate of ammonia, nitrate of silver, or lime-water, and should evaporate without residue. It is uselessly employed in some formulas, but is essential in others. As a general rule, when small quantities of active medicines are to be given in solution, and in the preparation of collyria, distilled water should be directed. The following list contains the chief substances which require distilled water as a solvent: tartar emetic, corrosive sublimate, nitrate of silver, the chlorides of barium and calcium, acetate and subacetate of lead, permanganate of potassa, the sulphates of iron and zinc, sulphate of quinia, sulphate, muriate, and acetate of morphia, and, in general terms, all the alkaloids and their salts. Distilled water is used in preparing the officinal diluted acids for absorbing gaseous ammonia, and for forming nearly all the officinal aqueous solutions. B.

AQUÆ. *U. S.*

Medicated Waters.

Under this head are included, in the United States Pharmacopœia, all preparations, consisting of water holding volatile or gaseous substances in solution, many of which were formerly obtained by distillation, and some still continue to be so. They include the preparations formerly specially designated as "Distilled Waters," having been made by distilling water from plants or parts of plants containing volatile oil. Distilled water is now placed in the Pharmacopœia under the same head; but we have given it the distinct position which it held in the edition of 1850, and which it might very properly, we think, have continued to hold in the present.

The Distilled Waters, as thus defined, hold a much more prominent position in the pharmacy of Europe, particularly of continental Europe, than in that of the United States; and a great deal of thought and elaborate investigation have been bestowed upon the various conditions calculated to furnish the best products in the most convenient method. It would be doing injustice to the subject not to give it a distinct consideration in a work like the present, though its relative want of importance with us will render our remarks comparatively brief.

Many vegetables impart to water distilled from them their peculiar flavour, and more or less of their medical properties. The Distilled Waters chiefly used are those prepared from aromatic plants, the volatile oils of which rise with the aqueous vapour, and are condensed with it in the receiver. But, as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed chiefly as pleasant vehicles or corrigents of other medicines.

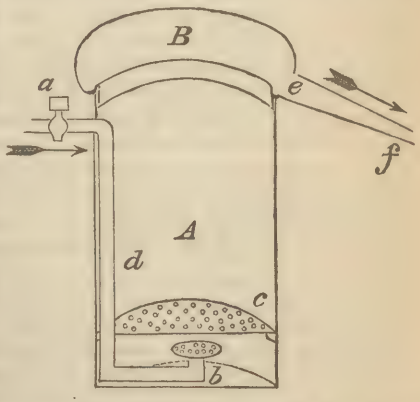
In the preparation of the Distilled Waters, dried plants are sometimes used, because the fresh are not to be had at all seasons; but the latter, at least in the instance of herbs and flowers, should be preferred if attainable. Flowers which lose their odour by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state afford Distilled Waters of delicate flavour. Indeed, some pharmaceutists prefer the salted flowers in certain instances, believing that the Waters distilled from them keep better than when prepared from the fresh flowers. Mr. C. R. Tichborne has discovered a new method of preserving flowers, which is said to answer even better than the use of salt. It consists simply in immersing the fresh flowers in glycerin, which preserves them with all their aromatic properties

wholly unimpaired. The flowers, as of the elder, rose, and orange, should be gathered after full expansion, and packed firmly in wide-mouthed bottles or jars, but without crushing them. The glycerin is then to be poured on until it covers them, and the vessel closed. Mr. Tichborne has kept flowers in this way for two years; and at the end of that time procured from them distilled waters, of which the perfume has equalled that of the waters prepared from recent flowers. It is not necessary that the glycerin should be perfectly pure; but it should be without smell. (*Pharm. Journ. and Trans.*, 2d ser., vii. 135.)

The idea at one time prevailed, to a considerable extent, that Waters kept better distilled from dried herbs than from fresh; and the opinion was true in regard to those prepared with the defective alembics of former times, and by a naked fire; but experiment has sufficiently established the fact, that, with a suitable apparatus, and a regulated heat, the fresh herbs yield products which, while they have a more agreeable odour of the plant, keep quite as well as those from dried herbs. (*Journ. de Pharm.*, Mai, 1861, p. 359.)

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previously to the operation. The quantity of materials should not bear too large a proportion to the capacity of the alembic, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state till the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the vegetable matter; lest a portion of the latter, coming in contact with the sides of the vessel, might be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously, or carried too far, a slimy matter is apt to form, which adheres to the sides of the alembic above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil-bath, regulated by a thermometer, or of a bath of solution of chloride of calcium, by which any temperature may be obtained between 212° and 270°, according to the strength of the solution; or, when the process is conducted upon a large scale, by means of steam introduced under pressure into a space around the still. A convenient mode of applying heat by steam, is by means of a coil of leaden tube placed in the bottom of the still, having one end connected with a boiler, and the other passing out beneath or at the side, and furnished with a stop-cock, by which the pressure may be increased, or the condensed water drawn off at will. If any volatile oil float upon the surface of the Distilled Water, it may be separated.*

From a series of experiments made in Paris in reference to the best mode of applying heat, it was concluded that, as regards the great majority of aromatics, the direct application of steam was preferable, because the Distilled Waters prepared by means of it have a freshness of aroma that is wanting in the others, are always free from the odour of the still, are much more limpid, are less apt to deposit mucilaginous matter, and keep better; but that exceptions to the general rule are afforded by bitter almonds, cherry-laurel leaves, mustard, and horseradish, in all of which the oil does not pre-exist in the plant, but is formed upon contact with water; by woods, barks, and roots, the tissue of which cannot be sufficiently penetrated by steam; and by roses. (*Journ. de Pharm.*, Mai, 1861, p. 364.) Later experiments have led to the conclusion that even these substances are most advantageously treated by distillation with steam; and that, in fact, there is no exception to the general rule. All inconvenience and danger in this process are



* This direction is generally given; but, in a communication to the Pharmaceutical Society of England, Mr. Haselden recommends the excess of oil to be well shaken with the water, and the whole to be transferred to the stock vessel, where it may be allowed to rest, and the oil to separate. He thinks the water keeps better when thus treated; and the full strength is always ensured. The stock vessel he prefers made of stoneware, and furnished with a tap placed two inches from the bottom, whereby the water may be drawn off clear when wanted for the ordinary shop bottles; the oil either rising to the top, or sinking to the bottom of the vessel, according to its specific gravity. (*Pharm. Journ.*, xvi. 14, 15.)—*Note to the eleventh edition*

avoided by care to have tubes of large diameter for the supply of the steam, which should be received into a free space reserved, at the bottom of the alembic, by means of a diaphragm pierced with holes. To prevent the loss of vapour, it is sufficient to lute the apparatus by strips of linen or muslin covered with glue or dextrin paste, making two or three turns around the alembic. (*Ibid.*, Juin, 1864, p. 520.)*

But, however carefully the process may be conducted, the Distilled Waters prepared from plants always have at first an unpleasant smoky odour. They may be freed from this by exposure for a short time to the air, before being enclosed in well-stopped bottles, in which they should be preserved. When long kept, they are apt to form a viscid ropy matter, and to become sour. This result has been ascribed to other principles, which rise with the oil in distillation, and promote its decomposition. To prevent this decomposition, the *Edinburgh College* ordered rectified spirit to be added to the water employed in the process of distillation. But this addition is inadequate to the intended object, and is in fact injurious, as the alcohol by long exposure to the air appears to undergo the acetous fermentation. The *London College*, which had previously directed a spirituous addition, abandoned it in the last edition of their Pharmacopœia; and it is not directed in any of the present U. S. or British formulas in which distillation is performed. A better plan is to redistil the Waters. When thus purified, it is said that they may be kept for several years unchanged.

Robiquet considers the mucosity which forms in Distilled Waters as the result of a vegetative process, to which the presence of air is essential. He has found that, so long as the water is covered with a layer of essential oil, it undergoes no change; but that the oil is gradually altered by exposure to the air, and, as soon as it disappears, the water begins to be decomposed. He states that camphor exercises the same preservative influence over the Distilled Waters by resisting the vegetation, and that those in which the odour of camphor is developed keep better on that account. Finally, he has observed that the more Distilled Water is charged with volatile oil, the more abundant is the mucosity when

* Distillation by steam having been demonstrated, in France, to be the best method of preparing the Distilled Waters in all instances, we present, in the margin, the figure of a vertical section of Soubeiran's apparatus for this purpose, somewhat modified. A cylindrical tinned copper or iron boiler (*A*), three and a half feet high and two in diameter, is surmounted by an expanded head or capital (*B*) which is furnished with an inner ledge, forming a kind of gutter, intended to receive the liquid condensed on the inner surface of the capital, and opening into the exit tube (*e*). Across the boiler, about six inches from the bottom, is placed a horizontal septum or diaphragm, pierced with numerous small holes. Through the side of the boiler, near the top, a steam pipe (*a d*), provided with a stop-cock (*a*), enters, and, turning immediately downwards, runs along the side of the boiler to the bottom, where it makes a horizontal bend, and, extending to the middle of the base, turns upwards, and opening by a perforated expansion, like the end of the spout of a watering pot, terminates a little beneath the centre of the diaphragm. The material to be distilled, having been previously properly comminuted, and macerated when necessary, is introduced into the boiler, and rests on the diaphragm. The capital, having then been applied, and secured by a luting of linen bands coated with dextrin paste, steam from any convenient generator is admitted through the tube at its upper extremity, and passing down, escapes through the expanded termination (*b*) beneath the diaphragm, through the small openings of which it passes, and thus penetrates equably all parts of the material. Loaded with the volatile matters, it then rises into the capital, where a portion being condensed falls into the gutter, and the remainder passes out, with the liquid condensed in the capital, through the exit pipe (*f*), whence it enters into a worm or other suitable condensing apparatus. (*Note to the twelfth edition.*)

it has begun to form. Robiquet unites with Henry and Guibourt, and with Virey, in recommending that all these Waters, when intended to be kept for a considerable time, should be introduced, immediately after distillation, into bottles of a size proportionate to the probable consumption of the water when brought into use; and that the bottles should be quite filled, and then sealed or otherwise well stopped, so as entirely to exclude the air. It is best that they should be small, and be closed with well-fitting glass stoppers. Thus treated, the Waters may be preserved without change for many years. (*Journ. de Pharm.*, xxi. 402.) If this plan be not put into operation immediately, the Water should, after introduction into the bottle, be heated to about 212° by placing the bottle in boiling water, and, when it begins to run over, should be carefully enclosed.*

Another mode of preparing the Distilled Waters is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed in the British Pharmacopœia, in several instances. It is said to afford a more permanent product than the preceding; but does not always preserve the flavour of the plant.

In relation to most of the aromatics, the U. S. Pharmacopœia discards altogether the process by distillation, and directs that water should be impregnated with the volatile oil by trituration with carbonate of magnesia, and subsequently filtered. This is by far the most simple and easy process. The resulting solution is pure and permanent, and is perfectly transparent, the carbonate of magnesia being separated by the filtration. Carbonate of magnesia is preferable to the pure earth; as the latter sometimes gives a brownish colour to the liquid, and requires to be used in larger proportion. But both these substances are dissolved in minute quantities, and are apt to occasion a slight flocculent precipitate. They may also possibly prove injurious by decomposing certain substances given in very small doses, as sulphate of morphia, bichloride of mercury, and nitrate of silver. The object of the magnesia or its carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. According to Mr. Robert Warington, this object may be better accomplished by porcelain clay, finely powdered glass, or pumice stone, which are wholly insoluble (*Chem. Gaz.*, March, 1845, p. 113); and the London College employed finely powdered silica for the purpose. Chalk and sugar answer the same end; but the latter, by being dissolved with the oil, renders the preparation impure. The *Dublin College* prepared its Waters by agitating an alcoholic solution of the oil with distilled water, and filtering. They consequently contained alcohol, and were liable to the objection, already mentioned, against the medicated waters thus impregnated. They were besides feeble in the properties of their respective oils. In the preparation of the aromatic waters by these processes, it is very important that the water should be pure. The presence of a sulphate causes a decomposition of the oil, resulting in the production of sulphuretted hydrogen and a carbonate; and the aromatic properties are quite lost. (See *Am. Journ. of Pharm.*, xix. 303.) Hence the propriety of the officinal direction to employ distilled water.†

* It is of some importance to know the proportion which the aromatic submitted to distillation ought to bear to the amount of distilled water obtained. The following statement upon this point, based upon experiments, is contained in the *Journal de Pharmacie* (Mai, 1861, p. 367). Fresh aromatic plants requiring one part of the plant for one of product; wormwood, black cherry, scurvy-grass, hyssop, cherry-laurel, lavender, balm, mint, peach-leaves, roses, and sage;—fresh and dry aromatics requiring one part of the plant to two of product; bitter almonds, orange-flowers, melilot, horseradish, elder, and tansy;—dry and very aromatic plants requiring one part to four of product; angelica, green anise, juniper berries, chamomile, canella, cascarilla, fennel, sassafras, linden flowers, and valerian. (*Note to the twelfth edition.*)

† Mr. Haselden prefers the process of distillation from the aromatic itself in the instances of dill, caraway, fennel, cinnamon, and pimento, which are not apt to afford to the distilled water such matter as may cause it to become sour; but he thinks that peppermint, spearmint, and pennyroyal waters may be advantageously prepared by trituration. He advises, however, that these waters should not be filtered, but prepared in quantity, allowed to settle, and drawn off as wanted. (*Pharm. Journ.*, xvi. 14, 15.)—*Note to the eleventh edition.*

The Distilled Waters are liable to contain various metallic impurities, derived from the vessels in which they are prepared or preserved. The metallic salts which have been found in them are those of iron, zinc, copper, and lead. With ferrocyanide of potassium iron will give a blue colour, zinc and lead white precipitates, and copper a rose-colour followed by chestnut-brown. Sulphuret of sodium causes with the salts of iron, copper, and lead, a brown discoloration more or less deep, followed by precipitates varying from brown to black; with those of zinc, a white precipitate. The Distilled Waters may be freed from these impurities by animal charcoal, previously well purified. The charcoal should be strongly shaken, eight or ten times in the course of a day, with the impure Water, which should then be allowed to rest, and the next day be filtered. Five grains of the charcoal will be sufficient for a gallon of the Distilled Water. (*Journ. de Pharm.*, Nov. 1862, p. 416.) The volatile oils may be recovered from the Waters containing them, or at least may be transferred to a spirituous menstruum, by mixing olive oil with the water, adding a little solution of potassa so as to form a soap, and a consequent emulsion with the liquid, and then neutralizing by an acid. The fixed oil will rise to the surface, bringing the volatile oil along with it. The latter may then be separated from the former by agitation with alcohol. (T. B. Groves, *Pharm. Journ.*, Feb. 1864.) W.

AQUA ACIDI CARBONICI. *U. S. Carbonic Acid Water. Artificial Seltzer Water.*

"By means of a proper apparatus, impregnate Water, contained in a suitable receiver, with a quantity of carbonic acid, equal to five times the bulk of the Water. Carbonic acid may be obtained from Bicarbonate of Soda or from Marble by means of dilute sulphuric acid." *U. S.*

This preparation, which is peculiar to the United States Pharmacopœia, consists of water highly charged with carbonic acid. Water is found to take up its volume of this acid under the pressure of the atmosphere; and Dr. Henry ascertained that precisely the same *volume* of the compressed gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. A double pressure will force a double quantity into a given space, and, therefore, cause a double quantity to be absorbed; a treble pressure will drive a treble quantity into the same space, and cause its absorption; and so on for higher pressures, the *bulk* of the *compressed* gas absorbed always remaining the same. From the principles above laid down it follows that, to saturate water with five times its volume of carbonic acid, as directed in the formula, it must be subjected to a pressure of five atmospheres.

M. Ozouf, of Paris, has put in operation a new mode of preparing carbonic acid, on the large scale, for the manufacture of artificial mineral waters. It consists in the passage of carbonic acid from the vigorous combustion of coke, refrigerated and washed, through a solution of carbonate of soda, and heating the solution of bicarbonate of soda thus formed so as to drive off its carbonic acid, which is collected for use. The solution of the carbonate of soda thus produced, after refrigeration, is again used in the process, and thus indefinitely. A peculiar arrangement of apparatus is employed for the purpose, which is described in the *Journ. de Pharm. et de Chim.* (Avril, 1868, p. 265).

Carbonic acid water is familiarly called in this country "*mineral water*," and "*soda water*;" the latter name, originally applied to the preparation when it contained a small portion of carbonate of soda, being from habit continued since the alkali has been omitted. As it is largely consumed both as an agreeable beverage and as a medicine, we give, in a note below, a sketch of an approved apparatus employed in this city for its preparation.*

* The apparatus referred to in the text consists of a strong egg-shaped copper vessel, tinned on the inside, about eighteen inches long, called a generator, fixed upright in a wooden frame, and surmounted by another upright vessel of similar shape, about nine

Carbonic acid water is dispensed in many of the apothecary shops in this country. The fountain is usually placed in the cellar, and the tube proceeding from the fountain is made to pass through the floor and counter of the shop, and to terminate in a stop-cock, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool in summer, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, placed under the counter and surrounded with ice, and from this vessel a separate tube penetrating the counter proceeds.

Properties. Carbonic acid water is a sparkling liquid, possessing an agreeable, pungent, acidulous taste. It reddens litmus deeply from its state of concentration, and is precipitated by lime-water. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its briskness, it should be kept in strong well-corked bottles, placed inverted in a cool place. Several natural waters are of a similar nature; such as those of Seltzer, Spa, and Pyrmont; but the artificial water has the advantage of a stronger impregnation with the acid gas. Carbonic acid water should be made with every precaution to avoid metallic impurity. Hence the necessity of having the fountain well tinned on the inner surface. Even with this precaution, a slight metallic impregnation is

inches long, communicating with the generator by a short neck, and intended to contain the sulphuric acid. Connected with the generator by a copper tube, and placed by its side, is a strong cylindrical vessel for washing the gas, about fifteen inches long and three and a half in diameter, two-thirds filled with water, and to near the bottom of which the connecting tube passes. Severally communicating with the washing vessel are a mercurial gauge to indicate the pressure, and a strong vessel, called the reservoir or fountain, of about the capacity of eighteen gallons, three-fourths filled with water, the connection of the latter being by a lead or gutta-percha tube, commanded by a stop-cock. The charge of whiting or marble dust, say eight pounds, and the requisite water are added through an opening in the generator, in front of the sulphuric acid vessel, and closed by a screw stopper. The communication between the acid vessel and generator is commanded by a vertical square rod, reaching within the vessel to about two-thirds of its height, and terminating at its lower end in a screw. This rod, when unscrewed, opens a communication between the acid vessel and the generator. The requisite sulphuric acid is added to the acid vessel through an opening at its top, capable of being closed by a screw stopper. Through the axis of this stopper, and revolving within it, but without having any vertical motion, passes the key, in the lower end of which there is a square hole to fit on the square rod. When the acid vessel is to be closed, the screw stopper, with its key, is placed over the opening, in which situation the lower end of the key reaches down a sufficient distance to embrace loosely the square rod. The stopper is now screwed in, and the key, without revolving with the stopper, descends so as duly to embrace the square rod. By turning the handle of the key in the proper direction, the rod is partially unscrewed, the passage to the generator opened, and the acid gradually flows in. From time to time, when the acid is allowed to enter the generator, its contents are briskly mixed by means of an agitator, attached to a horizontal axis, passing air-tight through the short diameter of the generator, and turned by a crank. The stop-cock between the washing vessel and fountain is now partially opened, and the impregnation of the water with the gas begins. As it proceeds, the sulphuric acid is gradually allowed to enter the generator until it is expended, and the stop-cock is from time to time turned, until it is entirely opened. Finally, after the water is fully charged with gas, and the whiting wholly decomposed, the fountain is detached, and the generator freed from the pulpy sulphate of lime by the assistance of water and the agitator, and its contents allowed to escape through an opening in its most depending part. In the apparatus of the size above described, a single fountain only is charged by one operation, and the carbonic acid water formed contains between nine and ten times its volume of the gas. In this mode of making carbonic acid water, it is perceived that the requisite pressure is obtained by generating the carbonic acid in a confined space.

Numerous other forms of apparatus have been invented for making carbonic acid water. That of Bernhard is figured in the *Am. Journ. of Pharmacy* for Jan. 1856; the figure being taken from *Parrish's Pharmacy*. In this apparatus, the generators and washing vessels are of thickly tinned copper, and the fountains, of cast iron lined with enamel. These fountains are free from objection except for their weight; as also are the stoneware fountains, strengthened with iron bands, which are used in Boston. A less costly apparatus than the above is Nicholl's patent combination fountain, figured in the same journal for March, 1856. In this, bicarbonate of soda is used instead of whiting, and the salt is added to the acid, instead of the acid to the salt. For an account of the small apparatus of Mr. R. Knight, which is made of tin and silver exclusively, see the *Pharm. Journal* for May, 1857.

not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the tubes and stop-cocks. Glass fountains are sometimes used with advantage at this season; and a patent has been taken out for a stoneware fountain, enclosed in tinned copper, which is said to answer a good purpose. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. A case of colica pictonum was treated by one of the authors, arising from the daily use of the first draught of carbonic acid water from a fountain furnished with tubes of lead. Tubes of pure tin, enclosed in lead ones to give them strength, are free from objection.

Copper fountains, well tinned, are liable to the objections that the tin lining wears away by use, and that there is no convenient means of inspecting their interior, owing to the solder joint, which permanently unites the two sections of the fountain. To remove the latter objection, the improvement has been proposed by Dr. R. O. Doremus, of New York, to have the two sections with flanges, securely bolted together, with intervening gutta-percha packing, in order to furnish facilities for examining the interior, to determine whether re-tinning is necessary. Sometimes drops of solder and chips of copper are carelessly left in the fountain, and form an additional source of danger. There can be no doubt that carbonic acid water is not unfrequently rendered poisonous by metallic impregnation. Dr. Doremus has proved, by a chemical examination, that lead and copper are sometimes present. (*Am. Journ. of Pharm.*, Sept. 1854, p. 422; from the *Am. Med. Monthly.*) Dr. John T. Plummer, of Richmond, Ind., has found lead. The latter metal is detected by sulphuretted hydrogen, which gives with it a black precipitate, and copper by ferrocyanide of potassium, which causes a brown precipitate. In testing for copper, a few drops of the reagent should be added to a glass of the suspected water, placed on a sheet of white paper when, if even a minute proportion of copper be present, a brownish discoloration will be seen, upon looking down through the liquid.

Carbonic acid, formerly called *fixed air*, is a colourless gas, of a slightly pungent odour and acid taste. It reddens litmus feebly, and combines with salifiable bases, forming salts called carbonates, from which it is expelled by all the strong acids. It extinguishes flame, and is quickly fatal to animals when respired. All kinds of fermented liquors which are brisk or sparkling, such as champagne, cider, porter, &c., owe these properties to its presence. Its sp. gr. is 1·52. In 1823 it was liquefied by Faraday by a pressure of 36 atmospheres, and in 1836 solidified by Thilorier, by taking advantage of the cold generated by the sudden gasefaction of the liquid acid, when freed from pressure. It is composed of one eq. of carbon 6, and two of oxygen 16 = 22 (CO_2).

Medical Properties and Uses. Carbonic acid water is diaphoretic, diuretic, and anti-emetic. It forms a grateful drink to febrile patients, allaying thirst, lessening nausea and gastric distress, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, sulphate of magnesia, and the saline cathartics generally; rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces will be sufficient.

Carbonic acid gas was observed to act as a local anæsthetic in ulcerated cancer, so early as 1794, by Dr. John Evart, of Bath. In 1834 it was first used by Prof. Mojon, of Geneva, in dysmenorrhœa, and with the most soothing effect. Since then it has been employed with good effect, in certain painful affections of the uterus, by Prof. Simpson, of Edinburgh, and M. Follin, of Paris. M. Follin, M. Demarquay, and M. Monod have found it particularly useful in relieving the pain in cancer of the uterus and vagina. The first effect of the gas is a sensation of pricking and heat. Another application of carbonic acid by injection is for the production of premature labour. For this purpose it has been successfully employed by Prof. Scanzoni, of Wurzburg, and Prof. Simpson, of

Edinburgh. According to Prof. Simpson, the gas is most conveniently generated by mixing, in a bottle, six drachms of crystallized tartaric acid with eight drachms of bicarbonate of soda, dissolved in six fluidounces of water. B.

AQUA AMMONIÆ. *U.S.* LIQUOR AMMONIÆ. *Br.*, *U.S.* 1850. *Water of Ammonia. Solution of Ammonia.*

"Take of Muriate of Ammonia, in small pieces, Lime, each, *twelve troyounces;* Water *six pints;* Distilled Water *a sufficient quantity.* Pour a pint of the Water upon the Lime, in a convenient vessel; and, after it has slaked, stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Muriate of Ammonia. Place the retort on a sand-bath, and adapt to it a receiver, previously connected with a two-pint bottle, containing a pint of Distilled Water, by means of a glass tube, reaching nearly to the bottom of the bottle. Surround the bottle with ice-cold water; and apply heat, gradually increased, until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient Distilled Water to raise its specific gravity to 0·960. Lastly, keep the liquid in small bottles, well stopped." *U. S.*

"Take of Strong Solution of Ammonia *one pint* [Imperial measure]; Distilled Water *two pints* [Imp. meas.]. Mix, and preserve in a stoppered bottle. Sp. gr. 0·959." *Br.*

The title of this preparation was changed, at the late revision of the U. S. Pharmacopœia, from Liquor Ammoniæ to Aqua Ammoniæ, that it might conform in name as well as character with the Waters, among which all the officinal preparations consisting of aqueous solutions of gaseous bodies are included.

The object of the above processes is to obtain a weak aqueous solution of the alkaline gas ammonia. In the U. S. process, the muriate of ammonia is decomposed by the superior affinity of the lime for its acid, ammonia is disengaged, and the lime, combining with the acid, forms chloride of calcium and water. The process differs from that of 1850 in introducing the materials into the retort with a large quantity of water, instead of in the dry state. In both cases the gas is driven over by heat, but in the moist plan is accompanied with more watery vapour than in the dry. If the object were to obtain the water of ammonia in the highest possible state of concentration, there might be some advantage in the dry method; but, as a weak solution is contemplated, the wet method is equally efficient, while in all respects more convenient, and productive of better results; for, according to Dr. Squibb, the water of ammonia made by the former officinal process has invariably an empyreumatic odour, from which that made by the present process is free. (*Proceed. of the Am. Pharm. Assoc.*, 1858, p. 407.) The receiver is intended to retain any water holding in solution undecomposed muriate, or the oily matter sometimes contained in the salt, as well as other impurities, which may be driven over by the heat while the pure gas passes forward into the bottle containing the distilled water, which should not fill it, on account of the increase in the bulk of the water during the absorption of the gas. The tube should extend to near the bottom of the bottle, and pass through a cork, loosely fitting its mouth. To prevent the regurgitation of the water from the bottle into the intermediate vessel, the latter should be furnished with a Welter's safety tube. Large bottles are improper for keeping the water of ammonia; as, when they are partially empty, the atmospheric air within them may furnish a little carbonic acid to the ammonia.

In preparing solution of ammonia, equal weights of muriate of ammonia and lime are used for generating the gaseous ammonia. This proportion gives a great excess of lime, compared with the quantity required if determined by the equivalents; but in practice it is found advantageous to have an excess, as well to ensure the full decomposition of the muriate of ammonia, as to make up for accidental impurities in the lime.

The British Pharmacopœia gives directions for diluting *Liquor Ammoniæ Fortior*, so as to reduce it to the strength of *Liquor Ammoniæ*. This is effected

by mixing one measure of their stronger preparation with two measures of distilled water.

Properties. The properties of Liquor Ammoniæ Fortior have already been given. (See *page* 106.) Those of the officinal solution of ammonia, described in this place, are the same in kind, but weaker in degree. It should be quite free from empyreuma. Its sp. gr. in the U. S. Pharmacopœia is said to be 0·960; in the British, 0·959. When of the density 0·960, 100 grains of it saturate 30 grains of officinal sulphuric acid, and contain nearly 10 grains of ammonia. Of the British preparation, "85 grains by weight require for neutralisation 500 grain-measures of the *volumetric solution of oxalic acid*, corresponding to 10 per cent. by weight of ammonia, NH_3. One fluidrachm contains 5·2 grains of ammonia." *Br.* It is incompatible with acids, and with acidulous and many earthy and metallic salts; but it does not decompose the salts of lime, baryta, or strontia, and only partially decomposes those of magnesia. If precipitated by lime-water, the ammonia is partly carbonated. When saturated with nitric acid, it should give no precipitate with carbonate of ammonia, nitrate of silver, or chloride of barium. A precipitate with the first indicates earthy matter; with the second, muriatic acid or a chloride; with the third, sulphuric acid or a sulphate. Commercial solution of ammonia sometimes contains *pyrrol*, *naphthalin*, and other soluble impurities. These may be detected by the solution being reddened by nitric acid, and, after having been supersaturated with muriatic acid, by its tinging a slip of fir wood of a rich purple colour, characteristic of pyrrol. (*Maclagan.*) The source of these impurities is coal-gas liquor, from which the ammoniacal compounds are largely obtained.

Composition. Water is capable of absorbing 670 times its volume of ammoniacal gas at 50°, and increases in bulk about two-thirds. But the officinal solution of ammonia is by no means a saturated one. Thus, the ammonia contained in the U. S. preparation is about 10 per cent. The following table gives the percentage of ammoniacal gas in aqueous solutions of different densities.

Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.
0·8750	32·50	0·9326	17·52	0·9545	11·56
0·8875	29·25	0·9385	15·88	0·9573	10·82
0·9000	26·00	0·9435	14·53	0·9597	10·17
0·9054	25·37	0·9476	13·46	0·9619	9·60
0·9166	22·07	0·9513	12·40	0·9692	9·50
0·9255	19·54				

Medical Properties and Uses. Water of ammonia is stimulant, sudorific, antacid, and rubefacient. It stimulates more particularly the heart and arteries, without unduly exciting the brain. As a stimulant it is occasionally employed in paralysis, hysteria, syncope, asphyxia, and similar affections. In the same complaints it is often applied to the nostrils with advantage; but, in cases of insensibility, care must be taken not to carry the application too far, for fear of inducing dangerous and even fatal bronchitis. As an antacid, it is one of the best remedies in heartburn, and for the relief of sick headache when dependent on gastric acidity. In these cases it acts usefully also by stimulating the stomach. In the bites of poisonous serpents, it has long been deemed a powerful antidote. A case, caused by the bite of a cobra de capello, was successfully treated by Dr. W. Chalmers, formerly of Bengal, in which solution of ammonia was chiefly relied on. A dose of this solution, given in drunkenness, is said to remove the intoxication in a short time. A case of traumatic tetanus, in the care of Dr. Charbonnier, recovered under the use of six drops of water of ammonia given every half hour. (*Lancet*, July, 1867, p. 26.) It has been recommended by Dr. Guérard as an application to burns, attended with rubefaction or vesication, in order to relieve the pain and hasten the cure. (*Journ. de Pharm.*, Jan. 1849.) As a rubefacient it is employed united with oils in the form of volatile liniment. (See *Linimentum Ammoniæ.*) The dose is from ten to thirty drops,

largely diluted with water to prevent its caustic effect on the mouth and throat. When swallowed in an overdose, its effects are those of a corrosive poison. A case is recorded in the *Journal de Pharmacie* (Avril, 1862, p. 324), in which about three fluidounces were swallowed, with a fatal result in eight days, after great suffering, and various local and systemic disorder. Dissection exhibited signs of inflammation and corrosion of the œsophagus and stomach, with great enlargement and softening of the mesenteric glands and kidneys. The best antidotes are vinegar and lemon juice, which act by neutralizing the ammonia, and must be promptly applied to be useful. The consecutive inflammation must be treated on general principles.

AQUA AMYGDALÆ AMARÆ. *U. S. Bitter Almond Water.*

"Take of Oil of Bitter Almonds *sixteen minims;* Carbonate of Magnesia *sixty grains;* Water *two pints.* Rub the Oil, first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper." *U. S.*

This preparation has the effects of hydrocyanic acid on the system, and may be used as a vehicle of other medicines in nervous coughs, and various spasmodic affections. It is, however, liable to spontaneous change, and is consequently more or less uncertain. A drop of sulphuric acid added to a pint of it will contribute to its preservation; as will also complete exclusion from the light and air. But the better plan is to prepare it in small quantities, as wanted for use. The dose of it, to begin with, when of full strength, should not exceed half a fluidounce. Under the same name, a preparation has been much used on the continent of Europe, prepared by distilling bitter almonds with water. This when fresh is much stronger than the preparation of the U. S. Pharmacopœia, containing, according to an analysis of Geiger, in 1000 parts, 1·2 parts of anhydrous hydrocyanic acid. But, in consequence either of circumstances in the manner of its preparation, or of changes upon being kept, it is of variable and uncertain strength, and cannot be relied on. It has been prescribed with fatal effects; and the greatest caution, therefore, should be observed by the apothecary not to put up the distilled water instead of the officinal.* W.

* In an experiment performed by M. Mayet, one kilogramme (about two avoirdupois pounds) of bitter almond cake from which the fixed oil had been separated, having been finely powdered, and mixed with enough water to form a thin paste, was kept for a day at the temperature of 86° F., and then submitted to distillation by means of steam, with the following results. The products of distillation were collected in separate portions successively, each of 500 grammes (about a pint). The first portion was milky, immediately after distillation, but in two hours became clear, without the separation of oil; the others were limpid from the beginning. The first contained 0·250 per cent. of hydrocyanic acid, the second 0·070 per cent., the third 0·030, and the fourth 0·024 per cent. The mean of these (0·093) exceeded the percentage obtained by testing a mixture of the four in equal parts, which was only 0·088, owing to the necessity, in each examination, of slightly passing the point of saturation before catching with the eye the blue tint that indicates it. M. Mayet thinks, from these premises, that 0·08 per cent., or 80 milligrammes for 100 grammes, would be the proper mean to establish in regulating the strength of the bitter almond water, if two parts of product are to be obtained from one of the dry material employed. He would, however, prefer stopping the process when one part and a half had been obtained, in which case a 0·110 per cent. product might be procured, and it would be easy to fix the mean at 0·100 per cent. M. Mayet also satisfied himself that distillation by steam is decidedly preferable in this process to that by the naked fire, provided that *linen coated with dextrin* be employed for luting the apparatus, instead of common paper luting, which does not sufficiently resist steam. (*Journ. de Pharm.*, Juillet, 1861, p. 18.)—*Note to the twelfth edition.*

AQUA ANETHI. *Br. Dill Water.*

"Take of Dill Fruit, bruised, *one pound* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

This is seldom if ever used in the United States. W.

AQUA AURANTII FLORUM. *U. S.* Aqua Aurantii Floris. *Br. Orange Flower Water.*

"Take of Orange Flowers *forty-eight troyounces;* Water *sixteen pints.* Mix them, and distil eight pints." *U. S.*

This preparation is considered by the British Pharmacopœia as an object of importation. According to this authority, it is obtained indiscriminately from the flowers of the bitter and those of the sweet orange tree; and the same is the case with our own officinal standard; though, in Italy and France, where it is largely made, the flowers of the bitter orange are preferred, as yielding the most fragrant product. It may be prepared in the most Southern districts of our country from the fresh flowers; and these might be brought to the North for the same purpose, if previously incorporated with one-third or one-quarter of their weight of common salt. The proper method is to arrange the flowers and salt in successive layers in jars of stoneware or glass. They may also be preserved by means of glycerin. (See *page* 1029.) Notwithstanding, however, the facility of preparing this Water here, it is generally imported from the South of France, whence it often comes in cans of tinned copper.

Orange flower water is nearly colourless, though usually of a pale yellowish tint. From being kept in copper bottles, it sometimes contains metallic impurity, which is said to be chiefly carbonate of lead, derived from the lead used as a solder in making the bottles. The means of detecting metallic impurity are mentioned under the general observations on distilled waters, *page* 1033. If it contain lead, sulphuretted hydrogen will produce with it a dark precipitate. Much colour, offensive odour, or mouldiness indicates impurity derived from the flowers in distillation.

A distilled water of the leaves is also prepared; and sometimes a mixture of the leaves and flowers is employed. But this is a fraud, as the distilled water of the leaves never has the sweet perfume of that of the flowers. (*Journ. de Pharm.*, 4e sér., iii. 249.)

Orange flower water is used exclusively on account of its agreeable odour; though it may possess slight powers as a nervous stimulant.

Off. Prep. Syrupus Aurantii Florum, *U. S.;* Syrupus Aurantii Floris, *Br.* W.

AQUA CAMPHORÆ. *U. S., Br. Camphor Water.*

"Take of Camphor *one hundred and twenty grains;* Alcohol *forty minims;* Carbonate of Magnesia *half a troyounce;* Distilled Water *two pints.* Rub the Camphor, first with the Alcohol, then with the Carbonate of Magnesia, and lastly with the Water gradually added; then filter through paper." *U. S.*

"Take of Camphor, broken into pieces, *half an ounce* [avoirdupois]; Distilled Water *one gallon* [Imperial measure]. Enclose the camphor in a muslin bag, and attach this to one end of a glass rod, by means of which it may be kept at the bottom of a bottle containing the Distilled Water, the other end of the rod terminating just below the stopper of the bottle. Having thus put the Camphor into the Water, close the mouth of the bottle for at least two days, and then pour off the solution when it is required." *Br.*

In these processes the object is to effect a solution of the camphor. Water is capable of dissolving but a small proportion of this principle; but the quantity varies with the method employed. The present British process is still more inefficient than the old formulas of the different Colleges for their *Mistura Camphoræ*, which has received in the late revision a much more appropriate name. In the *London* process the camphor was first rubbed with a little spirit to powder it, and then with water; in the *Edinburgh*, sugar and almonds were used as an intermedium by which the water might be induced to take up the cam-

phor; in the *Dublin*, the spirit of camphor was shaken with water. All of them produced very weak preparations. In the present British process no trouble is taken even to comminute the camphor, or to shake it with the water, which is thus allowed to take up what it may be disposed to do by contact with the camphor contained in a bag; though some ingenuity is exhibited in retaining the latter, which is lighter than water, beneath the surface of the liquid by means of a glass rod. The solution thus effected must be extremely feeble, containing probably less than one part in a thousand, which, according to Berzelius, is taken up by water when triturated with camphor. It is besides of uncertain strength, varying with the size of the fragments of camphor. Mr. J. C. Pooley found that 120 grains of camphor, treated according to the officinal directions, gave, when cut into 4 pieces, 6 grains to half a gallon of water, but in 20 pieces gave 20 grains, or about one part to 1750 of water. (*Pharm. Journ. and Trans.*, 2d ser., vii. 162.) Our own officinal preparation, when properly made, contains about 50 grains to the pint, or more than 3 grains in each fluidounce. (*Journ. of the Phil. Col. of Pharm.*, iv. 13.) This, however, is denied by Mr. G. F. H. Markoe, who, as the result of his experiments, gives the proportion of camphor in the U. S. preparation as only 2 grains in the fluidounce. (*Am. Journ. of Pharm*, March, 1866, p. 168.) Care should be taken to rub all the water, in successive portions, with the mixture of camphor and carbonate of magnesia. The comparative strength of the U. S. preparation is attributable, at least in part, to the minute division effected in the camphor by trituration with the carbonate of magnesia, which is afterwards separated by filtration. The use of the alcohol is simply to break down the cohesion of the camphor, and enable it to be more easily pulverized. This process is much preferable to the British, as it affords a permanent solution, of sufficient strength to be employed with a view to the influence of the camphor on the system; while the other has little more than the flavour of the narcotic, and is fit only for a vehicle of other medicines. The camphor is separated by a solution of pure potassa, and, according to Dr. Paris, by sulphate of magnesia and several other salts. Sir J. Murray proposes a solution of camphor and bicarbonate of magnesia, which contains three grains of the former and six grains of the latter in each fluidounce.

Camphor water is employed chiefly in low fevers and typhoid diseases, attended with restlessness, slight delirium, or other symptoms of nervous derangement or debility. It is used also to allay uterine after-pains. It has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is not applicable to cases where very large doses of the medicine are required. It is usually given in the dose of one or two tablespoonfuls repeated every hour or two hours. W.

AQUA CARUI. *Br. Caraway Water.*

"Take of Caraway Fruit, bruised, *one pound* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

Distilled caraway water has the flavour and pungency of the seeds, but is seldom used in this country. The preparation employed here is usually made from the volatile oil, in the same manner as cinnamon water. (See *Aqua Cinnamomi.*) W.

AQUA CHLORINII. *U. S.* Liquor Chlori. *Br. Chlorine Water. Solution of Chlorine.*

"Take of Black Oxide of Manganese, in fine powder, *half a troyounce;* Muriatic Acid *three troyounces;* Water *four fluidounces;* Distilled Water *twenty fluidounces.* Introduce the Oxide into a flask, add the Acid previously diluted with two fluidounces of the Water, and apply a gentle heat. Conduct the generated chlorine, by suitable tubes, through the remainder of the Water contained in a small intermediate vessel, to the bottom of a four-pint bottle containing the Distilled Water, and loosely stopped with cotton. When the air has been entirely displaced by the gas, disconnect the bottle from the ap-

paratus, and, having inserted the stopper, agitate the contents, loosening the stopper from time to time, until the gas ceases to be absorbed. Lastly, pour the Chlorine Water into a bottle, of just sufficient capacity to hold it, stop it securely, and keep it in a cool place, protected from the light." *U. S.*

"Take of Hydrochloric Acid *six fluidounces* [Imperial measure]; Black Oxide of Manganese, in fine powder, *one ounce* [avoirdupois]; Distilled Water *thirty-four fluidounces* [Imp. meas.]. Put the Oxide of Manganese into a gas-bottle, and, having poured upon it the Hydrochloric Acid diluted with two [fluid]ounces of the Water, apply a gentle heat, and, by suitable tubes, cause the gas, as it is developed, to pass through two [fluid]ounces of the Water placed in an intermediate small phial, and thence to the bottom of a three-pint bottle containing the remainder of the Water, the mouth of which is loosely plugged with tow. As soon as the chlorine ceases to be developed, let the bottle be disconnected from the apparatus in which the gas has been generated, corked loosely, and shaken until the chlorine is absorbed. Lastly, introduce the solution into a green glass bottle furnished with a well-fitting stopper, and keep it in a cool and dark place." *Br.*

The U. S. and Br. processes are essentially the same; and both were copied from the late Dublin process. The only material variation in the British formula is the somewhat larger proportion of the black oxide of manganese and muriatic acid, to the distilled water; an avoirdupois ounce of the oxide and six fluidounces of the acid having been substituted for half the quantity of each as directed by the Dublin College, while the distilled water used by the former is only thirty-four fluidounces to twenty-four by the latter, of which quantities four fluidounces are taken by each in the preliminary steps of the process, and the remainder used for the absorption of the chlorine. In the U. S. formula, the proportions differ from those of the Dublin, in the use of the troyounce both for the oxide of manganese and the acid, instead of the avoirdupois ounce for the former and the fluidounce for the latter. The British process differs from both in directing the disconnection of the apparatus for generating the gas, as soon as it ceases to be produced, instead of after the air in the receiving bottle has been displaced by it. Should there be any danger of deficiency of chlorine in the resulting chlorine water, the British process would have the advantage, as it uses not only a larger proportion of the materials for making the gas, but exhausts them.

In the U. S. process, four fluidounces of common water are used in the dilution of the muriatic acid, and for absorbing the impurities in the intermediate vial. The twenty fluidounces of distilled water are placed in a four-pint bottle, which it about one-third fills. In both processes, the chlorine gas is extricated from the muriatic acid by the deutoxide of manganese separating the hydrogen, and is passed, through an intermediate vessel containing a little water for purifying it, into the four-pint bottle, loosely stopped, until the vacant part of the bottle is filled with it to the exclusion of the atmospheric air. The bottle being then corked, is shaken so as to cause the absorption of the gas by the water. Of course the stopper must be from time to time loosened, in order to allow the entrance of air to supply the partial vacuum created by the absorption of the chlorine. The product is about a pint and a quarter of the chlorine water, which is transferred to a bottle just sufficient in capacity to hold it. The chlorine water is directed to be kept secluded from the light, because otherwise it would be apt to be converted partially into muriatic acid, through the union of the chlorine with the hydrogen of the water. In the Br. Pharmacopœia it is ordered to be kept in a green glass bottle, for the purpose, probably, of protecting it from the light; but recent experiments have shown that it is an orange, and not a green colour, which appears to prevent the passage of the chemical rays.

Properties. Chlorine water has a pale yellowish-green colour, an astringent taste, and the peculiar odour of the gas. Like gaseous chlorine it destroys vegetable colours. When cooled to about the freezing point, it forms deep-yellow crystalline plates, consisting of hydrate of chlorine. It is intended to contain at

least twice its volume of the gas. It is decomposed by light, with the production of muriatic acid, and the evolution of oxygen, and hence must be kept in a dark place. According to MM. Riegel and Walz, chlorine water, containing two and a half volumes of the gas at 54°, keeps best. The U. S. Pharmacopœia gives as a test of its strength in chlorine, that "when a fluidounce of it is mixed with a solution of 10 grains of pure sulphate of protoxide of iron in two fluidrachms of water, the mixture does not produce a blue precipitate with ferridcyanide of potassium (red prussiate of potassa)." This shows that there is sufficient chlorine in the Water to peroxidize the protoxide of iron of the protosulphate; as, though the protosalts of iron do, the persalts do not produce a blue precipitate with the ferridcyanide. The British solution "immediately discharges the blue colour of a dilute solution of indigo. Its sp. gr. is 1·003, and when evaporated it leaves no residue. When 20 grains of iodide of potassium, dissolved in a [fluid]ounce of distilled water, are added to 439 grains by weight (one fluidounce) of this preparation, the mixed solution acquires a deep-red colour, which requires for its discharge 750 grain-measures of the *volumetric solution of the hyposulphite of soda*, corresponding to 2·66 grains of chlorine." *Br.* This indicates the quantity of chlorine in the solution, by the amount of the hyposulphite required to decolorize an equivalent quantity of iodine, liberated from the iodide of potassium.

Chlorine is an elementary gaseous fluid, of a greenish-yellow colour, and characteristic smell and taste. It is a supporter of combustion. Its specific gravity is 2·47, and equivalent number 35·5. When the attempt is made to breathe it, even much diluted, it excites cough and a sense of suffocation, and causes a discharge from the mucous membrane of the nostrils and bronchial tubes. Breathed in considerable quantities, it produces spitting of blood, violent pains, and sometimes death.

Medical Properties and Uses. Chlorine water is stimulant and antiseptic. Internally it has been used in typhus, and chronic affections of the liver; but the diseases in which it has been most extolled are scarlatina, malignant sore-throat, and diphtheria. Mr. Wm. M. Dobie found it more effectual in an epidemic of that disease which appeared in Chester, England, in the autumn of 1866, than any other remedy. (*Edin. Med. Journ.*, March, 1867, p. 829.) It is said, also, by Dr. Althaus, to have been used in a late epidemic of the same disease in Germany with highly satisfactory results. (*Med. Times and Gaz.*, July, 1868, p. 56.) Externally it is employed, duly diluted, as a gargle in smallpox, scarlatina, and putrid sorethroat, as a wash for ill-conditioned ulcers and cancerous sores, and as a local bath in diseases of the liver. It has been used with advantage as an application to buboes and large abscesses, to promote the absorption of the matter. As it depends upon chlorine for its activity, its medical properties coincide with those of chlorinated lime, chlorinated soda, and nitromuriatic acid, under which heads they are more particularly given. The dose of chlorine water is from one to four fluidrachms, properly diluted.

Gaseous chlorine has been recommended by Gannal in chronic bronchitis and pulmonary consumption, exhibited by inhalation, in minute quantities, four or six times a day. Its first effect is to produce some dryness of the fauces, with increased expectoration for a time, followed ultimately with diminution of the sputa and amendment. Dr. Christison states that he has repeatedly observed these results in chronic catarrh; and both he and Dr. Elliotson have obtained, in consumption, a more decided improvement of the symptoms by the use of chlorine inhalations than by any other means. The liquid in the inhaler may be formed either of water containing from ten to thirty drops of chlorine water, or of chlorinated lime dissolved in forty parts of water, to which a drop or two of sulphuric acid must be added, each time the inhalation is practised. The inhaler should be placed in water heated to about 100°. B.

AQUA CINNAMOMI. *U.S., Br. Cinnamon Water.*

"Take of Oil of Cinnamon *half a fluidrachm;* Carbonate of Magnesia *sixty*

grains; Distilled Water *two pints.* Rub the Oil first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper.

"Cinnamon Water may also be prepared by mixing *eighteen troyounces* of Cinnamon, in coarse powder, with *sixteen pints* of Water, and distilling eight pints." *U. S.*

"Take of Cinnamon Bark, bruised, *twenty ounces* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil a gallon [Imp. meas.]." *Br.*

Of these processes, the first one of the U. S. Pharmacopœia is the easier, though the second, which corresponds with the British, may yield a sweeter product. Cinnamon water is much used as a vehicle for other less agreeable medicines; but should be given cautiously in inflammatory affections. For ordinary purposes the U. S. preparation is sufficiently strong when diluted with an equal measure of water.*

Off. Prep. Mistura Cretæ; Mistura Guaiaci, *Br.;* Mistura Spiritus Vini Gallici, *Br.* W.

AQUA CREASOTI. *U. S.* *Creasote Water.*

"Take of Creasote *a fluidrachm;* Distilled Water *a pint.* Mix them, and agitate the mixture until the Creasote is dissolved." *U. S.*

This preparation contains 3·72 minims of creasote in each fluidounce, and affords a convenient method of administering that medicine. The dose is from one to four fluidrachms. It may also be used with advantage as a gargle, lotion, or mixed with cataplasms, to correct fetor, and gently stimulate indolent surfaces. W.

AQUA FŒNICULI. *U. S., Br.* *Fennel Water.*

"Take of Oil of Fennel *half a fluidrachm:* Carbonate of Magnesia *sixty grains;* Distilled Water *two pints.* Rub the Oil, first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper.

"Fennel Water may be prepared by mixing *eighteen troyounces* of Fennel, in coarse powder, with *sixteen pints* of Water, and distilling eight pints." *U. S.*

"Take of Fennel Fruit, bruised, *one pound* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

Fennel water is an agreeable vehicle for other medicines, and useful when a mild aromatic is indicated. W.

AQUA LAURO-CERASI. *Br.* *Cherry-laurel Water.*

"Take of Fresh Leaves of Common Laurel [cherry-laurel] *one pound* [avoirdupois]; Water *two pints and a half* [Imperial measure]. Chop the Leaves, crush them in a mortar, and macerate them in the Water for twenty-four hours; then distil one pint [Imp. meas.] of liquid. Shake the product, filter through paper, and preserve it in a stoppered bottle." *Br.*

As the cherry-laurel is little cultivated in the United States, we have no officinal formula for the Water; but from experiments by Prof. Procter, there is little or no room to doubt that a preparation, identical in its effects, might be made from the leaves of our common wild cherry, *Cerasus serotina,* were a demand for the medicine to spring up among us. The imported cherry-laurel water, as found in our shops, is generally more or less impaired by age, and cannot, therefore, be relied on.

The leaves yield a larger product of hydrocyanic acid when cut and bruised than when distilled whole. According to M. Garot, the proportion of the acid in cherry-laurel water depends upon the time of year at which the distillation is performed; the leaves yielding not more than half as much in April as in the middle of July. (*Annuaire de Thérap.,* 1843, p. 45.) In preparing this Water, the best plan is to thoroughly bruise the leaves, and, having mixed them with at least three times their weight of water, to allow the mixture to stand at a temperature of about 86° F. for at least twelve hours, so that opportunity may be

* In a letter to the author by Dr. E. Holmes, glycerin is recommended as an excellent intermedium between the oil of cinnamon and water. Ten drops of glycerin will effect a solution of a drop of the oil in a fluidounce of water. (*Note to the thirteenth edition.*)

given for those reactions by which the hydrocyanic acid is produced, and then to distil them by means of a current of steam. Without the preliminary maceration the distillation by steam does not afford a satisfactory result; but properly performed, it yields the largest possible product. (*Journ. de Pharm.*, Juillet, 1861, p. 15; and Juin, 1864, p. 523.) The proportion of hydrocyanic acid in the Water diminishes with time. It has been ascertained by M. Deschamps that, if a drop of sulphuric acid be added to a pint of the preparation, it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. M. Lepage found that, preserved in full and perfectly air-tight bottles, both this and bitter-almond water remained unchanged at the end of a year; while if freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (*Ibid.*, xvi. 346.) In view of the uncertain strength of the Water as obtained from the leaves, it was proposed in France, in reference to the Codex then in preparation, to fix upon a definite proportion of hydrocyanic acid; and the percentage generally adopted was from 0·04 to 0·05.* Cherry-laurel water is employed in Europe as a sedative narcotic, identical in its properties with a dilute solution of hydrocyanic acid; but it is of uncertain strength, and should not be allowed to supersede the more definite preparation of the acid now in use. Its fraudulent use in Paris in the preparation of a cordial, in imitation of the genuine cherry cordial, made by fermentation and distillation, and like it called "*kirsch*," has been the subject of no little reprobation. (*Journ. de Pharm. et de Chim.*, 4e sér., i. 33, A. D. 1865.)

The dose is from thirty minims to a fluidrachm. W.

AQUA MENTHÆ PIPERITÆ. *U. S.*, *Br.* *Peppermint Water.*

Take of Oil of Peppermint *half a fluidrachm;* Carbonate of Magnesia *sixty grains;* Distilled Water *two pints.* Rub the Oil, first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper.

* The following conclusions, in reference to Cherry-laurel water, were arrived at by a committee of pharmaceutists in Paris, appointed to examine the subject of the distilled water with a view to the revision of the Codex. 1. The whole of the volatile oil and hydrocyanic acid furnished by cherry-laurel leaves, results from a reaction between two substances analogous to the emulsin and amygdalin of bitter almonds, which can take place only in the presence of water. 2. The quantity of volatile oil furnished by the leaves is always in direct relation to that of hydrocyanic acid. 3. The leaves furnish, by mere contact for 24 hours with cold water, only one-third of the quantity which they can be made to yield. 4. The fermentable matter of the leaves is liable to change, so that the leaves, after being picked, afford less and less of the acid the longer they are kept; and a moist heat favours change; so that complete decomposition takes place in a few hours. 5. Difference in climate, soil, exposure to the sun, and age of the tree, have but a secondary influence on the productiveness of the leaves. 6. The season of the year, however, has a great influence. The younger the leaf, the greater is its yield; so that, while 0·150 per cent. of the acid was obtained from the forming leaves in spring, those of the autumn yielded 0·132, those of the winter 0·120, and leaves two years old gave only 0·112. 7. Different plants, under apparently the same circumstances, differ greatly in productiveness, so that 0·176 per cent. was obtained from the most productive, and only 0·092 from the least so. 8. The distillation by steam yields the greatest possible product. The committee, therefore, propose the adoption of this method; the bruised leaves being preliminarily mixed with at least three times their weight of water, and exposed to a gradually increasing heat, not to exceed 140° F., when all reaction ceases. 9. Bruising is the best method of comminuting the leaves. 10. As it is impossible to obtain a Water always identical from the leaves, the committee propose to fix a definite strength, and state that the proportion generally adopted is from 0·040 per cent. of acid as the minimum, to 0·050, or one-twentieth of one per cent. as the maximum, which is only one-half the strength proposed for bitter-almond water. 11. Though a change rapidly takes place in this and bitter-almond water exposed to the air, yet in bottles full, and perfectly closed by glass stoppers, the change at the end of a year is scarcely perceptible; and this observation applies to the distilled waters in general. (*Journ. de Pharm.*, Juin, 1864, p. 520.)

For some remarks as to an easy volumetric method of estimating the hydrocyanic acid strength of cherry-laurel and bitter-almond waters, as well as other liquids containing this acid, together with the figure of a simple instrument for the purpose, see a paper by Dr. W. H. Pile, in the *American Journal of Pharmacy*, March, 1862, p. 130. (*Note to the twelfth edition.*)

"Peppermint Water may also be prepared by mixing *eighteen troyounces* of Peppermint with *sixteen pints* of Water, and distilling eight pints." *U. S.*

"Take of Oil of Peppermint *one fluidrachm and a half;* Water, *one gallon and a half* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.* W.

Off. Prep. Mistura Ferri Aromatica, *Br.*

AQUA MENTHÆ VIRIDIS. *U. S., Br. Spearmint Water.*

Both in the U. S. and Br. Pharmacopœias, this is prepared precisely as Peppermint Water, the oil and herb of M. viridis being substituted in the processes for those of M. piperita.

The two mint waters are among the most grateful and most employed of this class of preparations. Together with cinnamon water, they are used in this country, almost to the exclusion of all others, as the vehicle of medicines given in the form of mixture. They serve not only to conceal or qualify the taste of other medicines, but also to counteract their nauseating properties. Peppermint water is generally thought to have a more agreeable flavour than that of spearmint, but some prefer the latter. Their effects are the same. W.

AQUA PIMENTÆ. *Br. Pimento Water.*

"Take of Pimento, bruised, *fourteen ounces* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

Pimento water is brownish when first distilled, and upon standing deposits a brown resinous sediment. It is used as a carminative in the dose of one or two fluidounces. W.

AQUA ROSÆ. *U. S., Br. Rose Water.*

"Take of Pale Rose *forty-eight troyounces;* Water *sixteen pints.* Mix them and distil eight pints.

"When it is desirable to keep the Rose for some time before distilling, it may be preserved by being well mixed with half its weight of Chloride of Sodium." *U. S.*

"Take of Fresh Petals of the Hundred-leaved Rose *ten pounds* [avoirdupois] (or an equivalent quantity of the petals preserved while fresh with common salt); Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

It should be observed that, in the nomenclature of the U. S. Pharmacopœia, the term "Rose" implies only the petals of the flower. These are usually preferred in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odour, and afford a water equally fragrant with that prepared from the fresh flower. Indeed, Mr. Haselden prefers the salted roses, believing that the water prepared from them is less mucilaginous, less apt to become sour, and preserves its odour better than that prepared from the fresh flowers. (*Pharm. Journ.*, xvi. 15.) Hence the direction for preserving them in the present U. S. Pharmacopœia. It is not uncommon to employ the whole flower including the calyx; but the product is less fragrant than when the petals only are used, as officinally directed.* Rose water is sometimes made by distilling together water and the oil of roses.

When properly prepared, it has the delightful perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the

* A. Monthus states that the petals of the hundred-leaved rose are more odorous the nearer they are to the centre of the flower, and, contrary to what is said in the text, thinks that the calyx should not be rejected in preparing the distilled water. He maintains that so far from injuring the product, it in fact contributes to its preservation, and that the water obtained from the whole flower is less liable to that mucosity, which is the commencement of decomposition. This effect he ascribes to the astringent matter of the calyx, which coagulates the mucilaginous matter of the petals, and thus prevents it from passing over in the distillation. (*Journ. de Pharm.*, Dec. 1863, p. 497.)—*Note to the twelfth edition.*

water is applied, and is even said to render it sour through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. This distilled water is chiefly employed, on account of its agreeable odour, in collyria and other lotions. It is wholly destitute of irritating properties, unless when it contains alcohol.*

Off. Prep. Confectio Rosæ, *U. S.*: Mistura Ferri Composita; Trochisci Bismuthi, *Br.*; Unguentum Aquæ Rosæ, *U. S.* W.

AQUA SAMBUCI. *Br. Elder-flower Water.*

"Take of Fresh Elder Flowers, separated from the stalks, *ten pounds* [avoirdupois] (or an equivalent quantity of the flowers preserved while fresh with common salt); Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

Elder flowers yield very little oil upon distillation; and, if the water be needed, it may be best prepared from the flowers. Mr. Haselden prefers the salted flowers to the fresh, for the reason stated under Rose Water. The preparation is little used in this country. W.

ARGENTUM.

Preparations of Silver.

ARGENTI CYANIDUM. *U. S.* Argenti Cyanuretum. *U. S.* 1850. *Cyanide of Silver. Cyanuret of Silver.*

"Take of Nitrate of Silver, Ferrocyanide of Potassium, each, *two troyounces*; Sulphuric Acid *a troyounce and a half*; Distilled Water *a sufficient quantity*. Dissolve the Nitrate of Silver in a pint of Distilled Water, and pour the solution into a tubulated glass receiver. Dissolve the Ferrocyanide of Potassium in ten fluidounces of Distilled Water, and pour the solution into a tubulated retort, previously adapted to the receiver. Having mixed the Sulphuric Acid with four fluidounces of Distilled Water, add the mixture to the solution in the retort, and distil, by means of a sand-bath, with a moderate heat, until six fluidounces have passed over, or until the distillate no longer produces a precipitate in the receiver. Lastly, wash the precipitate with Distilled Water, and dry it." *U. S.*

This preparation was introduced into the U. S. Pharmacopœia for the purpose of being used in the extemporaneous preparation of diluted hydrocyanic acid. (See *page* 960.) By the formula adopted in the Pharmacopœia of 1840, the officinal hydrocyanic acid was added to a solution of nitrate of silver. The expenditure in this way of the officinal acid, which is very weak, and at the same time nicely adjusted to a given strength, was injudiciously directed; and, accordingly, that formula was abandoned, and a new process adopted in the Pharmacopœia of 1850, and continued in the present, in which all the silver contained in a given weight of nitrate of silver, placed in a receiver in solution, is converted into cyanide by hydrocyanic acid, extricated from ferrocyanide of potassium by the action of sulphuric acid. By a double decomposition between the oxide of silver of the nitrate and the hydrocyanic acid, water and cyanide of silver are formed in the receiver, the latter of which precipitates. The materials in the retort are sufficient to produce a little more hydrocyanic acid than is necessary to convert the whole of the silver in the receiver into cyanide; so that the complete decomposition of the nitrate of silver is ensured.

According to Messrs. Glassford and Napier, the best way of obtaining cyanide of silver is to add cyanide of potassium to a solution of nitrate of silver so long as a precipitate is formed.

* *Artificial Rose Water.* Prof. Wagner, of Germany, prepares a distilled water from the *oil of gaultheria*, with an odour so closely resembling that of the rose as to be entitled to this designation. He boils the oil with solution of potassa, thereby obtaining salicylate of potassa, the mother-liquor of which, when distilled with water, yields the preparation in question. (*Chem. Gaz.*, no. 382, p. 352; from *Wagner's Jahresbericht*, A. D. 1856, p. 260.)—*Note to the twelfth edition.*

Properties. Cyanide of silver is a tasteless white powder, insoluble in water and cold nitric acid, but readily soluble, with decomposition, in that acid when boiling hot. It is decomposed by muriatic acid, exhaling the odour of hydrocyanic acid. It is not soluble in potassa or soda, but readily so in ammonia. Its best solvent is cyanide of potassium. When heated it is decomposed, cyanogen being evolved, and metallic silver left. It consists of one eq. of cyanogen 26, and one of silver 108=134. It has no medical uses.

Off. Prep. Acidum Hydrocyanicum Dilutum, *U. S.* B.

ARGENTI NITRAS. *U. S.*, *Br.* *Nitrate of Silver. Nitrate of Silver in Crystals.*

"Take of Silver, in small pieces, *two troyounces;* Nitric Acid *two troyounces and a half;* Distilled Water *a sufficient quantity.* Mix the Acid with a fluidounce of Distilled Water in a porcelain capsule, add the Silver to the mixture, cover it with an inverted glass funnel, resting within the edge of the capsule, and apply a gentle heat until the metal is dissolved, and red vapours cease to be produced; then remove the funnel, and, increasing the heat, evaporate the solution to dryness. Melt the dry mass, and continue the heat, stirring constantly with a glass rod, until free nitric acid is entirely dissipated. Dissolve the melted salt, when cold, in six fluidounces of Distilled Water, allow the insoluble matter to subside, and decant the clear solution. Mix the residue with a fluidounce of Distilled Water, filter through paper, and, having added the filtrate to the decanted solution, evaporate the liquid until a pellicle begins to form, and set it aside in a warm place to crystallize. Lastly, drain the crystals in a glass funnel until dry, and preserve them in a well-stopped bottle. By evaporating the mother-water, more crystals may be obtained." *U. S.*

"Take of Purified Silver *three ounces* [avoirdupois]; Nitric Acid *two and a half fluidounces* [Imperial measure]; Distilled Water *five fluidounces* [Imp. meas.]. Add the Nitric Acid and the Water to the Silver in a flask, and apply a gentle heat till the metal is dissolved. Decant the clear liquor from any black powder which may be present, into a porcelain dish, evaporate, and set aside to crystallise; pour off the clear liquor, and again evaporate and crystallise. Let the crystals drain in a glass funnel, and dry them by exposure to the air, carefully avoiding the contact of all organic substances. Nitrate of Silver must be preserved in bottles furnished with accurately ground stoppers." *Br.*

The two formulas are essentially the same; but that of the U. S. Pharmacopœia is more detailed and precise, with two peculiarities which deserve notice. One of these is the direction to cover the materials in the capsule, during the continuance of the reaction, with a glass funnel. This is in order to economize the nitric acid, a portion of which rises in vapour, and, being condensed on the inner surface of the funnel, falls again into the capsule. The second peculiarity is the fusion of the salt before being dissolved. This would, from the phraseology of the directions, appear to have been intended to get rid of any uncombined nitric acid which might remain in the dry salt. But the effect is probably rather to decompose any nitrate of copper that might have been derived from the silver, which, if coin be employed, always contains it. This accounts for the escape of hyponitric acid vapour. The oxide of copper is got rid of in the subsequent solution.

During the solution of silver in nitric acid, part of the acid is decomposed into nitric oxide which is given off and becomes red fumes by contact with the atmosphere, and oxygen which oxidizes the silver. The oxide formed then combines with the remainder of the acid, and generates the nitrate of silver in solution, which, by due evaporation, furnishes crystals of the salt. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both muriatic and sulphuric acids, should

never be used in this process. The muriatic acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble sulphate of silver.*

Properties. Nitrate of silver is in colourless transparent shining crystals, having the form of rhomboidal plates, sometimes of considerable size. Its taste is bitter and intensely metallic. It is soluble in its own weight of cold water, and in four parts of boiling alcohol. When perfectly pure, it is wholly soluble in distilled water. The solution stains the skin of an indelible black colour, and is itself discoloured by the most minute portion of organic matter, of which it forms a delicate test. The affinity of this salt for animal matter is evinced by its forming definite compounds with albumen and fibrin. The solution also stains linen and muslin in a similar manner; and hence its use in making the so-called indelible ink. To remove these stains, Mr. W. B. Herapath advises to let fall on the moistened spots a few drops of tincture of iodine, which converts the silver into iodide of silver. The iodide is then dissolved by a solution of hyposulphite of soda, made with half a drachm to a fluidounce of water, or by a moderately dilute solution of caustic potassa, and the spots are washed out with warm water. They are taken out also by a solution of two and a half drachms of cyanide of potassium, and fifteen grains of iodine, in three fluidounces of water. Stains on the skin may be removed by the same reagents. Nitrate of silver melts at 426°, and on concreting forms the fused nitrate, which is officinal under the name of *Argenti Nitras Fusa.* At about 600° it is decomposed, with evolution of oxygen and hyponitric acid, and the metal is revived. This explains the necessity of guarding against too high a heat during the fusion of the salt. Nitrate of silver is incompatible with almost all spring and river water, on account of a little common salt usually contained in it; with soluble chlorides; with sulphuric, hydrosulphuric, muriatic, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime-water; and with astringent infusions. It is sometimes improperly prescribed in pill with tannic acid, by which it is decomposed. Nitrate of silver is an anhydrous salt, consisting of one eq. of nitric acid 54, and one of protoxide of silver $116 = 170$ (AgO,NO_5).

Impurities and Tests. Muriatic acid or a solution of chloride of sodium, added in excess to one of nitrate of silver, should throw down the whole of the silver as a white curdy precipitate darkening on exposure to light, and nothing besides. This precipitate should be entirely soluble in ammonia. If not so, the insoluble part is probably chloride of lead. If the supernatant liquid, after the removal of the precipitate, be discoloured or precipitated by sulphuretted hydrogen, the fact shows the presence of metallic matter, which is probably copper or some remains of lead, or both. The solution, after precipitation by muriatic acid and filtration, should leave no residue when evaporated. A piece of the salt, heated on charcoal by the blowpipe, melts, deflagrates, and leaves behind a whitish metallic coating. After all, the best sign of the purity of nitrate of silver is the characteristic appearance of the crystals. For other tests, see *Argenti Nitras Fusa.*

Medical Properties. Nitrate of silver, as an internal remedy, is deemed tonic and antispasmodic. The principal diseases in which it has been employed are epilepsy, chorea, angina pectoris, and other spasmodic affections. In epilepsy it forms our most reliable remedy; but the kind of cases to which it is particularly applicable, and its modus operandi, are not understood. It is said to produce most good in this disease when it acts upon the bowels. Wunderlich has found it specially useful in the affection named progressive locomotor ataxia (*Ann. de Thérap.*, 1863, p. 210); and cases of general progressive paralysis are said by M. E. Bouchut to have been cured by it. M. Bouchut recommends it also in the

* It is desirable that pure silver, free from copper, should be used in this process. As silver coin always contains copper, it should be purified before being employed. For this purpose, according to the method of M. Lienau, it should be dissolved in nitric acid, and the solution precipitated by chlorine water, which throws down the silver only in the form of chloride. The precipitate is to be well washed with chlorine water, then dissolved in solution of ammonia, and precipitated by clean copper wire. The silver is deposited as a black powder, which, when washed with solution of ammonia, is perfectly pure. (See *Am. Journ. of Pharm.*, July, 1862, p. 368.)

palsy of the insane. (*Ann. de Thérap.*, 1866, p. 273.) It is among our most efficient remedies in chronic gastritis, attended with pain and vomiting. Dr. J. F. Peebles, of Petersburg, Va., bore testimony to its efficacy in jaundice connected with gastric irritation, given preferably on an empty stomach. (*Am. Journ. of the Med. Sciences*, July, 1849.) Dr. Boudin, of Marseilles, employed it in typhoid fever as a remedy for the inflammation and ulceration of the ileum, which constitute the most constant lesion in that disease. M. Delioux, of Rochefort, has proposed albuminous injections of nitrate of silver in diarrhœa, formed of half a pint of water, containing the white of one egg, from two to four grains of the nitrate, and an equal weight of common salt. Nitrate of silver is soluble in an excess of an albuminous solution, and when thus prepared is more readily absorbed than when dissolved in water. The common salt promotes its solution without decomposing it. (*Journ. de Pharm.*, xx. 149.) In chronic diarrhœa, especially in that kind attendant on phthisis, Dr. Macgreggor, of Dublin, has found the nitrate of silver, conjoined with opium, a valuable remedy. It has also been used with supposed advantage in cholera infantum, in doses varying from one-sixteenth to one-fourth of a grain, at intervals of two, four, or six hours. Whatever may be the remedial value of this salt internally administered, its occasional effect of producing a slate-coloured discoloration of the skin, which is seldom removed, is a great objection to its use. This effect proves the absorption of the medicine, and is stated to show itself first on the tongue and fauces. According to Dr. Branson, an indication of the approach of discoloration is furnished by the occurrence of a dark-blue line on the edges of the gums, very similar to that produced by lead, but somewhat darker. For this discoloration of the skin a steady course of cream of tartar has been recommended.

Externally, nitrate of silver is occasionally employed in solution as a stimulant and escharotic; but the *fused nitrate*, which is not so pure as the officinal *nitrate* (pure salt in crystals), is generally selected for making solutions. In cases requiring nicety, the officinal nitrate (crystals) should be directed to be dissolved, and distilled water should be selected as the solvent. A solution, made in the proportion of half a grain of the crystals to a fluidounce of distilled water, forms a good mouth-wash for healing ulcers produced by mercury. In the inflammation of the mouth from mercurial salivation, M. Bouchacourt found a concentrated solution of the salt, applied to the gums, base of the tongue, &c., with a camel's-hair brush, very useful. A solution, containing from two to ten grains of the crystals to a fluidounce of distilled water, is an excellent application in ophthalmia with ulcers of the cornea, in fetid discharges from the ear, aphthous affections of the mouth, and spongy gums.

The dose of nitrate of silver (crystals) is the fourth of a grain, gradually increased to four or five grains, three times a day. For internal exhibition, the physician should always prescribe the crystals, which are meant by the name Argenti Nitras in the revised nomenclature of the U. S. Pharmacopœia of 1850, and never direct the fused nitrate (Argenti Nitras Fusa), which is often impure. Nitrate of silver should always be given in pill, in which form, according to Dr. Powell, the system bears a dose three times as large as when given in solution. In the treatment of epilepsy, this physician recommends the exhibition at first of grain doses, to be gradually increased to six grains, three times a day. Its effects vary very much, owing no doubt to the salt being more or less decomposed by the substances used in preparing it in pill, or with which it comes in contact in the stomach. It should not be made up into pill with crumb of bread, as this contains common salt, but with some vegetable powder and mucilage. But, as all organic substances more or less decompose it, M. Vée proposes the use of inorganic matter, such as nitre, or preferably pure silica obtained by precipitating one of the silicates by an acid, and washing it. The least possible proportion of tragacanth may be used to give adhesiveness to the mass. (*Journ. de Pharm.*, Mai, 1864, p. 408.) In view of the fact that chloride of sodium is used with food, and exists, together with phosphates, in the secretions, and that

free muriatic acid and albuminous fluids are present in the stomach, it is almost certain that, sooner or later, the whole of the nitrate of silver will be converted into the chloride, phosphate, and albuminate, compounds far less active than the original salt. The experiments of Keller, who analyzed the feces of patients under the use of this salt, confirm this view. Such being the inevitable result when the nitrate is given, the question arises how far it would be expedient to anticipate the change, and give the silver as a chloride ready formed. One of the authors of this work has tried the chloride in large doses, in two cases of epilepsy, but without advantage. According to Mialhe, nitrate of silver upon entering the stomach is immediately changed into the chloride, and this is quickly converted into a soluble and readily absorbable double chloride, by combining with chloride of sodium or of potassium.

Nitrate of silver, in an overdose, produces the effects of the corrosive poisons. The proper antidote is common salt, which acts by converting the poison into the insoluble chloride of silver.

Off. Prep. Argenti Cyanidum, *U. S.;* Argenti Nitras Fusa, *U. S.;* Argenti Oxidum. B.

ARGENTI NITRAS FUSA. *U.S.* Argenti Nitras. *Br.* Lapis Infernalis. *Fused Nitrate of Silver. Lunar Caustic.*

"Take of Nitrate of Silver *a convenient quantity.* Melt it in a porcelain capsule, and continue the heat cautiously until frothing ceases; then pour the melted salt into suitable silver moulds." *U. S.*

"To obtain the Nitrate in rods, fuse the crystals in a capsule of platinum or thin porcelain, and pour the melted salt into proper moulds." *Br.*

Instead of forming the nitrate of silver, as in the process of 1850, the present U. S. Pharmacopœia takes the salt already formed, and simply melts it with certain precautions. The British process is merely the continuation of that by which the nitrate is obtained in crystals. As the salt while melting sinks into a common crucible, the fusion is performed in one of porcelain or platinum, the size of which should be sufficient to hold five or six times the quantity of the salt operated on, in order to prevent its overflowing in consequence of the ebullition. Sometimes small portions of the liquid are spirted out, and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should be warmed, but not greased, as organic matter would thus be furnished, which would partially decompose the fused salt.*

Properties. Fused nitrate of silver, as prepared by the above process, is in the form of hard brittle sticks, of the size of a goose quill, at first translucent, but quickly becoming gray or more or less dark under the influence of light, owing to the reduction of the silver, effected probably by organic matter, or sulphuretted hydrogen contained in the atmosphere. That the change does not depend on the sole action of light has been proved by Mr. Scanlan, who finds that nitrate of silver, in a clean glass tube hermetically sealed, undergoes no change by exposure to light. The sticks often become dark-coloured and nearly black on the surface, and, when broken across, exhibit a crystalline fracture with a radiated surface. Fused nitrate of silver, when pure, is wholly soluble in distilled water; but even fair samples of the fused salt will not totally dissolve, a very scanty black powder being left of reduced silver, arising probably from the salt having been exposed to too high a heat in fusion.

Impurities and Tests. Fused nitrate of silver is liable to contain free silver from having been exposed to too high a heat, the nitrates of lead and copper

* For certain purposes it is desirable to have the nitrate of silver less brittle than in its pure state. Prof. J. L. Smith, of Louisville, Ky., has found that this may be effected by adding a little chloride of silver, which renders the stick tough, without materially impairing its efficiency. Dr. Squibb proposes to accomplish the object by adding 40 grains of muriatic acid, with half a fluidounce of distilled water, to two ounces of nitrate of silver, heating the mixture by means of a sand-bath to dryness, and then melting and casting into moulds. (*Proceedings of the Am. Pharm. Assoc.*, 1858.)—*Note to the twelfth edition.*

from the impurity of the silver dissolved in the acid, and nitrate of potassa from fraudulent admixture. Free silver will be left undissolved as a black powder, after the action of distilled water. A very slight residue of this kind is hardly avoidable; but, if there be much free silver, it will be shown by the surface of a fresh fracture of one of the sticks presenting an unusually dark-gray colour. (*Christison.*) The mode of detecting lead and copper is explained under nitrate of silver. (See *Argenti Nitras.*) In order to detect nitre, a solution of the suspected salt should be treated with muriatic acid in excess, to remove silver, and with sulphuretted hydrogen, to throw down other metals if they happen to be present. The filtered liquid, if the salt be pure, will entirely evaporate by heat; if it contain nitre, this will be left, easily known by its properties as a nitrate. This impurity sometimes exists in fused nitrate of silver in large amount, varying, according to different statements, from 10 to 75 per cent. According to Dr. Christison, it may be suspected if the sticks present a colourless fracture. In the Br. Pharmacopœia the following method is given for testing fused nitrate of silver for impurity, without determining its nature. "Ten grains dissolved in two fluidrachms of distilled water give with hydrochloric acid a precipitate, which, when washed and thoroughly dried, weighs 8·44 grains. The filtrate when evaporated by a water-bath leaves no residue." If the weight of the precipitate be greater or less than here stated, there must be some impurity in the nitrate; and any non-precipitable matter, if solid at the temperature of the water-bath, will be left behind when the filtrate is evaporated. In the U. S Pharmacopœia, the following test, suggested by Dr. Squibb, is given to detect nitre or other saline impurity. "A small portion, rubbed into fine powder with twice its weight of sugar, forms a mixture, which, when burned upon a surface of glass or porcelain, leaves a tasteless residue." If the nitrate is pure, only the reduced metal is left, which is without taste. If it contain only as much as 1 per cent. of nitre, or other saline impurity, the residue will have the sharp alkaline taste of the base of the salt. (*Am. Journ. of Pharm.*, Jan. 1859, p. 50.)

Medical Properties. Fused nitrate of silver should be restricted to external use. The medical properties of the salt, as an internal remedy, are given under the head of the *crystallized* nitrate (See *Argenti Nitras.*) Externally applied the fused nitrate acts variously as a stimulant, vesicant, and escharotic, and may be employed either dissolved in water, or in the solid state. Dissolved to the extent of from one to five grains in a fluidounce of water, it is used for the purpose of stimulating indolent ulcers, and as an injection for fistulous sores. A drachm of the fused salt, dissolved in a fluidounce of water, forms an escharotic solution, which may often be resorted to with advantage. When used in solution it is most conveniently applied by means of a camel's-hair brush. But fused nitrate of silver is most frequently employed in the solid state; and, as it is not deliquescent nor apt to spread, it forms the most manageable caustic that can be used. When thus employed, it is useful to coat the caustic, as recommended by M. Dumeril, by dipping it into melted engravers' sealing-wax, which strengthens the stick, protects it from change, prevents it from staining the fingers, and affords facilities for limiting the action of the caustic to particular spots. If it is desired, for example, to touch a part of the throat with the caustic, it is prepared by scraping off the sealing-wax with a penknife, to a suitable extent from one end. Another way to strengthen the stick is to cast it around a platinum wire, as recommended by M. Chassaignac; or around a wick of cotton, according to the plan of M. Blatin. By the latter plan, when the stick is broken, the fragments remain attached. If the fused nitrate be rubbed gently over the moistened skin until this becomes gray, it generally vesicates, causing usually less pain than is produced by cantharides. The fused nitrate is also employed to destroy strictures of the urethra, warts and excrescences, fungous flesh, incipient chancres, and the surface of other ulcers. Mr. Higginbottom considers its free application to ulcers, so as to cover them with an eschar, as an excellent means of expediting their cicatrization. He alleges that, if an adherent eschar be formed, the parts underneath heal before it falls off. It has also been used with

good effect in the solid state, by Dr. Jewell in leucorrhœa, and by Ricord, Hannay, and others in the gonorrhœa of women. In these cases the pain produced is much less than would be expected. Lunar caustic is frequently used in aqueous solution as a topical remedy in various low forms of inflammation, but particularly in erysipelas, applied both to the inflamed and to the surrounding healthy parts. In some cases it is sufficient to blacken the cuticle; in others it is best to produce vesication. In the treatment of these inflammations, Mr. Ward, of London, finds an ethereal solution, formed by dissolving eight grains of the salt in a fluidounce of common nitric ether, much more convenient and manageable than an aqueous solution. The ethereal solution is readily applied, and quickly dries. The late Dr. J. Wiltbank, of this city, used an aqueous solution of nitrate of silver (from 20 to 40 grains to the fluidounce) in the treatment of superficial burns and scalds, applied with a camel's-hair brush over the whole surface, first wiped dry, after opening the vesications. If the burn be deep, the entire surface of the ulcer should be touched with the stick. (*Med. Exam.*, March, 1856, p. 144.) In cases of prolapsus ani, Mr. Lloyd, of London, smears the whole surface of the protruded bowel with the solid caustic, and then returns it. Three or four applications, at intervals of a week or fortnight, are generally sufficient to effect a cure. Mr. Lloyd never knew this practice to be attended with bad consequences. Prof. Parker, of New York, uses nitrate of silver for the radical cure of hydrocele. After drawing off the liquid, he introduces, through the cannula, a common probe, the end of which is coated, for half an inch or more, with the caustic. The probe is then carried lightly over the serous surface of the tunica vaginalis, and withdrawn. In smallpox it has been proposed by Bretonneau and Serres to cauterize each pustule, after its top has been removed, on the first or second day of the eruption, in order to arrest its development, and prevent pitting. The fused nitrate also forms an efficacious application to certain ulcerations of the throat, to different forms of porrigo of the scalp, and other skin diseases, to punctured and poisoned wounds, and to chilblains, slowly rubbed over the moistened part. If, unexpectedly, the pain produced by its external use should be excessive, it may be immediately allayed by washing the parts with a solution of common salt, which acts by decomposing the caustic. In the form of ointment, made by mixing one part of the caustic, in powder, with thirty of lard, it has been used in ozæna; a piece of lint, smeared with the ointment, being introduced into the nasal fossa.

Nitrate of silver, in impalpable powder, mixed with an equal weight of lycopodium, and used by inhalation, has been found beneficial in ulcerated sore-throat, laryngitis, bronchitis, and incipient phthisis, by Dr. W. M. Cornell, of Boston. (*Boston Med. and Surg. Journ.*, Sept. 25, 1850.) The salt, used in this way, has since been successfully employed in the treatment of chronic laryngitis by M. Trousseau, of Paris, and others. The mixture employed consisted of three grains of the nitrate and a drachm of sugar of milk, intimately mixed in fine powder, of which as much as would fill the barrel of a steel pen was inhaled daily. The steel pen, charged with the powder, and attached to the barrel of a quill, is placed on the root of the tongue, and the patient compresses his lips around the quill. Then holding his nose, he makes a deep inspiration, which draws the powder into the larynx. (See *Am. Journ. of Med. Sci.*, Oct. 1855, p. 515.) This plan of applying nitrate of silver to the larynx is much more sure and safe than that of introducing the solution by injection, or by means of a sponge. Dr. Guillon, of France, strongly recommends the insufflation of the powder in pseudomembranous croup, having derived great advantage from it in his own experience. (*South. Med. and Surg. Journ.*, March, 1867, p. 486; from *Revue de Thérap.*) The solution may often be applied to different parts of the throat by means of the atomizer. B.

ARGENTI OXIDUM. *U. S., Br. Oxide of Silver.*

"Take of Nitrate of Silver *four troyounces;* Distilled Water *half a pint;* Solution of Potassa *a pint and a half*, or *a sufficient quantity.* Dissolve the Nitrate of Silver in the Water, and to the solution add Solution of Potassa so

long as it produces a precipitate. Wash this repeatedly with water until the washings are nearly tasteless. Lastly, dry the precipitate and keep it in a well-stopped bottle, protected from the light." *U. S.*

"Take of Nitrate of Silver, in crystals, *half an ounce* [avoirdupois]; Solution of Lime *three pints and a half* [Imperial measure]; Distilled Water *ten fluidounces*. Dissolve the Nitrate of Silver in four [fluid]ounces of the Distilled Water, and, having poured the solution into a bottle containing the Solution of Lime, shake the mixture well, and set it aside to allow the deposit to settle. Draw off the supernatant liquid, collect the deposit on a filter, wash it with the remainder of the Distilled Water, and dry it at a heat not exceeding 212°. Keep it in a stoppered bottle." *Br.*

Oxide of silver was introduced into the U. S. Pharmacopœia of 1850, and was adopted in the Br. Pharmacopœia from the Dublin. In the processes for making it, nitrate of oxide of silver is decomposed by potassa or lime, the oxide being precipitated, and nitrate of potassa or nitrate of lime, as the case may be, remaining in solution. When thus obtained the oxide is an olive-brown powder. If the potassa used be not wholly free from carbonic acid, the precipitated oxide will be contaminated with some carbonate of silver. According to Mr. Borland, of London, the carbonate is sometimes sold for the oxide. A third process for obtaining this oxide is that of Gregory, which consists in boiling the moist, recently prepared chloride of silver with a very strong solution of caustic potassa (sp. gr. 1·25 to 1·30). In this case, by double decomposition, oxide of silver and chloride of potassium are formed. When thus prepared it is a very dense pure black powder. Oxide of silver is very slightly soluble in water. Exposed to heat it gives out oxygen, and is wholly converted into metallic silver; 29 grains of it yielding 27 of the metal. (*Br.*) It should not effervesce with acids. When its solution in nitric acid is precipitated by chloride of sodium in excess, the supernatant liquid is not discoloured by bihydrosulphate of ammonia. The non-action of this test shows the absence of most foreign metals, especially copper and lead. It parts with its oxygen with great facility, being decomposed by many organic substances, and even causing sulphur to take fire when the two are rubbed together, quite dry, in a mortar. (*Chem. News*, May 7, 1864, p. 217.) Oxide of silver consists of one eq. of silver 108, and one of oxygen 8=116.

Medical Properties. This oxide has been proposed as a substitute for nitrate of silver, as having the general therapeutic virtues of the latter, without its escharotic effect, and objectionable property of discolouring the skin. It was first tried as a medicine by Van Mons and Sementini. In 1840 it was employed by Dr. Butler Lane, who considered it to act as a sedative. In 1845 the late Sir James Eyre strongly recommended it in his work on exhausting diseases. Dr Lane used it with more or less success in nausea, cardialgia, pyrosis, various painful affections of the stomach without organic lesion, dysentery, diarrhœa, night-sweats without other obvious affection, dysmenorrhœa, menorrhagia, leucorrhœa, chronic enlargements of the uterus attended with flooding, &c. The oxide appeared to exert a peculiar control over uterine fluxes. Some of the cases treated required the use of tonics, after the curative influence of the oxide had been exerted. The late Dr. Golding Bird also obtained favourable effects from the use of oxide of silver, and confirmed to a certain extent the results of Dr. Lane, especially as to its valuable powers in menorrhagia. Thus far no case of cutaneous discoloration is known to have occurred; though Dr. Lane gave the oxide repeatedly for two months, and Dr. Bird in more than a hundred cases, in one for four months. Dr. Lane observed one case in which repeated salivation occurred, and Dr. Bird several in which the gums were affected. But, in order to draw any inference from these results, the prescriber should be certain that the medicine is not contaminated with black oxide of mercury. In stomach disease, characterized by a glairy instead of a watery discharge, Dr. Bird derived not the slightest benefit from the oxide, though he used it in thirty cases. In epilepsy it is supposed by some that the oxide will accomplish all that can be expected from the nitrate, with less risk to the stomach, and without incur-

ring the danger of discolouring the skin. In tænia it has been used successfully in two cases by Mr. Whittel. The dose of oxide of silver is a grain, twice or thrice a day, given in pill. In no case did Dr. Lane carry the dose beyond six grains in the twenty-four hours. The pill should not be made with honey, conserve of roses, or other excipient containing glucose; and, indeed, most organic substances, especially in a moist state, deoxidize the oxide, reviving the silver. Mr. Ambrose Smith recommends, as among the best excipients, gum arabic, or this with a little syrup. (*Proceed. of Am. Pharm. Assoc.*, 1859, p. 308.) Oxide of silver has been used in the form of ointment, composed of from five to ten grains to the drachm of lard, as an application to venereal sores, and to the urethral membrane in gonorrhœa, smeared on a bougie. B.

ARSENICUM.

Preparation of Arsenic.

The officinal liquid preparations of arsenic are, in compliance with the Pharmacopœias, considered under the head of *Liquores* or *Solutions*. (See *Liquor Arsenici et Hydrargyri Iodidi, Liquor Potassæ Arsenitis*, and *Liquor Sodæ Arsenitis*, in *Part* II.) It is only the Iodide of Arsenic that is treated of in this place.

ARSENICI IODIDUM. *U.S. Iodide of Arsenic.*

"Take of Arsenic *sixty grains;* Iodine *three hundred grains*. Rub the Arsenic in a mortar until reduced to a fine powder; then add the Iodine, and rub them together until they are thoroughly mixed. Put the mixture into a small flask or a test-tube, loosely stopped, and heat it very gently until liquefaction occurs. Then incline the vessel in different directions, in order that any portion of the iodine, which may have condensed on its surface, may be returned into the melted mass. Lastly, pour the melted iodide on a porcelain slab, and, when it is cold, break it into pieces, and keep it in a well-stopped bottle." *U. S.*

This iodide was introduced into the U. S. Pharmacopœia for the purpose of being used in preparing the solution of iodide of arsenic and mercury. It is made by the direct combination of its constituents, with the aid of a gentle heat.

Properties, &c. Iodide of arsenic is an orange-red, crystalline solid, entirely soluble in water, and wholly volatilized by heat. In composition it is considered to be a *teriodide*, consisting of one eq. of arsenic 75, and three of iodine $378{\cdot}9 = 453{\cdot}9$. It has been used by Biett as an external application in corroding tubercular skin diseases. By the late Dr. A. T. Thomson it was given internally with advantage in lepra, impetigo, and diseases resembling cancer. Dr. F. C. Crane cured a case of what he considered cancer of the breast by its use for nearly eight months. The ointment used by Biett was composed of three grains of the iodide to an ounce of lard. The dose for internal exhibition is an eighth of a grain three times a day, given in pill or solution.

Off. Prep. Liquor Arsenici et Hydrargyri Iodidi, *U. S.* B.

ATROPIA.

Preparations of Atropia.

ATROPIA. *U.S., Br. Atropia.*

"Take of Belladonna Root, in fine powder, *forty-eight troyounces;* Purified Chloroform *four troyounces and a half;* Diluted Sulphuric Acid, Solution of Potassa, Alcohol, Water, each, *a sufficient quantity*. Mix the powder with a pint of Alcohol, and, having introduced the mixture into a cylindrical percolator, pour alcohol gradually upon it until six pints have passed. From the liquid, thus obtained, distil off twelve pints of alcohol. To the residue add sufficient Diluted Sulphuric Acid to give it an acid reaction, and, having evaporated the liquid to half a pint, add an equal bulk of Water, and filter through paper. To the filtered liquid add, first a troyounce and a half of the Chloro-

form, and then Solution of Potassa in slight excess, and shake the whole together at intervals, for half an hour. When the heavier liquid has subsided, separate it, and, having added a troyounce and a half of the Chloroform to the lighter liquid, again shake them together, and separate the heavier from the lighter liquid as before. Add to this lighter liquid the remainder of the Chloroform, and, after agitation, separate the heavier liquid for the third time. Mix the heavier liquids in a capsule, and set the mixture aside until, by spontaneous evaporation, the Atropia is left dry." *U. S.*

"Take of Belladonna Root, recently dried and in coarse powder, *two pounds* [avoirdupois]; Rectified Spirit *ten pints* [Imperial measure]; Slaked Lime *one ounce* [avoird.]; Dilute Sulphuric Acid, Carbonate of Potash, of each, *a sufficiency;* Chloroform, *three fluidounces;* Purified Animal Charcoal, *a sufficiency;* Distilled Water *ten fluidounces.* Macerate the Root in four pints [Imp. meas.] of the Spirit, for twenty-four hours, with frequent stirring. Transfer to a displacement apparatus, and exhaust the root with the remainder of the Spirit by slow percolation. Add the Lime to the tincture placed in a bottle, and shake them occasionally several times. Filter, add the Dilute Sulphuric Acid in very feeble excess to the filtrate, and filter again. Distil off three-fourths of the Spirit, add to the residue the Distilled Water, evaporate at a gentle heat, but as rapidly as possible, until the liquor is reduced to one-third of its volume and no longer smells of alcohol; then let it cool. Add very cautiously, with constant stirring, a solution of the Carbonate of Potash so as nearly to neutralise the acid, care, however, being taken that an excess is not used. Set to rest for six hours, then filter, and add Carbonate of Potash in such quantity that the liquid shall acquire a decided alkaline reaction. Place it in a bottle with the Chloroform; mix well by frequently repeated brisk agitation, and pour the mixed liquids into a funnel furnished with a glass stop-cock. When the Chloroform has subsided, draw it off by the stop-cock, and distil it on a water-bath from a retort connected with a condenser. Dissolve the residue in warm Rectified Spirit; digest the solution with a little Animal Charcoal; filter, evaporate, and cool until colourless crystals are obtained." *Br.*

The U. S. process is a modification of the one proposed by Prof. Procter in a communication to the American Pharmaceutical Association, published in their *Proceedings* for the year 1860. The root is first exhausted by alcohol, by means of percolation, a large proportion of the alcohol is distilled off, and sulphuric acid is added in slight excess, so as to convert the atropia into the sulphate, and thus enable it to be held in solution in the next step of the process. The liquid is now further concentrated, so as to separate nearly all the alcohol, and then mixed with water to separate resinous and fatty matters. The sulphate of atropia is left in solution. This, after filtration, is treated with chloroform and solution of potassa in slight excess, the latter to separate the atropia from the sulphate, and the former to dissolve it when thus separated; and the repeated agitation with the chloroform is in order that the whole of the atropia may be dissolved. Chloroform is admirably adapted to this purpose, at once by its insolubility in water, and by its extraordinary solvent power over atropia, of which it is capable of taking up 33 per cent. The chloroformic solution sinks to the bottom in consequence of its density, and, having been separated, yields the atropia by spontaneous evaporation. The alkaloid as thus obtained is not pure, still containing resinous and colouring matters; but it was deemed sufficiently so for medical use. This we think unfortunate; for it is impossible, unless the alkaloid be obtained pure or very nearly so, to determine, in any particular instance, unless by a complicated operation, the precise amount of impurity, and consequently the precise strength of the preparation. Had it been deemed advisable to follow the process of Mr. Procter, in all its steps, this result might have been avoided. Though atropia is very soluble in chloroform, the sulphate of that alkaloid is insoluble. Consequently, if the impure solution of the sulphate left after the precipitation of the resinous matter by water, be thoroughly agitated, as suggested by Mr. Procter, with a portion of chloroform, it is deprived of most of

its remaining resinous, fatty, and colouring matters, still retaining the alkaloid in the form of sulphate, which, after the removal of the chloroform, it will yield in a comparatively pure state to the subsequent treatment by solution of potassa and chloroform. Though caustic potassa is believed to decompose atropia by prolonged contact, yet, in this instance, its opportunity for any injurious action would be too fugitive to justify apprehension on this score; for it speedily becomes neutralized by the sulphuric acid, while the liberated alkaloid is as quickly seized by the chloroform, and carried out of its sphere of action. But, even with this improvement of the process, the alkaloid, as yielded by the spontaneous evaporation, is not quite free from impurity, and, to be obtained entirely pure and colourless, should be dissolved in alcohol, treated with a little animal charcoal, and then allowed to crystallize by the spontaneous evaporation of the alcoholic solution after filtration. Prof. Procter obtained only about one-third of 1 per cent. of pure atropia from the amount of root used. The use of chloroform as a solvent of atropia, in preparing that alkaloid, was, we believe, first suggested by M. Rabourdin, of Orleans, in France. The application of it to the purification of the impure sulphate originated with Prof. Procter. As chloroform is too valuable to be lost when it can conveniently be saved, it would be advisable, when it is used in this process, instead of allowing it to escape by spontaneous evaporation, to recover it by distillation with a warm-bath, taking care, by using a temperature not exceeding 160° F., to shun any danger of decomposing the atropia.

The British process, as will be seen by comparing it with the notes below, is a combination of the processes of Mein and Rabourdin, the former being followed until after the addition of carbonate of potassa, and the alkaloid thus liberated being taken up by chloroform as in the latter. The use of lime in the earlier stage of the proceedings is to cause a precipitation of various substances which would otherwise embarrass the subsequent operations.*

* The following is the process employed by Mein for procuring atropia. The roots of plants two or three years old were selected. Of these, in extremely fine powder, 24 parts were digested, for several days, with 60 parts of alcohol of 86 or 90 per cent. The liquid having been separated by strong expression, the residue was treated anew with an equal quantity of alcohol; and the tinctures, poured together and filtered, were mixed with one part of hydrate of lime, and frequently shaken for 24 hours. The copious precipitate which now formed was separated by filtering; and diluted sulphuric acid was added drop by drop to the filtered liquor, till slightly in excess. The sulphate of lime having been separated by a new filtration, the alcoholic liquid was distilled to one-half, then mixed with 6 or 8 parts of pure water, and evaporated with a gentle heat till the whole of the alcohol was driven off. The residual liquid was filtered, cautiously evaporated to one-third, and allowed to cool. A concentrated aqueous solution of carbonate of potassa was then gradually added, so long as the liquid continued to be rendered turbid; and the mixture was afterwards suffered to rest some hours. A yellowish resinous substance, which opposes the crystallization of the atropia, was thus precipitated. From this the liquid was carefully decanted, and a small additional quantity of the solution of the carbonate was dropped into it, till it no longer became turbid. A gelatinous mass now gradually formed, which, at the end of 12 or 24 hours, was agitated in order to separate the mother-waters, then thrown upon a filter, and dried by folds of unsized paper. The substance thus obtained, which was atropia in an impure state, was dissolved in five times its weight of alcohol; and the solution, having been filtered, was mixed with six or eight times its bulk of water. The liquor soon became milky, or was made so by evaporating the excess of alcohol, and, in the course of 12 or 24 hours, deposited the atropia in the form of light-yellow crystals, which were rendered entirely pure and colourless by washing with a few drops of water, drying on blotting-paper, and again treating with alcohol. From 12 oz. of the root, Mein obtained 20 grs. of the alkaloid. (*Journ. de Pharm.*, xx. 87.)

M. Rabourdin, of Orleans, in France, prepares atropia by means of chloroform in the following manner. To each litre (about 2 pints) of the expressed juice of the fresh leaves, deprived of its albumen by heat and filtration, or to a filtered solution of 60 grammes (about 15 drachms) of extract in 200 grammes of distilled water, 4 grammes of potassa, and 30 grammes of chloroform are added, the whole is shaken for a minute, and then set aside. In half an hour, the chloroform, holding the atropia in solution, is seen at the bottom of the vessel, resembling a greenish oil. The supernatant liquor is decanted, and small portions of water successively added and removed, until no longer rendered turbid. The chloroformic solution is then distilled, by means of a salt-water bath, until all the chloroform has passed. The residue is treated with a little water acidulated with sulphuric acid, which dissolves the atropia, leaving a green resinous matter. The solution is then

Properties. Atropia is in silky, prismatic, acicular crystals, which, when quite pure, are colourless, but, as obtained according to our officinal formula, are yellowish-white. It is inodorous, but has a bitter and acrid taste. It is said to melt at 194° F., and at 284° to be volatilized, a portion being unchanged, but the greater part destroyed. According to Dr. Guy, it melts at 150°, and sublimes at 280° (*Pharm. Journ.*, Feb. 1868, p. 374); and, according to Mr. Waddington, the liquid remains perfectly colourless, and the vapour condenses in perfect crystals; showing that the alkaloid does not undergo decomposition at its subliming point. (*Ibid.*, March, 1868, p. 416.) It is inflammable, giving off an odour like that of benzoic acid, and, when burned in the open air, leaving no residue. By distilling it with bichromate of potassa and sulphuric acid, Dr. E. Pfeiffer succeeded in obtaining crystals of benzoic acid. (*Am. J. of Pharm.*, May, 1864, p. 226.) Dr. Kraut, by heating it with baryta-water, succeeded in obtaining an uncrystallizable salt, consisting of a peculiar acid and peculiar base, the former of which he calls *atropic acid* and the latter *tropia*. (*Ibid.*, p. 232.) It is said, moreover, that when a little of it, dissolved in a few drops of sulphuric acid, is heated, an odour is given out resembling that of orange flowers. (*Ibid.*, March, 1864, p. 112.) It is soluble in 300 parts of water at 60°, in 8 parts of alcohol (*Geiger and Hesse*), in 25 parts of ether, in 50 parts of glycerin (*Cap and Garot*), and, according to Schlimpert, in a little more than 3 parts of chloroform; and in all these liquids it is more soluble hot than cold. It has a strong alkaline reaction, forms crystallizable salts with acids, and, in solution, gives a lemon-yellow precipitate with terchloride of gold. Heated with potassa or soda it gives out ammonia, and is rendered inert by prolonged contact with the former alkalies. Hinterberger states that an alcoholic solution of atropia, when cyanogen is passed through it, assumes a blood-red colour, and, on spontaneous evaporation, deposits a red syrupy liquid insoluble in water. (*Gmelin.*) In very dilute solution, the alkaloid produces, when applied to the eye, a speedy and durable dilatation of the pupil. Its composition is represented by the formula $C_{34}H_{23}NO_6$.

Medical Properties and Uses. The effects of atropia on the system are precisely those of belladonna, whether locally or generally, whether in moderate doses as a remedy, or in excessive quantities as a poison. It is in general, however, somewhat more speedy in its operation, probably in consequence of its easier absorption. Thus, the poisonous action of belladonna is seldom experienced in less than half an hour, while that of atropia shows itself violently in fifteen or twenty minutes. The most prominent effects from the smallest remedial doses are dryness and stricture of the throat, and slight uneasiness of the head, with confusion or giddiness; from somewhat larger doses, dilatation of the pupil, some dimness of vision, frontal headache, slight delirium, flushed face, and sometimes a scarlet rash; from poisonous doses, the above symptoms in a more aggravated form, great dimness or total temporary loss of vision, excessive dilatation of the pupil, intense headache or violent delirium followed by stupor, paralytic sensations, intense redness of the face, neck, &c., at first acceleration but afterwards depression of the pulse, and finally great prostration, profound coma, coldness of the extremities, and death, if relief is not obtained. Sometimes nausea and vomiting are produced, and occasionally diarrhœa. There is often an increased disposition to micturate; and atropia has been detected in the urine

filtered, the atropia precipitated by carbonate of potassa in slight excess, and the precipitate dissolved in rectified alcohol, which, upon evaporation, yields it in beautiful groups of needles. (*Gaz. Méd. de Paris*, Oct. 19, 1850.)

Mr. W. T. Luxton obtains atropia by adding a little sulphuric acid to a strong decoction of the leaves so as to precipitate the albumen, filtering, and either passing gaseous ammonia through the clear liquor, or suspending in it a lump of carbonate of ammonia. Atropia slowly crystallizes, and in a day or two may be separated on a filter, and deprived of colour by washing with spirit of ammonia. Mr. Luxton obtained between 5 and 6 grains from 1000 of the leaves. (See *Am. Journ. of Pharm.*, xxvii. 156.)

An account of the effects of numerous reagents upon the muriate of atropia, by Dr. A. Von Planta, may be found in the *American Journal of Pharmacy* (xxiii. 38).

of those who have taken it freely. In a case recorded by Dr. James Andrew two-thirds of a grain occasioned the most alarming symptoms, which continued for several days (*Ed. Month. Journ. of Med. Sci.*, xiv. 34); and a lady, under the care of M. Roux, of Brignolles, took somewhat more than a grain, with the same alarming symptoms (*Ann. de Thérap.*, 1861, p. 14); though, in both cases, recovery took place under treatment. In a child of three years old less than half a grain was followed by similar dangerous symptoms, and the same favourable result. (*Med Times and Gaz.*, Dec. 1850, p. 601.) A solution of atropia dropped into the eye produces dilatation of the pupil after ten or fifteen minutes, without causing congestion or inflammation; and the dilatation will usually continue for two or three days. Sometimes it is said that the dilatation is followed by contraction of the pupil, especially when the dose is large. The alkaloid also produces its characteristic constitutional effects when applied to the skin denuded of the epidermis, or to a mucous membrane, as of the rectum, vagina, &c., and especially when injected into the subcutaneous areolar tissue. The remedies for its poisonous operation are the same as those for belladonna; the most prominent being evacuation of the stomach, cold applications to the head, the preparations of opium internally,* and stimulants when the strength is failing. The officinal compound solution of iodine has been given in poisoning by atropia, and with apparent advantage, in one or two cases, though other remedies were employed at the same time. It acts by forming an insoluble compound with the alkaloid. (See *Belladonna.*)

Atropia may be used internally for all the purposes for which belladonna is given; but it is chiefly as a local remedy, for application to the eye, or to the surface of the body, or for subcutaneous injection that it is preferred; and for these purposes it has the advantage over the ordinary preparations of belladonna, of greater precision of dose, quicker action, and greater neatness and cleanliness. The dose to begin with, for internal use, is about one-thirtieth of a grain, which may be gradually increased till some effect is experienced; but it is almost too powerful for prudent employment in this way, especially as all the effects of belladonna may be readily obtained from the extract. Dr. Sieveking found, in a trial upon himself, that one-hundredth of a grain produced brief vertigo followed by dryness of the throat, without affection of the viscera, but with nervous depression next day. (*B. and F. Med.-chir. Rev.*, July, 1858, Am. ed., p. 179.) It may be administered dissolved in diluted alcohol, in the proportion of two grains to half a fluidounce, of which four minims, or twice the number of drops, may be given for a commencing dose. If given in pill, the greatest care should be taken to distribute the atropia equally in the pill-mass before dividing it. For application to the eye, one grain may be dissolved in four fluidrachms of distilled water by means of a few drops of acetic acid, of which no more should be used than is necessary to effect the solution. Of this, a single drop, applied to the inner surface of the lower lid, will produce dilatation of the pupil in 15 or 20

* In reference to the relative effects of atropia and morphia, hypodermically administered, Drs. S. Weir Mitchell, Keen, and Morehouse have come to the following conclusions, among others, from a series of experiments and observations. Atropia has no power to relieve pain, while morphia acts powerfully, and the more so the nearer it is to the seat of pain; and atropia has no power of diminishing the action of morphia in this respect. Morphia lowers the pulse slightly if at all, while atropia usually lowers it within ten minutes, then accelerates it from twenty to fifty beats within an hour, followed about the tenth hour by a reduction, and within twenty-four hours by a return to the normal state; and morphia has no power to prevent the effect of atropia on the pulse. With the change of the pulse, the respiration is hardly in any degree affected. As regards the eye, the two alkaloids are mutually antagonistic; but the action of atropia is much more durable. The cerebral symptoms produced by the one alkaloid are to a great extent capable of being superseded by the other; but in consequence of the difference in their speed of action, and the longer continued action of the atropia, it is difficult to obtain a perfect neutralization of effect. The dry mouth of atropia is not lessened by morphia. Atropia does not constipate like morphia, and may even relax the bowels. The nausea of morphia is not prevented or removed by atropia. Both alkaloids occasionally cause dysuria, and that caused by one is not relieved by the other. (*Am Journ. of Pharm.*, Sept. 1865, p. 389.)—*Note to the thirteenth edition.*

minutes. The same solution may be used for subcutaneous injection in the quantity of 8 or 10 drops to commence with, and gradually increased. Mr. T. P. Teale, of Leeds, has obtained the happiest results in the treatment of iritis by the application of a solution of atropia to the eye. It is often alone adequate to the cure. (*Am. Journ. of Med. Sci.*, July, 1867, p. 265.) For application to the sound skin, the form of ointment is most convenient. This may be made by rubbing a grain of the alkaloid first with four minims of alcohol, and then with a drachm of lard. Glycerin and olein also have been recommended as vehicles of atropia for external use; and may be incorporated with it in the same proportion.

When solution of atropia is used locally for dilating the pupil, it may be either dropped into the eye within the lower lid, or may be introduced on small slips of paper previously saturated with the solution and dried, or, what is still more convenient, by means of minute circular discs of gelatin, made by mixing the solution with gelatin and evaporating so as to procure a thin film, which is to be cut into circular pieces. These have the advantage over paper that they do not require to be subsequently removed from the eye.

The external use of atropia is not without danger, unless great caution be observed. A case is on record in which an ointment composed of three grains of the sulphate and two drachms of lard, applied upon a vesicated surface on the neck, produced in a few minutes the most violent symptoms of belladonna poisoning, ending in death in two hours. (*Ann. de Thérap.*, 1867, p. 9.)

Off. Prep. Atropiæ Sulphas; Liquor Atropiæ, *Br.*; Unguentum Atropiæ, *Br.* W.

ATROPIÆ SULPHAS. *U. S.*, *Br.* *Sulphate of Atropia.*

"Take of Atropia *sixty grains;* Stronger Ether *four fluidounces and a half;* Sulphuric Acid *six grains;* Stronger Alcohol *a fluidrachm.* Dissolve the Atropia in the Ether; then mix the Acid and Alcohol, and add the mixture, drop by drop, to the ethereal solution until the Atropia is saturated. Allow the liquid to stand until the precipitate formed is deposited. Then decant the ether, and expose the residue to spontaneous evaporation until the salt is dry." *U. S.*

"Take of Atropia *one hundred and twenty grains;* Distilled Water *four fluidrachms;* Diluted Sulphuric Acid *a sufficiency.* Mix the Atropia with the Water and add the Acid gradually, stirring them together until the alkaloid is dissolved, and the solution is neutral. Evaporate it to dryness at a temperature not exceeding 100°." *Br.*

The U. S. is essentially the process of M. Ch. Maitre, which is contained in a note in the 11th edition of the Dispensatory. Atropia being soluble in ether while its sulphate is insoluble in that fluid, a convenient method is afforded for preparing the sulphate with little evaporation. By adding the mixed acid and alcohol to the ethereal solution, the sulphate is formed, and being insoluble in the ether is deposited; while the little left dissolved in the alcohol is obtained by spontaneous evaporation. The quantity of acid added is intended to saturate the alkaloid; but if the saturation should not be exact, it would be easy to render it so by the addition of a little more of the alkaloid or a little more of the acid, as the case may be.

From the great facility with which atropia undergoes change, much caution is necessary in preparing its salts; and the process was arranged in reference to this caution. Upon the addition of the mixed acid and alcohol to the ethereal solution, the liquid becomes milky, and deposits on the sides of the vessel a copious precipitate, of a viscid appearance, which soon dries upon the decantation of the ether, and the placing of the vessel in a drying room. To succeed with this process, it is necessary that the liquids employed should be carefully freed from water, the sulphuric acid being monohydrated, and that the temperature should be kept as low as possible. There should be no excess of acid; and, if such an excess should be found upon applying the test of litmus paper, the solution should be neutralized by a portion of reserved solution of atropia. (*Am. Journ. of Pharm.*, xxviii. 361; from *Répert. de Pharm.*) In the British

process the same object of avoiding decomposition by heat is arrived at by the low temperature at which the evaporation is effected.

Sulphate of atropia, as thus obtained, is a white slightly crystalline powder, having the taste of atropia, very soluble in water and alcohol, but insoluble in ether and chloroform. It should be dissipated by heat, and neutral to test-paper. It is known to be a sulphate by giving a white precipitate, with chloride of barium, and a salt of atropia by its effect in dilating the pupil, when a drop of a weak solution is introduced into the eye.

If it be required to procure the sulphate in the form of crystals, which may sometimes be desirable to avoid adulteration, the process of M. Laneau may be employed. A solution of crystallized atropia in absolute alcohol, in the proportion of 2·89 parts of the former to 4 parts of the latter by weight, having been made with the assistance of a gentle heat, 0·4 parts of sulphuric acid of the sp. gr. 1·85, diluted with 3 parts of absolute alcohol, are to be gradually added, and stirred with a glass rod, until saturation, as shown by test-paper, is effected. The solution is then allowed to evaporate spontaneously, and the thinner the stratum the sooner will the process be completed. The crystals are in colourless needles more or less interlaced. (See *Am. Journ. of Pharm.*, July, 1863, p. 315.)

The effects of the salt on the system are precisely the same as those of atropia, and it may be used in the same dose. Its only advantage over the alkaloid is its solubility in water. The sulphate is recommended by Dr. Fleming, associated in very small doses with sulphate of magnesia, and aromatic sulphuric acid, in habitual constipation. (*Ann. de Thérap.*, 1867, p. 4.) A solution of the salt in the proportion of one part to one hundred of the solvent has been found instantaneously efficacious in the relief of toothache, applied in the quantity of a drop or two to the denuded dental pulp; and it is said, in the same quantity, to produce complete insensibility of the dental nerves, in cases in which an artifi cial tooth is inserted in a living root. (*Ann. de Thérap.*, 1861, p. 19.)* W.

BARIUM.

Preparation of Barium.

BARII CHLORIDUM. *U.S. Chloride of Barium. Muriate of Baryta.*

"Take of Carbonate of Baryta, in small pieces, Muriatic Acid, each, *four troyounces;* Water *a pint.* Mix the Acid with the Water, and gradually add the Carbonate of Baryta. Towards the close of the effervescence apply a gentle heat, and, when chemical action has ceased, filter the liquid, and evaporate so that crystals may form when it cools." *U. S.*

When carbonate of baryta is employed for obtaining chloride of barium, as in the officinal process, the reactions are very simple. The muriatic acid displaces the carbonic acid with effervescence; and, by reacting with the baryta, forms

* *Valerianate of Atropia.* This salt has been supposed to have peculiar virtues; though, in consideration of the very minute proportion of the valerianic acid in each dose, it is extremely doubtful whether it is capable, in any appreciable degree, of modifying the influence of the alkaloid. It may be prepared by dissolving 38 parts of pure and dry atropia in 140 parts of alcohol of 85°, and mixing the solution with another made by dissolving 12 parts of pure valerianic acid in 10 parts of alcohol of the same strength; and allowing the mixed liquids to evaporate spontaneously at a heat of from 86° to 100° F. (*Journ. de Pharm.*, Mars, 1864, p. 236.) According to M. Michéa, the valerianate of atropia produces the effects of this alkaloid in smaller doses than the sulphate or even atropia itself. He has often known half a milligramme (about $\frac{1}{130}$ gr.) to produce dryness of the throat and dilatation of the pupils the day after its exhibition, while it is generally not till the expiration of several days that he had been able to obtain the same effect from double the dose of the sulphate given daily. He also found less of the valerianate required than of the sulphate to modify the paroxysms of epilepsy. (*Ann. de Thérap.*, 1864, p. 31.) In the *Journal de Pharmacie* for Nov. 1858 (p. 347) there is a particular account of the chemical properties and mode of procuring of valerianate of atropia in the crystalline form, to which the reader is referred. It is probable that, as in the case of valerianate of ammonia, less difficulty will be found, if our officinal monohydrated valerianic acid is employed. (*Note to the twelfth edition.*)

chloride of barium and water. The solution of chloride of barium, thus obtained, yields crystals of the chloride by concentration and cooling. Another plan is that which procures it from the sulphate, as directed in the late Edinburgh Pharmacopœia. In this the sulphate, previously ignited and powdered, is mixed with charcoal and exposed to a low white heat, by which its constituents are deoxidized, and sulphuret of barium produced; the oxygen escaping in combination with the carbon as carbonic oxide and acid. The sulphuret of barium, after having been dissolved in water, is decomposed by the addition of muriatic acid; sulphuretted hydrogen being evolved, and chloride of barium formed in solution, from which, in the usual manner, the solid salt is obtained.

Of these processes, that in which the native carbonate is used is the simplest and most convenient; but the carbonate is comparatively a rare mineral, and, as the sulphate in fine powder is a cheap article of commerce, being extensively employed for mixing with white lead, it is almost always used for obtaining chloride of barium and the other barium compounds.

Properties. Chloride of barium is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with beveled edges. It dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 222°, the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol, impregnated with it, burns with a yellow flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates, and tartrates, and the alkaline phosphates, borates, and carbonates; also by nitrate of silver, acetate and phosphate of mercury, and acetate of lead. When pure it does not deliquesce. Its solution is not affected by ammonia, which proves the absence of alumina and sesquioxide of iron, or by sulphuretted hydrogen, which shows that neither copper nor lead is present. After the whole of the barium has been precipitated by an excess of sulphuric acid, the supernatant liquid is shown to be free from lime by the non-action of carbonate of soda. Lime may be separated by the process of Dr. Wolcott Gibbs, which consists in adding to the solution of the chloride a small portion of the solution of hydrate of baryta, and then passing through it a current of carbonic acid, when the whole of the lime will be thrown down as a carbonate. (Wurtz, *N. Y. Journ. of Pharm.*, i. 164.) If strontia be present, an alcoholic solution of the salt will burn with a red flame. Like all the soluble salts of barium it is poisonous. It consists of one eq. of chlorine 35·5, one of barium 68·7, and two of water 18 = 122·2. It is used in medicine only in solution. The officinal solution, Liquor Barii Chloridi, is treated of among the LIQUORES, or *Solutions*.

Off. Prep. Liquor Barii Chloridi, *U. S.* B.

BEBERIA.

Preparation of Bebeeria.

BEBERIÆ SULPHAS. *Br. Sulphate of Bebeeria.*

"Take of Bebeeru Bark [Nectandra, *U. S.*], in coarse powder, *one pound* [avoirdupois]; Sulphuric Acid *half a fluidounce* [Imperial measure]; Slaked Lime *three-quarters of an ounce*, or *a sufficiency;* Solution of Ammonia *a sufficiency;* Rectified Spirit *sixteen fluidounces*, or *a sufficiency;* Diluted Sulphuric Acid *a sufficiency;* Water *one gallon* [Imp. meas.]; Distilled Water *a sufficiency*. Add the Sulphuric Acid to the Water; pour upon the Bark enough of this mixture to moisten it thoroughly; let it macerate for twenty-four hours, place it in a percolator, and pass through it the remainder of the acidulated water. Concentrate the acid liquor to the bulk of one pint, cool, and add gradually the Lime in the form of milk of lime, agitating well, and taking care that the fluid still retains a distinct acid reaction. Let it rest for two hours; filter through calico; wash the precipitate with a little cold Distilled Water, and to the filtrate add Solution of Ammonia until the fluid has a faint ammoniacal

odour. Collect the precipitate on a cloth, wash it twice with ten ounces of cold water, squeeze it gently with the hand, and dry it by the heat of a water-bath. Pulverise the dry precipitate, put it into a flask with six ounces of the Rectified Spirit, boil, let it rest for a few minutes, and pour off the spirit. Treat the undissolved portion in a similar manner with fresh spirit until it is exhausted. Unite the spirituous solutions, add to them four ounces of Distilled Water, and distil so as to recover the greater part of the spirit. To the residue of the distillation add by degrees, and with constant stirring, Diluted Sulphuric Acid till the fluid has a slight acid reaction. Evaporate the whole to complete dryness on the water-bath, pulverise the dry product, pour on it gradually one pint [Imp. meas.] of cold Distilled Water, stirring diligently; filter through paper; evaporate the filtrate to the consistence of syrup, spread it in thin layers on flat porcelain or glass plates, and dry it at a heat not exceeding 140°. Preserve the product in stoppered bottles." *Br.*

This was a new officinal of the first British Pharmacopœia, scarcely deserving the prominence thus given to it from anything yet known of its powers, especially when it is considered how unsparingly not a few of the older remedies, still thought by many practitioners to be efficacious, were swept out of the officinal catalogue.

In the above process the bark is exhausted by water acidulated with sulphuric acid; lime is added to separate various inert matters, still leaving the acid in excess, as otherwise it might precipitate the bebeeria itself; the filtered liquor is treated with ammonia which throws down the bebeeria; the precipitate is exhausted by alcohol which dissolves the alkaloid; and the solution, having been concentrated, is treated with sulphuric acid so as to form the sulphate, which is obtained by evaporation to dryness. It is obvious that the salt of bebeeria thus obtained must be very impure, and among other substances probably contains a portion of sipeeria, another alkaloid of the bark. It is in dark-brown translucent scales, yellow when reduced to powder, of a strongly bitter taste, and soluble in water and alcohol. According to the Br. Pharmacopœia, "its watery solution gives with chloride of barium a white precipitate, and with caustic soda a yellowish-white precipitate, which is dissolved by agitating the mixture with twice its volume of ether; and the ethereal solution, separated by a pipette, and evaporated, leaves a yellow translucent residue, entirely soluble in diluted acids." If the whole of the precipitate produced is dissolved by ether, it cannot contain sipeeria, which is insoluble in that menstruum. It is "entirely destructible by heat, and water forms with it a clear brown solution."

Sulphate of bebeeria is a tonic, supposed to possess antiperiodic powers, and has been given in intermittent fever and other periodical diseases. It is thought to be useful also in various uterine diseases, as dysmenorrhœa, menorrhagia, and leucorrhœa; and has been recommended in blenorrhœal discharges, and in atony of the kidneys and bladder. (Dr. A. P. Merrill, *Half-yearly Abstract of Med. Sci.*, xlv. 249.) The dose is from two to five grains. (See *Nectandra*, in *Part* I.)

W.

BISMUTHUM.

Preparations of Bismuth.

BISMUTHI SUBCARBONAS. *U. S.* Bismuthi Carbonas. *Br.* *Subcarbonate of Bismuth. Carbonate of Bismuth.*

"Take of Bismuth, in pieces, *two troyounces;* Nitric Acid *eight troyounces and a half;* Water of Ammonia *five fluidounces;* Carbonate of Soda *ten troyounces;* Distilled Water *a sufficient quantity.* Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled Water in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, after twenty-four hours, filter through paper. To the filtered liquid, previously diluted with four pints of Distilled Water, slowly add the Water of Ammonia, with constant stirring. Transfer the whole to a strainer,

and, after the precipitate has been drained, wash it with two pints of Distilled Water, drain it again, and press out as much of the liquid as possible. Then place the precipitate in a proper vessel, add the remainder of the Nitric Acid, and heat nearly to the boiling point. When the solution has become cold, slowly add to it Distilled Water, with constant stirring, until the further addition of this liquid begins to produce a permanent milkiness. Then set the solution aside, and, at the end of twenty-four hours, filter through paper.

"Dissolve the Carbonate of Soda in twenty fluidounces of Distilled Water, with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless. Lastly, press the precipitate so as to free it as far as possible from water, dry it on bibulous paper with a gentle heat, and rub it into powder." *U. S.*

"Take of Purified Bismuth, in small pieces, *two ounces* [avoirdupois]; Nitric Acid *four fluidounces* [Imperial measure]; Carbonate of Ammonia *six ounces* [avoird.]; Distilled Water *a sufficiency.* Mix the Nitric Acid with three [fluid]ounces [Imp. meas.] of Distilled Water, and add the Bismuth in successive portions. When effervescence has ceased, apply for ten minutes a heat approaching that of ebullition, and afterwards decant the solution from any insoluble matter that may be present. Evaporate the solution until it is reduced to two fluidounces [Imp. meas.], and add this in small quantities at a time to a cold filtered solution of the Carbonate of Ammonia in two pints [Imp. meas.] of Distilled Water, constantly stirring the mixture as it is formed. Collect the precipitate on a calico filter, and wash it with Distilled Water until the washings pass tasteless. Remove now as much of the adhering water as can be separated from the precipitate by slight pressure with the hands, and finally dry the product at a temperature not exceeding 150°." *Br.*

This preparation was first made officinal in the existing edition of the U. S. Pharmacopœia. As metallic bismuth generally contains arsenic, it is very important to provide that this should be left behind, in the processes for making its medicinal preparations. It is on this account that the present formula is so elaborate. The bismuth is first dissolved in nitric acid, a portion of which oxidizes the metal, with the evolution of nitrous vapours, while another portion combines with the oxide produced to form nitrate of bismuth. At the same time the arsenic is also oxidized at the expense of the nitric acid, and unites with a portion of the oxidized metal so as to generate the arseniate of bismuth. Both of these salts, therefore, are contained in the solution, which is very concentrated. Both have the property, when their solution is diluted with water, to separate into two salts, one an insoluble subsalt which is deposited, and the other a soluble supersalt which is held in solution. But the arseniate is more disposed to the change than the nitrate, and requires for the purpose a smaller amount of water of dilution. Hence, the first direction, after the metal has been dissolved, is to add a moderate quantity of distilled water, insufficient to cause the decomposition of the nitrate. From this diluted solution the insoluble subarseniate is slowly deposited, so as, in the course of twenty-four hours, to free it almost if not entirely from the poisonous metal. This is separated by filtration, and the solution is now diluted with a much larger quantity of distilled water, which causes a copious deposition of subnitrate of bismuth. But, in order not to waste the supernitrate remaining in solution, this is decomposed by ammonia, which takes most of the nitric acid, and precipitates the bismuth combined with the remainder in the form of subnitrate. The whole of the precipitated subnitrate, thus freed from arsenic, is redissolved in nitric acid, and the solution of the nitrate now obtained, being diluted with just so much water as to produce a commencing precipitation of subnitrate, is freed by filtering from the small quantity formed, and slowly added to a solution of carbonate of soda. An interchange of principles takes place; nitrate of soda and carbonate of bismuth are formed, the former of which remains in solution, and the latter is deposited. This part of the process tends

still further to get rid of the arsenic; for if any of the arsenic acid or arseniate of bismuth exist in the solution, the poisonous acid would combine with the soda, and thus forming a soluble salt, would be retained by the water. Nothing now remains but to wash, dry, and powder the precipitate.

The British process is more simple, because, using bismuth already purified, it is without the preliminary measures taken in the U. S. process to separate the arsenic. It is essentially the same as the method described in the twelfth edition of this Dispensatory (*page* 1025); carbonate of ammonia being used instead of carbonate of soda for the precipitation of the subcarbonate of bismuth.

Properties. Subcarbonate of bismuth is a white or yellowish-white powder, blackened by sulphuretted hydrogen, without odour or taste, and insoluble in water, whether pure or impregnated with carbonic acid. (*Berzelius.*) Its sp. gr. is about 4. It effervesces with acids, and, when exposed to heat, loses 9·5 per cent. of its weight (*U. S.*), in consequence of the escape of carbonic acid, and is converted into the anhydrous teroxide, of a light-yellow colour. When mixed with sulphuric acid, and subjected to Marsh's test, it should yield no arsenic, or merely a trace. "The nitric acid solution gives no precipitate with diluted sulphuric acid or with solution of nitrate of silver. If to nitric acid mixed with half its volume of distilled water as much carbonate of bismuth be added as the acid will dissolve, one volume of this solution poured into twenty volumes of water will yield a white precipitate." *Br.* If arsenic were present, a precipitate would take place with a much smaller proportion of water. The formula of the subcarbonate is BiO_3,CO_2, or, according to the Br. Pharmacopœia, $2(BiO_3,CO_2),HO$.

Medical Properties and Uses. This salt was brought into notice by M. Hannon, of Brussels, who recommends it as a substitute for the subnitrate. He considers it to act for the first few days of its employment as a sedative, and afterwards as a tonic. Like the subnitrate it is applicable to the treatment of gastralgia following the phlegmasias of the digestive organs, and attended with a red tongue, laborious digestion, acid eructations, and spasmodic vomitings. He conceives it, however, to have many advantages over the subnitrate, among which are its more ready tolerance by the stomach, its greater solubility in the gastric juice, its power to neutralize excess of acid in the stomach, and the want of any tendency to constipate. The dose is from 15 to 45 grains, given three times a day just before meals, and gradually increased. It may be taken in a little water. (*Ann. de Thérap.*, 1857, p. 214.) W.

BISMUTHI SUBNITRAS. *U. S.* BISMUTHUM ALBUM. *Br. Subnitrate of Bismuth. White Bismuth.*

"Take of Bismuth, in pieces, *two troyounces;* Nitric Acid, Carbonate of Soda, each, *ten troyounces;* Water of Ammonia *six fluidounces;* Distilled Water *a sufficient quantity.* Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled Water, in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, at the end of twenty-four hours, filter through paper.

"Dissolve the Carbonate of Soda in twenty fluidounces of Distilled Water with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless, and drain again as completely as possible. Then place the moist precipitate in a capacious vessel, gradually add the remainder of the Nitric Acid, and heat nearly to the boiling point. When the solution has become cold, slowly add to it Distilled Water, with constant stirring, until the further addition of this liquid begins to produce a permanent milkiness. Then set the solution aside, and, at the end of twenty-four hours, filter through paper. To the filtered liquid, previously diluted with four pints of Distilled Water, slowly add the Water of Ammonia, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been

drained, wash it with two pints of Distilled Water, drain it again, and press out as much of the liquid as possible. Lastly, dry it upon bibulous paper with a gentle heat, and rub it into powder." *U. S.*

"Take of Bismuth, in small pieces, *two ounces* [avoirdupois]; Nitric Acid *four fluidounces* [Imperial measure]; Distilled Water *a sufficiency*. Mix the Nitric Acid with three [fluid]ounces of Distilled Water, and add the Bismuth in successive portions. When effervescence has ceased, apply for ten minutes a heat approaching that of ebullition, and decant the solution from any insoluble matter that may be present. Evaporate the solution until it is reduced to two fluidounces, and pour it into half a gallon of Distilled Water. When the precipitate which forms has subsided, decant the supernatant liquid, add half a gallon [Imp. meas.] of Distilled Water to the precipitate, stir them well together, and after two hours, decant off the liquid, collect and drain the precipitate in a calico filter, press it with the hands, and dry it at a temperature of 150°." *Br.*

The U. S. process is new, the British that of the late Dublin Pharmacopœia. The alterations from the old process, in the former, were based upon the wish to get rid of any arsenic that might be present in the bismuth used. This is accomplished by first preparing the carbonate, by adding the nitric acid solution of bismuth to a solution of carbonate of soda in excess, whereby most of the arsenic is retained in the solution probably as arseniate of soda, while the insoluble carbonate is precipitated. This is dissolved, with the aid of heat, in nitric acid, so as to make a very concentrated solution of the nitrate, to which, when cold, just so much water is added as to begin to produce a permanent turbidness. The object of this is to allow any arsenic that may be still present to be deposited, which happens for reasons stated in explaining the process for procuring the subcarbonate. (See *page* 1063.) The deposited matter having been precipitated, only the pure nitrate remains in solution, which is made to yield the subnitrate by large dilution with water, and still more completely by the addition of ammonia.

In the British formula, the old method is pursued of simply dissolving the bismuth, which has been previously purified, in nitric acid somewhat diluted, concentrating the solution, and precipitating by adding it to a large quantity of water. When bismuth is added to dilute nitric acid, red fumes are copiously given off, and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder so as to form a solution of the ternitrate of teroxide of bismuth. It is unnecessary to have the metal in powder; as it dissolves with great facility when added to the acid in fragments. When the solution is completed, the liquor should be added to the water, and not the water to the solution. Immediately on the contact of the solution with the water, four eqs. of the ternitrate are resolved into three eqs. of mononitrate of bismuth (subnitrate) which precipitates, and one eq. of the 9-nitrate which remains in solution. $4(BiO_3,3NO_5)=3(BiO_3,NO_5)$ and $BiO_3,9NO_5$. In order to have a smooth light powder, which is most esteemed, the precipitate should be well washed to remove every trace of free nitric acid, and dried as speedily as possible. In the use of this formula it is taken for granted that the bismuth has been ascertained to be free from arsenic; and, if it prove upon the application of Marsh's test to be otherwise, means should certainly be employed to purify before using it. Measures for this purpose will be mentioned under Bismuthum Purificatum (*page* 1067). Should the subnitrate or subcarbonate be ascertained to contain arsenic, it may, as suggested by Dr. Herapath, be purified by boiling it with solution of caustic soda or potassa, twice successively, then thoroughly washing the residue, which will be yellow oxide of bismuth, dissolving it again in nitric acid, and precipitating by water as before. (*Chem. News*, Feb. 14, 1863, p. 77.) In the washing of subnitrate of bismuth, the salt is asserted to lose a portion of its nitric acid; and the change may be considerable, if the washing be persevered with so long as the liquid comes away in any degree acidulous. It has been ascertained by Julius Löwe that this effect may be avoided by washing with a very dilute solution of nitrate of ammonia, containing one part in 500 parts of water. (*Chem. Gaz.*, March 15, 1859, p. 119.)

Properties. Subnitrate of bismuth is a heavy powder, of a pure-white colour, a faintly sour smell and taste, and the property of reddening moistened litmus paper. It is slightly soluble in water, and readily so in the strong acids, from which it is precipitated by water. The fixed alkalies dissolve it sparingly, and ammonia more readily. It is darkened by hydrosulphuric acid gas, but not by exposure to light, unless it contains a little silver, or is subjected to the influence of organic matter. If it dissolves in nitric acid without effervescence, it contains no carbonate, and, if the nitric solution is not precipitated by dilute sulphuric acid, it is free from lead. It sometimes contains arsenic, which may be detected by acting on it with pure sulphuric acid, evaporating to dryness, dissolving in hot distilled water, and testing a part of the solution by Marsh's apparatus. By this method M. Lassaigne detected one-sixth of 1 per cent. of arsenic in a sample of subnitrate sold in Paris. M. Glénard proposes two new methods of searching for arsenic in the subnitrate; one merely qualitative, the other quantitative. The first consists in strongly heating a mixture of the suspected salt with acetate of potassa. The least trace of arsenic will be detected by the strong and offensive odour produced, owing to the formation of cacodyle. In the second, the subnitrate of bismuth is heated with pure muriatic acid. If arsenic be present it will rise in vapours in the form of chloride. These should be carefully collected and condensed, and then treated with an excess of sulphuretted hydrogen. The sulphuret of arsenic precipitated will be the measure of the metal. (*Ann. de Thérap.*, 1868, p. 176.) M. Lassaigne has found as much as 27 per cent. of chloride of bismuth in this preparation, when obtained by precipitating, with water, a solution of bismuth in a mixture of nitric and muriatic acids. The same impurity is introduced, to a small extent, by using common water containing chlorides; and subsulphate of bismuth renders the preparation impure, when the water used contains sulphate of lime. (*Journ. de Chim. Méd.*, Mai, 1855, p. 276.) These facts show the necessity of using distilled water. As regards the origin of the chlorine sometimes existing in commercial subnitrate of bismuth, it is asserted by Mr. R. C. Tichborne to be a common practice with the manufacturer, in order to save the bismuth existing in the mother-liquor, after the deposition of the subnitrate, to precipitate it with chloride of sodium, thus obtaining an insoluble oxychloride of bismuth, which is then added to the previous product. (*Pharm. Journ.*, Feb. 1860, p. 413.) The new metal thallium is said to be present in most specimens of the pharmaceutical preparations of bismuth. For the modes of detecting and separating it, the reader is referred to the *Chemical News* (March 7, 1863, p. 109). Phosphate of lime has been ascertained to be an occasional adulteration of the subnitrate. A ready method of detecting it, suggested by M. Roussin, has proved to be fallacious, and may lead to false decisions as to the presence of the phosphate, and thus injuriously compromise the reputation of individuals. There can be no difficulty in detecting the adulteration by reliable tests. Subnitrate of bismuth was called, by the earlier chemists, *magistery of bismuth.* It consists of one eq. of nitric acid 54, one of teroxide of bismuth 237, and one of water 9 = 300. When heated to redness it loses 20 per cent. of its weight. *U. S.*

Medical Properties. Subnitrate of bismuth is antispasmodic, absorbent, and slightly sedative and astringent. When its use is too long continued it produces scorbutic symptoms, a proof that it is absorbed. It was first used as a medicine by Dr. Odier, of Geneva. It is principally employed in painful affections of the stomach, such as cardialgia, pyrosis, and gastrodynia, in spasmodic diseases, and in dysentery and diarrhœa. Rayer employed it with advantage in the diarrhœa of phthisis and typhus, and Aran recommended it in the obstinate form of the complaint which sometimes follows typhoid fever. It has been used also in dysentery. M. Monneret particularly insists upon the remarkable efficacy of the medicine, given in very large doses, in chronic gastro-intestinal affections, attended with diarrhœa; a plan of treatment which has been followed by several practitioners with advantage. M. Trousseau has successfully employed subnitrate of bismuth in the diarrhœa of children in the form of enema, in the dose of

two scruples, mixed with thick flaxseed tea. M. Monneret uses it thus in much larger doses. He thinks that in diarrhœa its action is entirely local; but this view is combated by Dr. Lussanna, who believes that a part of the medicine enters the circulation, though it never passes into the urine. Its use always blackens the stools. The dose of subnitrate of bismuth, usually prescribed, is five grains, gradually increased to fifteen, twice or thrice a day, given in pill, or mixed with sweetened water. Upon the plan of large doses, recommended by M. Monneret, from half an ounce to an ounce is given daily, in divided doses, in the diarrhœa of adults; from half a drachm to a drachm in that of infants; and from a drachm to two drachms in painful affections of the stomach. In these large doses the medicine is said to be perfectly safe; and yet Orfila mentions, as resulting from an overdose, gastric distress, nausea, vomiting, diarrhœa or constipation, colic, heat in the breast, slight rigors, vertigo, and drowsiness. These effects are to be combated by mucilaginous drinks, enemata, and emollient fomentations, and, in case of inflammation, by bleeding, both general and local. The contradictory statements as to the safety of the preparation can be explained only on the supposition that it is sometimes rendered poisonous by the presence of arsenic, chloride of bismuth, or free nitric acid; and a strong motive is thus furnished to the apothecary to prepare the medicine with the greatest care. M. Rodolfi, of Breccia, has found the use of the subnitrate, associated with bicarbonate of soda and sulphur, to be very efficient in controlling the night sweats of phthisis. Seven or eight grains of the bicarbonate with two or three grains of each of the other ingredients, may be taken every two hours. The favourable effect may be expected in four or five days. (*Journ. de Pharm.*, 4e sér., iii. 468.)

M. Monneret recommends the external use of subnitrate of bismuth as a drying application. In the treatment of ulcers, especially scrofulous ones, provided no risk would be incurred by stopping the discharge, he sprinkles the powder over the whole ulcerated surface. M. E. Caby has used it as a topical application in leucorrhœa, gonorrhœa, and gleet. When used in leucorrhœa, the entire surface of the vagina is dusted with the powder. The injection for gonorrhœa or gleet is made by mixing with water as much of the subnitrate as can be conveniently suspended. Three parts of the salt to twenty of water have been recommended. A portion of the mixture is injected thrice daily, and, each time, retained five minutes. Dr. W. R. Hamilton, of St. Augustine, Illinois, has employed it advantageously for preventing pitting in smallpox. He applies it to the face twice a day, after lubricating the surface with olive oil. (*Am. Journ. of Med. Sci.*, Oct. 1865, p. 563.) The external use of subnitrate of bismuth is attended with no pain. (*Ranking's Abstract*, xx. 188.)

Off. Prep. Trochisci Bismuthi, *Br.* B.

BISMUTHUM PURIFICATUM. *Br. Purified Bismuth.*

"Take of Bismuth *ten ounces*, Nitrate of Potash in powder *two ounces*. Put the Bismuth and one ounce of the Nitrate of Potash into a crucible, and heat them to a temperature at which both the metal and the salt are fused. Continue the heat, constantly stirring the contents of the crucible, for fifteen minutes, or until the salt has solidified into a slag over the metal. Then remove the salt, add the remainder of the nitrate of potash to the bismuth in the crucible, and repeat the process as before. Finally, pour the Bismuth while fused into a suitable mould and allow it to cool." *Br.*

A mode of purifying bismuth is given in the U. S. Pharmacopœia in the process for preparing the subcarbonate and subnitrate. (See *pages* 1062 and 1064.) That of the Br. Pharmacopœia is different; consisting in the oxidizement of the arsenic and other contaminating metals that may be present, by means of the nitric acid of the nitre, and their consequent separation from the bismuth, the great mass of which remains behind unaffected. This method was referred to in the twelfth edition of the Dispensatory (p. 1025); where also the plan of M. W. Pierre is mentioned, consisting in the addition of from 2·5 to 5 per cent. of zinc to the bismuth, and strongly heating the mixture in a

crucible, with a piece of charcoal to prevent the oxidation of the zinc. Both the arsenic and zinc are driven off. (*Chem. News*, Jan. 16, 1861.)

"Dissolved in a mixture of equal volumes of nitric acid and distilled water, it forms a solution which by evaporation yields colourless crystals, that are decomposed on the addition of water, giving a white precipitate. If the mother-liquors from which the crystals have been separated be added to solution of carbonate of ammonia, the precipitate formed and the solution are free or nearly free from colour" (*Br.*); indicating the total or almost total absence of metals that yield coloured salts, as copper, iron, &c.

CADMIUM.

Preparation of Cadmium.

CADMII SULPHAS. *U.S. Sulphate of Cadmium.*

"Take of Cadmium, in small pieces, *a troyounce;* Nitric Acid *two troyounces;* Carbonate of Soda *three troyounces;* Sulphuric Acid *four hundred and twenty grains;* Distilled Water *a sufficient quantity.* To the Cadmium and two fluidounces of Distilled Water, introduced into a glass vessel, add by degrees the Nitric Acid, and, when the action slackens, apply a gentle heat until the metal is dissolved. Filter the solution, and, having dissolved the Carbonate of Soda in six fluidounces of Distilled Water, mix the solutions thoroughly. Wash the precipitate obtained until the water passes tasteless, and dissolve it in the Sulphuric Acid, diluted with four fluidounces of Distilled Water. Then evaporate the solution to one-third, and set it aside to crystallize. Lastly, dry the crystals on bibulous paper." *U. S.*

A nitrate of cadmium is first formed, in consequence of the greater facility with which nitric acid acts upon that metal than sulphuric acid. The cadmium is oxidized at the expense of a part of the acid, with the production of hyponitric acid fumes, and the resulting oxide unites with the undecomposed part of the acid to form the nitrate. This is then decomposed in solution by carbonate of soda, with a mutual interchange of principles; the nitric acid of the nitrate of cadmium taking the soda of the carbonate, and forming nitrate of soda which is retained in solution, while the carbonic acid and oxide of cadmium combine to produce the insoluble carbonate of that metal, which is deposited. This, having been washed, is treated with dilute sulphuric acid, by which the carbonic acid is expelled, and the sulphate of cadmium generated in solution, from which it is obtained by concentration and crystallization.

Properties. Sulphate of cadmium crystallizes in oblique prisms with rhomboidal bases, which are transparent and colourless, and said to resemble those of sulphate of zinc. They have an astringent, slightly acidulous, and austere taste, effloresce on exposure to the air, and are very soluble in water. The solution, even though acidulated, gives with hydrosulphuric acid a yellow precipitate, becoming orange-yellow, of sulphuret of cadmium, which is dissolved by strong muriatic acid, but is insoluble in solutions of potassa or ammonia, and is thus readily distinguished from the sulphuret of arsenic. With hydrosulphate of ammonia it gives a yellow precipitate insoluble in an excess of the hydrosulphate. Ammonia produces a white precipitate, soluble in an excess of the precipitant; carbonate of ammonia a white one insoluble in an excess; ferrocyanide of potassium a white precipitate not dissolved by muriatic acid; and the ferridcyanide a brownish-yellow one soluble in a large excess of that acid. (*Brande & Taylor.*) By these tests sulphate of cadmium is distinguished as a salt of that metal. As a sulphate it is known by yielding a precipitate with chloride of barium not soluble in nitric acid. Zinc precipitates cadmium in the metallic state from the solution. Cadmium suspended in a solution of sulphate of copper precipitates that metal, leaving sulphate of cadmium in solution; and this has been proposed as a method of obtaining the salt. The formula of sulphate of cadmium as com-

monly given is $CdO,SO_3 + 4HO$; but, according to M. de Hauer, it is said to have eight eqs. of water for every three of the salt, and its formula is $3(CdO, SO_3) + 8HO$. (*Chem. News*, Nov. 29, 1862, p. 268.) W.

Medical Uses. Sulphate of cadmium is said to resemble sulphate of zinc as an astringent and emetic. Besides these properties, it possesses, according to M. Grimaud, valuable powers as a remedy in syphilis, rheumatism, and gout. As yet it has been used almost exclusively as an astringent and stimulating remedy in diseases of the eyes. In specks and opacities of the cornea it has been employed successfully by both American and European surgeons. It is used either in solution, in the proportion of from half a grain to four grains to the fluidounce of distilled water, or in the form of ointment, made by mixing two grains with four scruples of fresh lard. M. Fronmüller has employed it, with excellent results, in specks of the cornea, dissolved in rose-water in the proportion of three grains to two fluidounces, conjoined with from half a fluidrachm to a fluidrachm and a half of wine of opium. We have had no experience with sulphate of cadmium as an internal remedy, and can give no authoritative statement as to the proper dose. Nor does this appear to have been well determined; for, while on the one hand we are told that it is ten times as strong as sulphate of zinc, on the other it is said to be used for the same purposes and in the same doses as that salt. (Bouchardat, *Ann. de Thérap.*, 1857, p. 231.) B.

CALX.

Preparations of Lime.

The liquid preparations of lime, *Liquor Calcis* and *Liquor Calcii Chloridi*, have, in conformity with the present edition of the U. S. Pharmacopœia, been transferred to the *Solutions*. (See *Liquores*.)

CALCIS CARBONAS PRÆCIPITATA. *U. S., Br. Precipitated Carbonate of Lime.*

"Take of Solution of Chloride of Calcium *five pints and a half;* Carbonate of Soda *seventy-two troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Carbonate of Soda in six pints of Distilled Water. Heat this solution and the Solution of Chloride of Calcium, separately, to the boiling point, and mix them. After the precipitate has subsided, separate it from the supernatant liquid by decantation, and wash it with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver. Lastly, dry the precipitate on bibulous paper." *U. S.*

"Take of Chloride of Calcium *five ounces* [avoirdupois]; Carbonate of Soda *thirteen ounces* [avoird.]; Boiling Distilled Water *a sufficiency.* Dissolve the Chloride of Calcium and the Carbonate of Soda each in two pints [Imperial measure] of the Water; mix the two Solutions; and allow the precipitate to subside. Collect this on a calico filter, wash it with boiling Distilled Water until the washings cease to give a precipitate with nitrate of silver, and dry the product at the temperature of 212°." *Br.*

These processes do not essentially differ. In each a mutual interchange of principles takes place, resulting in the production of chloride of sodium which remains in solution, and carbonate of lime which is deposited. Any peculiar advantage of the preparation must depend on the minute division of its particles. According to Dr. Bridges, this effect is best obtained by employing the solutions at the boiling temperature, a precaution which is observed in both the present officinal processes. (*Am. Journ. of Pharm.*, xvi. 163.) When properly made, it is a very pure carbonate of lime, in the form of a fine white powder, free from grittiness, insoluble in water, but wholly soluble in dilute muriatic acid with copious effervescence. These properties serve to distinguish it from sulphate of lime, with which it is sometimes adulterated, and which has even been sold for it. It is known to be a salt of lime by giving a copious white precipitate with oxalate of ammonia, when this is added to its solution in muriatic acid, previously neutralized by ammonia. It is dissolved by nitric acid, giv-

ing a clear solution, which if perfectly neutral, and boiled to drive off carbonic acid, gives no precipitate with saccharated solution of lime in excess, or with nitrate of silver, showing the absence of phosphates and chlorides. Its formula is CaO,CO_2, and equivalent number 50. For ordinary use, it probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness. It is preferred by some to chalk in the preparation of tooth-powders. It is frequently sold in the shops under the name of *creta præcipitata*. The dose is from 10 to 40 grains or more.

Off. Prep. Trochisci Bismuthi, *Br.* W.

CALCIS HYDRAS. *Br. Slaked Lime.*

"Take of Lime *two pounds* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Place the Lime in a metal pot, pour the Water upon it, and when vapour ceases to be disengaged cover the pot with its lid, and set it aside to cool. When the temperature has fallen to that of the atmosphere, put the slaked lime on an iron-wire sieve, and by gentle agitation cause the fine powder to pass through the sieve, rejecting what is left. Put the powder into a well-stopped bottle, and keep it excluded as much as possible from the air. Slaked Lime should be recently prepared." *Br.*

The U. S. Pharmacopœia has no separate formula for this preparation, but directs it to be made when at any time it may be wanted. In the process of slaking, water combines with lime to form a solid hydrate, with the evolution of much heat and the escape of white vapours, which consist of steam holding particles of lime in suspension. By union with water the lime acquires a whiter colour, and, if previously in masses, becomes much softer, swelling up, and breaking into a coarse soft powder or friable lumps. When perfectly dry, it consists of one eq. of each of its constituents, with the formula CaO,HO. For the properties of lime the reader is referred to the head of *Calx*, in *Part* I. Hydrate of lime is used exclusively as a pharmaceutical agent.

CALCIS PHOSPHAS PRÆCIPITATA. *U. S.* Calcis Phosphas. *Br. Precipitated Phosphate of Lime. Phosphate of Lime.*

"Take of Bone, calcined to whiteness, and in fine powder, *four troyounces;* Muriatic Acid *eight troyounces;* Water of Ammonia *twelve fluidounces*, or *a sufficient quantity;* Distilled Water *a sufficient quantity*. Macerate the Bone with the Acid, diluted with a pint of Distilled Water, until it is dissolved, and filter the solution. Add another pint of Distilled Water, and then, gradually, Water of Ammonia, until the liquid acquires an alkaline reaction. Mix the precipitate obtained, while yet in the state of magma, with twice its bulk of boiling Distilled Water, and pour the whole upon a strainer. Wash the precipitate with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver, acidulated with nitric acid. Lastly, dry the precipitate with a gentle heat." *U. S.*

"Take of Bone Ash *four ounces* [avoirdupois]; Hydrochloric Acid *six fluidounces* [Imperial measure]; Water *two pints* [Imp. meas.]; Solution of Ammonia *twelve fluidounces*, or *a sufficiency;* Distilled Water *a sufficiency*. Digest the Bone Ash in the Hydrochloric Acid diluted with a pint of Water, until it is dissolved. Filter the solution, if necessary; add the remainder of the Water, and afterwards the Solution of Ammonia, until the mixture acquires an alkaline reaction; and, having collected the precipitate on a calico filter, wash it with boiling Distilled Water as long as the liquid which passes through occasions a precipitate, when dropped into solution of nitrate of silver acidulated with nitric acid. Dry the washed product at a temperature not exceeding 212°." *Br.*

This preparation, whatever opinion may be entertained of its real powers, has been very properly introduced into the U. S. Pharmacopœia, as it is considerably used, and is by some much esteemed.

The muriatic acid dissolves the phosphate of lime of the bones, and lets it fall, on the addition of ammonia, in a state of minute division. The ablution is intended to free it from adhering muriate of ammonia. The salt thus obtained is, for the sake of distinction, called *bone phosphate of lime.* It is a white powder, without taste or smell, insoluble in water, but very soluble in nitric, muriatic, and acetic acids, from which it is precipitated unchanged by ammonia. By an intense heat it is fused, but is not otherwise changed. It consists, according to Mitscherlich, of one equivalent of phosphoric acid and three of lime.

The chemical characteristics of bone phosphate of lime, besides those mentioned, are that with its solution in dilute nitric acid, oxalate of ammonia produces a white precipitate of oxalate of lime, and acetate of lead a white precipitate of phosphate of lead; and, if the nitric solution be neutralized as far as possible without causing a permanent precipitate of phosphate of lime, ammoniacal nitrate of silver throws down from it a lemon-yellow precipitate of phosphate of silver. (*Christison's Dispensatory.*) "Ten grains dissolve perfectly and without effervescence in diluted hydrochloric acid, and the solution yields with ammonia a white precipitate, insoluble in boiling solution of potash, and weighing ten grains when washed and dried." *Br.*

Medical Uses. In the form of burnt hartshorn, phosphate of lime formerly enjoyed a brief popularity in the treatment of rickets and mollities ossium, in which its use seemed to be indicated upon obvious chemical grounds. It has recently been again brought into notice in consequence of the suggestion by Benecke (*London Lancet*, July, 1851), that, as it is essential in animals as well as plants to the formation of cells, it might be found useful in certain pathological states of the system characterized by defective nutrition, such as the scrofulous affections. Upon considerations of this kind, the late Dr. W. Stone, of New Orleans, was induced to employ it in cases of scrofulous ulceration, phthisis, &c., and with considerable supposed advantage. (See *St. Louis Med. and Surg. Journ.*, x. 38.) Subsequently, it has been used by other practitioners, and, in connection with other phosphates, as those of iron, soda, and potassa, has acquired no little reputation in different forms of scrofula and phthisis. When, however, it is considered that, in ordinary food, there is more of the phosphates than the system has need of, so that they are constantly escaping with the stools; and that in those very disorders in which they are supposed to be indicated they are not unfrequently in excess in the blood and urine, in consequence, probably, of the rapid disintegration of the tissues, it would seem doubtful whether the want, in scrofulous cases, is so much that of materials for cells as of due power to appropriate those materials. In the reported cases, the phosphate of lime has generally been administered in connection with cod-liver oil or other tonics; to which, there is reason to believe, any benefit experienced is more truly ascribable than to the phosphate. In two of Dr. Stone's cases the good effects began to be experienced at the period when they might have been expected from the oil alone. Phosphate of lime is thought to have proved useful by hastening the union of fractured bones; and M. Alphonse Milne-Edwards is said to have shown, by experiments upon dogs and rabbits, that, in these animals, the callus in fractured bones forms more quickly under its use than without it. (*Med. Times and Gaz.*, May, 1856, p. 489.) M. Piorry also has derived material advantage from the phosphate of lime in two cases of softened bone supposed to have depended on a venereal taint. (See *Am. Journ. of Med. Sci.*, April, 1865, p. 512.) Its use in curvature of the spine and rickety affections in general has also been revived by M. Piorry and others. Though insoluble in water, it is probably in general dissolved by the gastric liquids, in consequence of the acid present in them; and, if desirable, it may readily be administered in solution by the addition of one of the acids mentioned in the above account of its chemical properties. The dose is from ten to thirty grains.*

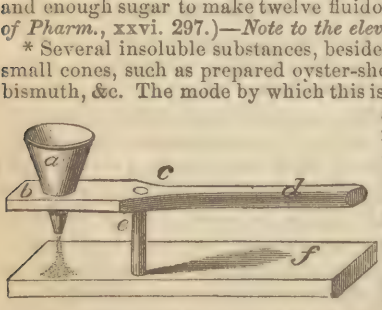
* *Syrup of Phosphate of Lime.* Mr. T. S. Wiegand has proposed a syrup of phosphate of lime, to be made in the following manner. Take of the precipitated phosphate ℥j, mu-

CRETA PRÆPARATA. *U. S.*, *Br. Prepared Chalk.*

"Take of Chalk *a convenient quantity*. Add a little water to the Chalk, and rub it into fine powder. Throw this into a large vessel nearly full of water, stir briskly, and, after a short interval, decant the supernatant liquor, while yet turbid, into another vessel. Treat the coarser particles of the Chalk, remaining in the first vessel, in a similar manner, and add the turbid liquid to that previously decanted. Lastly, set the liquid by that the powder may subside, and, having poured off the water, dry the powder." *U. S.*

The Br. Pharmacopœia has abandoned its former process, and is now content with defining the medicine to be "chalk freed from most of its impurities by elutriation, and afterwards dried in small masses, which are usually of a conical form."



The object of the above process is to reduce chalk to a very fine powder. The mineral, previously pulverized, should be rubbed with a little water upon a porphyry slab, by means of a muller of the same material. Having been thus very minutely divided, it is agitated with water, which upon standing a short time deposits the coarser particles, and, being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation*, the latter *elutriation*. The soft mass which remains after the decanting of the clear liquor is made to fall upon an absorbent surface in small portions, which when dried have a conical shape.* Practically, prepared chalk is generally made on the large scale from *whiting* by the manufacturer. For the particulars of the process the reader is referred to the *Pharm. Journ.* (vii. 416).

Medical Properties and Uses. This is the only form in which chalk is used in medicine. It is an excellent antacid; and, as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to diarrhœa accompanied with acidity. It is also sometimes used in acidity of stomach attending dyspepsia and gout, when a laxative effect is to be avoided; is one of the best antidotes for oxalic acid; and has been recommended in rachitis. In scrofulous affections it may sometimes do good by forming soluble salts with acid in the primæ viæ, and thus finding an entrance into the blood-vessels. It is frequently employed as an application to burns and ulcers, which it moderately stimulates, while it absorbs the ichorous discharge, and thus prevents it from irritating the diseased surface, or the sound skin. It is given internally in the form of powder, or suspended in water by the intervention of gum arabic and sugar. (See *Mistura Cretæ*.) It is better fitted for the chalk mixture than the precipitated carbonate of lime, in consequence of its more impalpable character. The dose is from ten to forty grains or more.

Pharm. Uses. In preparing Acidum Citricum, *Br.*; Acidum Tartaricum, *Br.*; Zinci Chloridum, *U. S.*

riatic acid f℥ss, water f℥vij, sugar q. s. Mix the phosphate with a fluidounce of the water; add the acid; filter the resulting solution; then add the remainder of the water, and enough sugar to make twelve fluidounces of syrup; and, finally, strain. (*Am. Journ. of Pharm.*, xxvi. 297.)—*Note to the eleventh edition.*

* Several insoluble substances, besides chalk, are brought habitually into the form of small cones, such as prepared oyster-shell, phosphate of lime, rust of iron, subnitrate of bismuth, &c. The mode by which this is effected is by the use of a simple implement, consisting of a funnel of tinned-iron, with the neck removed (*a*), fixed at the expanded extremity (*b*) of a piece of wood about a foot long (*c*), having its other end in the form of a handle (*d*), with a stout piece of wood about 4 inches long (*e*), attached perpendicularly to the lower side of it, so as to serve as a support when fixed in a socket. The material to be shaped is introduced in a very soft, almost diffluent state into the funnel, and the instrument, then raised in the hand by the handle, is brought down so that its support shall strike with a gentle shock against a flat surface of chalk stone (*f*), and these little shocks are rapidly repeated. At each one of them a small portion of the soft mass escapes from the mouth of the funnel, and falls on the stone, where it hardens into the shape of a cone; the chalk serving to absorb the moisture rapidly, and thus enabling it quickly to solidify. (*Note to the twelfth edition.*)

Off. Prep. Hydrargyrum cum Cretâ; Mistura Cretæ; Pulvis Cretæ Aromaticus, *Br.;* Trochisci Cretæ, *U. S.* W.

TESTA PRÆPARATA. *U. S. Prepared Oyster-shell.*

"Take of Oyster-shell *a convenient quantity.* Free the Oyster-shell from extraneous matter, wash it with boiling water, and, having reduced it to a fine powder, treat this in the manner directed for Prepared Chalk." *U. S.*

Prepared oyster-shell differs from prepared chalk in containing animal matter, which, being very intimately blended with the carbonate of lime, is supposed by some physicians to render the preparation more acceptable to a delicate stomach. It is given as an antacid in diarrhœa, in the dose of from ten to forty grains or more, frequently repeated. A preparation has been introduced, within a few years, into use in this country, under the name of *Castillon's powders*, consisting of sago, salep, and tragacanth, each, in powder, *a drachm*, prepared oyster-shell *a scruple*, and sufficient cochineal to give colour to the mixture. A drachm of this is boiled in a pint of milk, and the decoction used *ad libitum* as a diet in chronic bowel affections. W.

CARBO.

Preparation of Charcoal.

CARBO ANIMALIS PURIFICATUS. *U. S.*, *Br. Purified Animal Charcoal.*

"Take of Animal Charcoal, in fine powder, Muriatic Acid, each, *twelve troy-ounces;* Water *twelve fluidounces.* Pour the Muriatic Acid, previously mixed with the Water, gradually upon the Charcoal, and digest with a gentle heat for two days, occasionally stirring the mixture. Having allowed the undissolved portion to subside, pour off the supernatant liquid, wash the Charcoal frequently with water until the washings cease to afford a precipitate with the nitrate of silver, and dry it." *U. S.*

"Take of Bone Black, in powder, *sixteen ounces* [avoirdupois]; Hydrochloric Acid, *ten fluidounces;* Distilled Water *a sufficiency.* Mix the Hydrochloric Acid with a pint of the Water, and add the Bone Black, stirring occasionally. Digest at a moderate heat for two days, agitating from time to time; collect the undissolved charcoal on a calico filter, and wash with Distilled Water till what passes through gives scarcely any precipitate with nitrate of silver. Dry the charcoal, and then heat it to redness in a covered crucible." *Br.*

Animal charcoal, as it is made by charring bones, necessarily contains bone-phosphate and carbonate of lime, the presence of which does no harm in some decolorizing operations; but, in delicate chemical processes, these salts may be dissolved or decomposed, and thus become a source of impurity. It is on this account that animal charcoal requires to be purified from its calcareous salts; and this is accomplished by dilute muriatic acid, which dissolves the phosphate and decomposes the carbonate. According to Dr. Stenhouse, aluminized vegetable charcoal may be substituted for purified animal charcoal, and is equally efficacious as a decolorizer. (See *page* 224.)

Purified animal charcoal is a dark brownish-black powder. If it contain carbonate of lime, muriatic acid will cause effervescence, and the solution obtained will give a precipitate with carbonate of ammonia; and if phosphate or sulphate of lime be present, the acid will dissolve the salt, and yield it as a precipitate on the addition of ammonia. In the Br. Pharmacopœia, it is stated that, when burned at a high temperature, with a little red oxide of mercury and free access of air, it leaves only a slight residue.

It has been shown by Mr. Robert Warington that bitter vegetable substances, including the organic alkalies, are removed from solution by passing through *purified* animal charcoal, especially when the action is assisted by heat. M. Weppen finds that a similar effect is produced by it in removing resins from tinctures, tannic acid and bitter principles from astringent and bitter infusions,

and certain metallic salts from their solutions. Purified animal charcoal, thus employed, has been resorted to by M. Lebourdais as an agent for obtaining the active principles of plants. A decoction or infusion of the plant is either boiled with or filtered through the charcoal, which takes up, more or less completely, the bitter and colouring principles. The charcoal, after having been washed and dried, is treated with boiling alcohol, which dissolves the principles taken up. Finally, the alcohol is distilled off, and the principles are obtained in a separate state. In this way digitaline, ilicin, scillitin, colombin, colocynthin, arnicina, strychnia, quinia, and other principles have been obtained by M. Lebourdais. (*Chem. Gaz.*, Nov. 15, 1848.) In relation to the method of M. Lebourdais, see a paper by Mr. J. S. Cobb, in the *Am. Journ. of Pharm.* for July, 1851, from the London *Pharmaceutical Journal.* Dr. A. B. Garrod has proposed purified animal charcoal as an antidote to vegetable and animal poisons, with which it appears to combine. According to his experiments, common bone-black has not one-fifth of the power possessed by the purified substance; and vegetable charcoal and lampblack are nearly or quite useless. The amount of the antidote proposed by Dr. Garrod is half an ounce for each grain of a vegetable organic alkali. Dr. Alfred Taylor deems the results of Dr. Garrod inconclusive. Prof. B. H. Rand, of this city, has made some interesting observations in relation to the antidotal powers of purified animal charcoal, and has proved that poisonous doses of the strongest vegetable poisons may be swallowed with impunity, if mixed with that substance. (*Med. Exam.*, Sept. 1848.)*

In using animal charcoal for decolorizing active vegetable principles, great caution should be observed, as much loss is often incurred by the absorption of those principles by the charcoal.

* *Revivification of Animal Charcoal.* To the large manufacturing chemist, and in a less degree to the pharmaceutist, it is an object of some importance to revivify the animal charcoal which has lost its absorbent property, and thus to fit it for future use. This has been done by exposing it to an intense heat, so as to decompose all the organic, and drive off all the volatile principles it may have absorbed; but this will not deprive it of fixed inorganic substances which may contaminate it. Messrs. Leplay and Cusinier, in a paper on the use of animal charcoal in the refining of sugar, offer certain principles and suggest certain practical processes in reference to this agent, which are of general interest, and which have appeared to us to merit a notice here. The absorbing powers of animal charcoal are different for different substances, and do not become exhausted simultaneously. For its revivification after use, different measures are required in accordance with the degree to which its powers may have been lost. There are, indeed, means of increasing these absorbent powers even beyond the degree to which they may have been originally possessed. None of these revivifying measures require a heat above 212°. The following are the practical principles. 1. When animal charcoal is employed in filtering, its first series of absorbing powers are exhausted at furthest in four hours. These are such as affect "viscid, nitrogenous, ammoniacal, sapid, and odorous matters." In regard to these the original power is entirely restored by passing a current of steam through the granulated animal charcoal contained in the filter; and it can be restored indefinitely. 2. The second series of absorbing powers concern free alkalies, as potash, soda, lime, and their salts; and require a much longer time for their exhaustion, to the extent of six or eight times the period required for the first series. These powers are revived by pouring muriatic acid largely diluted with water upon the charcoal in the filter, and afterwards by prolonged washing with water. 3. The third series of absorbing powers embrace colouring principles, and continue thirty or forty times longer than the first. For the restoration of these powers the measure deemed most efficient is washing with weak boiling solutions of the caustic alkalies. All these measures may be applied to the charcoal still contained in the filter, or removed to a special apparatus for the purpose. 4. These methods restore the original properties. To give additional absorbent powers, a solution of biphosphate of lime is poured upon the animal charcoal still containing its original tribasic phosphate. When these salts meet, a new phosphate is produced with two eqs. of base, which is insoluble in water, has no acid reaction, and possesses very energetic powers of absorption. (See *Am. Journ. of Pharm.*, Nov. 1862, p. 552.)—*Note to the twelfth edition.*

For some valuable statements by Dr. Wallace in reference to the animal charcoal used in sugar-refining in Scotland, for which we have not space here, see a paper in the *American Journal of Pharmacy* (Sept. 1868, p. 425); from the *Transactions of the Philosophical Society of Glasgow.* (*Note to the thirteenth edition.*)

CATAPLASMATA.

Cataplasms.

Cataplasms or *poultices* are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over the neighbouring parts, or so tenacious as to adhere firmly to the skin. As they are in this country seldom made by the apothecary, they were not deemed by the compilers of the U. S. Pharmacopœia proper objects for officinal direction. The ounce used in the following processes is the avoirdupois. W.

CATAPLASMA CARBONIS. *Br.* *Charcoal Poultice.*

"Take of Wood Charcoal, in powder, *half an ounce;* Crumb of Bread *two ounces;* Linseed Meal *one ounce and a half;* Boiling Water *ten fluidounces.* Macerate the Bread in the Water for ten minutes near the fire, then mix, and add the Linseed Meal gradually, stirring the ingredients, so that a soft poultice may be formed. Mix with this half the Charcoal, and sprinkle the remainder on the surface of the poultice." *Br.*

Charcoal, recently prepared, has the property of absorbing those principles upon which the offensive odour of putrefying animal substances depends. In the form of poultice, it is an excellent application to foul and gangrenous ulcers, correcting their fetor, and improving the condition of the sore. It should be frequently renewed. W.

CATAPLASMA CONII. *Br.* *Hemlock Poultice.*

"Take of Hemlock Leaf, in powder, *one ounce;* Linseed Meal *three ounces;* Boiling Water *ten fluidounces.* Mix the Hemlock and Linseed Meal, and add them to the Water gradually, constantly stirring." *Br.*

This cataplasm may be advantageously employed as an anodyne application to cancerous, scrofulous, syphilitic, and other painful ulcers; but its liability to produce narcotic effects, in consequence of the absorption of the active principle of the hemlock, should not be overlooked. W.

CATAPLASMA FERMENTI. *Br.* *Yeast Poultice.*

"Take of Beer Yeast *six fluidounces;* Wheaten Flour *fourteen ounces;* Water, heated to 100°, *six fluidounces.* Mix the Yeast with the Water, and stir in the Flour. Place the mass near the fire till it rises." *Br.*

By exposing a mixture of yeast and flour to a gentle heat, fermentation takes place, and carbonic acid gas is extricated, which causes the mixture to swell, and is the source of its peculiar virtues. The yeast cataplasm is gently stimulant, and is sometimes applied with benefit to foul and gangrenous ulcers, the fetor of which it corrects, while it is supposed to hasten the separation of the slough. The carbonic acid may also act as an anæsthetic agent. W.

CATAPLASMA LINI. *Br.* *Linseed Poultice.*

"Take of Linseed Meal *four ounces;* Olive Oil *half a fluidounce;* Boiling Water *ten fluidounces.* Mix the Linseed Meal gradually with the Water, then add the Oil with constant stirring." *Br.*

The flaxseed meal which remains after the expression of the oil is here employed; but that which has not been submitted to pressure is decidedly preferable, and answers an excellent purpose when mixed with boiling water, without other addition. Fresh lard or olive oil, spread upon the surface of the poultice, serves to prevent its adhesion to the skin, and to preserve its softness.

The use of this and other emollient cataplasms is to relieve inflammation, or to promote suppuration. They act mainly by the sedative influence of their moisture, and by excluding the air. The one most extensively employed, perhaps because its materials are always at hand, is that prepared by heating together milk and the crumb of bread. The milk should be quite sweet, and fresh lard

should be incorporated with the poultice. Mush made with the meal of Indian corn also forms an excellent emollient cataplasm. W.

CATAPLASMA SINAPIS. *Br. Mustard Poultice.*

"Take of Mustard, in powder, Linseed Meal, each, *two ounces and a half;* Boiling Water *ten fluidounces.* Mix the Linseed Meal gradually with the Water, and add the Mustard, with constant stirring." *Br.*

The simplest and most effectual mode of preparing a mustard poultice, is to mix the powdered mustard of the shops with a sufficient quantity of warm water to give it a due consistence. When a weaker preparation is required, an equal portion or more of rye or wheat flour should be added. Vinegar never increases its efficiency, and, in the case of the black mustard seed, has been ascertained by MM. Trousseau and Blanc to diminish its rubefacient power. The same may be said of alcohol. A boiling temperature is also injurious by interfering with the development of the volatile oil or acrid principle. (See *Sinapis.*)

These poultices are frequently called *sinapisms.* They are powerfully rubefacient, exciting a sense of warmth in a few minutes, and usually becoming insupportably painful in less than an hour. When removed they leave the surface intensely red and burning; and the inflammation frequently terminates in desquamation, or even blistering if the application be too long continued. Obstinate ulcers and gangrene also sometimes result from the protracted action of mustard, especially on parts possessed of little vitality. As a general rule, the poultice should be removed when the patient complains much of pain; and in cases of insensibility should not, unless greatly diluted, be allowed to remain longer than one, or at most two hours; as violent inflammation, followed by obstinate ulceration, is apt to take place upon the occurrence of reaction. In children particular care is necessary to avoid this result. The poultice should be thickly spread on linen, and may be covered with gauze or unsized paper in order to prevent its adhesion to the skin. If hairs are present they should be removed by the razor. Sinapisms may be employed in all cases in which it is desirable to produce a speedy and powerful rubefacient impression. W.

CATAPLASMA SODÆ CHLORATÆ. *Br. Chlorine Poultice.*

"Take of Solution of Chlorinated Soda *two fluidounces;* Linseed Meal *four ounces;* Boiling Water *eight fluidounces.* Mix the Linseed Meal gradually with the Water, and add the Solution of Chlorinated Soda, with constant stirring." *Br.*

This is an excellent application to sloughing and other fetid ulcers, to correct the smell, and afford a moderate stimulation. W.

CERATA.

Cerates.

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or resin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should usually be taken to select the oil or lard perfectly free from rancidity. In reference to the wax, too, there would seem to be a choice, as experience has shown that cerates made with yellow wax keep longer unchanged than those made with white or bleached wax, probably because there is in yellow wax some principle which corrects the tendency of fatty matters to become rancid. (F. Bringhurst, *Am. Journ. of Pharm.*, Jan. 1869, p. 59.) The liquefaction should be effected by a very gentle heat, which may be applied by means of a water-bath; and during the refrigeration the mixture should be well stirred, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the

whole assumes the proper consistence. When a large quantity is prepared, the mortar or other vessel into which the mixture may be poured for cooling, should be previously heated by means of boiling water. It has been proposed to substitute paraffin for wax in the preparation of the cerates; but there has yet been too little trial of it to justify a decision upon its merits. It is, we think, unfortunate that this class of preparations has been abandoned in the British Pharmacopœia; the several cerates having been rejected, or transferred to the class of Ointments. Independently of the connection between the name and one of the characteristic constituents of the cerates, there is a ground of difference between them and the ointments in their consistence; that of the cerates being such as to render them especially suitable for spreading on linen, while that of ointments is peculiarly adapted to inunction. W.

CERATUM ADIPIS. *U.S.* CERATUM SIMPLEX. *U.S.* 1850. *Cerate of Lard. Simple Cerate.*

"Take of Lard *eight troyounces;* White Wax *four troyounces.* Melt them together, and stir the mixture constantly until cool." *U. S.*

We regret the loss of the old name of simple cerate, which always seemed to us very appropriate. Wax was the essential ingredient, while the place of lard might be supplied by olive or almond oil, or any bland fatty matter of a very soft or liquid consistence. Lard, however, is, we think, preferable to olive oil, as it may always be had perfectly sweet, and is the mildest application which can be made to irritated surfaces. In the preparation of this cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition; for the value of the preparation depends on its perfect blandness. To avoid change, it should be put up in small jars, and covered closely with tin foil so as to exclude the air. It is used for dressing blisters, wounds, &c., in all cases in which the object is to prevent the contact of air and preserve the moisture of the part, and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose lard should be used in winter, and simple ointment in summer; the cerate having too firm a consistence. W.

CERATUM CANTHARIDIS. *U.S.* EMPLASTRUM CANTHARIDIS. *Br. Cerate of Cantharides. Blistering Cerate. Cerate of Spanish Flies. Cantharides Plaster.*

"Take of Cantharides, in very fine powder, *twelve troyounces;* Yellow Wax, Resin, each, *seven troyounces;* Lard *ten troyounces.* To the Wax, Resin, and Lard, previously melted together and strained through muslin, add the Cantharides, and, by means of a water-bath, keep the mixture in a liquid state for half an hour, stirring occasionally; then remove it from the water-bath, and stir it constantly until cool." *U. S.*

The *British Pharmacopœia* directs of Cantharides, in powder, *twelve ounces* (avoirdupois); Yellow Wax, and Prepared Suet, each, *seven ounces and a half;* Prepared Lard *six ounces;* and Resin *three ounces;* melts the Wax, Suet, and Lard together, by a water-bath, and adds the Resin previously melted; then introduces the Cantharides, mixes the whole thoroughly, and continues to stir the mixture while cooling.

This is the common *blistering plaster* of the shops. As it can be readily spread without the aid of heat, it is properly a cerate, and is, therefore, correctly named in the U. S. Pharmacopœia. It is essentially the same as prepared by the two processes; though the U. S. formula has a decided advantage over the British, in keeping the mixture of the flies and the other ingredients for some time at an elevated temperature, while, in the latter, they are allowed to cool after being mixed with the fatty matters. Care was formerly considered requisite, in making the cerate, not to injure the flies by heat. It was, therefore, recommended that they should not be added to the other ingredients until immediately before these begin to stiffen, after having been removed from the fire;

and, though this direction has been omitted, no provision is made for the continued application of heat. From the experiments of Mr. Donovan (*Dublin Med. Press*, Aug. 1840), and those of Professor Procter (*Am. Journ. of Pharm.*, xiii. 302, and xxiv. 296), it may be inferred that the vesicating principle of Spanish flies is not injured or dissipated by a heat under 300° F., and that an elevated temperature, instead of being hurtful, is positively advantageous in the preparation of the cerate. The cantharidin is thus more thoroughly dissolved by the oleaginous matter, and consequently brought more efficiently into contact with the skin, than when retained in the interior of the tissue of the fly. Another advantage, stated by Donovan, is that the moisture, usually existing to a certain extent in all the ingredients of the cerate, is thus dissipated, and the preparation is less apt to become mouldy, or otherwise to undergo decomposition. Instead, therefore, of waiting until the melted wax, resin, and lard begin to stiffen, it is better to add the powder before the vessel is removed from the fire. Mr. Donovan recommends that, as soon as the other ingredients are melted, the powdered flies should be added, and the mixture stirred until the heat is shown by a thermometer to have risen to 250°, when the vessel is to be removed from the fire, and the mixture stirred constantly until cool. At the heat mentioned, ebullition takes place in consequence of the escape of the moisture contained in the materials. In the cerate thus prepared, the active matter has been dissolved by the lard, and the powder may be separated, if deemed advisable, by straining the mixture before it solidifies. Care should be taken that the temperature be not so high as to decompose the ingredients; and it would be better to keep it within 212° by means of a water-bath, as in the U. S. process, than to incur any risk from its excess. Violent irritation and even vesication of the face of the operator are stated to have resulted from exposure to the vapours of the liquid, at a temperature of 250°. (*Pharm. Journ.*, ii. 391.) From an experiment, however, of Prof. Procter, it appears that, though cantharidin begins to volatilize slightly at 250°, and rapidly rises in vapour and sublimes at from 402° to 412°, yet it is not decomposed unless by increasing the heat considerably above the last-mentioned point. (*Am. Journ. of Pharm.*, xxiv. 296 and 298.) It is desirable that the flies should be very finely pulverized. Powdered euphorbium is said to be sometimes fraudulently added.

The cerate will always raise a blister in ordinary conditions of the system, if the flies are good, and not injured in the preparation. It should be spread on soft leather, though linen or even paper will answer the purpose when that is not to be had. An elegant mode of preparing it for use is to spread a piece of leather, of a proper size, first with adhesive plaster, and afterwards with the cerate, leaving a margin of the former uncovered, in order that it may adhere to the skin. Heat is not requisite, and should not be employed in spreading the cerate. Some sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but, if the flies originally employed were good, this addition is superfluous. Prof. Procter is in the habit of applying over the surface with a brush an ethereal tincture of cantharides, which leaves a thin coating of extract, and renders the preparation more certain.

Upon the application of the plaster, the skin should be moistened with warm vinegar or other liquid; and a good rule is to cover the surface of the plaster closely with very thin gauze or unsized paper, which prevents any of the cerate from adhering to the cuticle, and is thought by some to diminish its liability to occasion strangury. In adults, when the full action of the flies is desired, and the object is to produce a permanent effect, the application should be continued for twelve hours, and on the scalp for twenty-four hours. In very delicate persons, however, or those subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as quickly as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a bread and milk

poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum.* In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied. From two to four hours are usually sufficient for any desirable purpose. When the head, or other very hairy part, is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster; so that the abrasions may heal, and some impediment be offered to the absorption of the flies. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but, if it be desirable to maintain the discharge for a short time, resin cerate should be used, and the cuticle removed if it can be done without inconvenience. When it is wished that the blistered surface should heal as soon as possible, and with the least inconvenience to the patient, Dr. Maclagan recommends a dressing of cotton wadding; an emollient poultice being first applied for two hours after the removal of the blistering cerate, the cuticle then cut, and the surface afterwards covered with the cotton, with its raw surface next the skin. Should the dressing become soaked, so much of the cotton may be removed as can be done without disturbing the cuticle, and a new batch applied. The cotton is to be allowed to remain until the old cuticle spontaneously separates. The effects of an issue may be obtained by employing savine ointment, or the ointment of Spanish flies, as a dressing. If much inflammation take place in the blistered surface, it may be relieved by emollient poultices, or weak lead-water. Where there is an obstinate indisposition to heal, we have found nothing so effectual as the cerate of subacetate of lead, mixed with an equal weight of simple cerate. When deep and extensive ulceration occurs in consequence of general debility, bark or sulphate of quinia should be used, with nutritious aliment.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting the *blistering cloth*, *blistering paper*, *vesicating taffetas*, *&c.*, of the shops. The advantages of these preparations are that they occupy less space, are more portable, and, being very pliable, are more easily adapted to irregularities of the surface. Absolutely pure cantharidin is expensive and not requisite; as extracts of cantharides, made with ether, alcohol, or boiling water, will answer every purpose. Henry and Guibourt give the following formula. Digest powdered cantharides in ether, distil off the ether, evaporate the residue by means of a salt-water bath, until ebullition ceases, melt the mass which remains with twice its weight of wax, and spread the mixture upon waxed cloth. The *waxed cloth* may be prepared by spreading upon linen or muslin a mixture composed of 8 parts of white wax, 4 of olive oil, and 1 of turpentine, melted together. An extract of cantharides of a buttery consistence, said to act very efficiently when applied by means of paper greased with it, is prepared by digesting 4 parts of flies with 1 part of strong acetic acid, and 16 of alcohol, straining, filtering, and evaporating at a

*The late Dr. M. B. Smith, of Philadelphia, informed us that he had frequently employed uva ursi, as a preventive of strangury from blisters, and had never found it to fail. He gave a small wineglassful of the officinal decoction (see *Decoctum Uvæ Ursi*) every hour, commencing two hours after the application of the blister. Camphor is sometimes incorporated with the blistering cerate to prevent strangury, though with doubtful effect. A plan proposed by M. Vée is to spread over the surface of the plaster, when ready for delivery, by means of the finger, a saturated solution of camphor in ether. The ether evaporates, leaving a thin coating of camphor uniformly diffused. (*Journ. de Pharm.*, 3e sér., viii. 68.) The late Dr. Joseph Hartshorne, of Philadelphia, was in the habit, in cases where he apprehended strangury, of directing four grains of opium and twenty of camphor to be mixed with the cerate of a blister of large size, and experienced the happiest effects from the addition.

moderate heat. A preparation which received the favourable report of a committee of the Society of Pharmacy, at Paris, is the following, proposed by M. Dubuison. Four parts of a hydro-alcoholic extract of the flies, made by maceration, are mixed with an aqueous solution of one part of pure gelatin, so as to obtain a solution of suitable consistence, which is then applied upon a piece of extended waxed cloth, care being taken that the brush should always have the same direction. When the first layer has dried, a second and a third are to be applied in the same manner. The gelatin renders the cloth more adhesive and less deliquescent. The hydro-alcoholic extract is preferred to the alcoholic, because it contains less of the green oil, which does not readily mix with the other ingredients. The committee, however, preferred the aqueous extract, as cheaper and more active. This taffeta has been tried, and found to raise blisters in four hours. (*Journ. de Pharm.*, 3e sér., viii. 67.) A strong decoction of the flies in olive oil, applied by means of paper, would probably answer a similar purpose with these more elaborate preparations; but none of them is likely to supersede the officinal cerate. For very speedy vesication, an infusion of the flies in strong acetic acid is sometimes employed. A preparation, called *cantharidal collodion*, has within a few years been introduced into use, and has acquired so great a popularity with the profession that it was deemed proper, at the recent revision of the Pharmacopœia, to introduce a formula for its preparation. (See *Collodium cum Cantharide.*)

It is said that the flies, by ebullition with water, are deprived of their property of producing strangury, while their vesicating powers remain unaltered. (*Paris's Pharmacologia.*) Dr. Theophilus Beesley, of Philadelphia, was in the habit of employing a cerate made with cantharides prepared in this manner, and never knew it to produce strangury in more than two or three instances. (*Journ. of the Phil. Col. of Pharm.*, iv. 185.) In a letter addressed to one of the authors by Dr. James Couper, of New Castle, Delaware, a similar method of preparing the flies is recommended as an expedient against strangury, both from his own experience, and that of the late Dr. Groom, of Elkton, Maryland, from whom he derived his knowledge of the plan. Yet there can be no doubt that boiling water extracts cantharidin from the flies; and the cerate made as here recommended must be weaker in the blistering principle than the officinal.

Off. Prep. Emplastrum Picis cum Cantharide, *U. S.* W.

CERATUM CETACEI. *U. S.* *Spermaceti Cerate.*

"Take of Spermaceti *a troyounce;* White Wax *three troyounces;* Olive Oil *five troyounces.* Melt together the Spermaceti and Wax; then add the Oil previously heated, and stir the mixture constantly until cool." *U. S.*

The direction to heat the oil before adding it to the other ingredients is important. If added cold, it is apt to produce an irregular congelation of the wax and spermaceti, and thus to render the preparation lumpy. The cerate is employed as a dressing for blisters, excoriated surfaces, and wounds, and as the basis of more active preparations. When the ingredients are pure and sweet, it is perfectly free from irritating properties. From experiments made by Mr. J. B. Barnes, of London, it appears that this cerate keeps much better when made of unbleached materials, than when prepared with olive oil and wax previously bleached. (*Pharm. Journ.*, Jan. 1861, p. 352.) W.

CERATUM EXTRACTI CANTHARIDIS. *U. S.* *Cerate of Extract of Cantharides.*

"Take of Cantharides, in fine powder, *five troyounces;* Stronger Alcohol *two pints and a half*, or *a sufficient quantity;* Resin *three troyounces;* Yellow Wax *six troyounces;* Lard *seven troyounces.* Moisten the Cantharides with Stronger Alcohol, pack them in a cylindrical percolator, and gradually pour on Stronger Alcohol until the liquid passes nearly colourless. Evaporate the filtered liquid, by means of a water-bath, to the consistence of a soft extract Mix this with the Resin, Wax, and Lard, previously melted together, and keep the whole at the temperature of 212° for fifteen minutes. Lastly, strain the mixture through muslin, and stir it constantly until cool." *U. S.*

This is a new officinal of our Pharmacopœia, adopted from a formula of Mr. Wm. R. Warner, published in the *American Journal of Pharmacy* (Jan. 1860, p. 11), and intended as a substitute for the old *Ceratum Cantharidis*, from which it differs mainly in containing an alcoholic extract of the flies instead of the flies themselves. If the percolation be well conducted, so as to exhaust the cantharides, of which the active matter is soluble in alcohol, this cerate ought theoretically to be more effective than the old blistering cerate; as the active principles are separated from the inert matter of the flies which envelops them in the natural state, and must in some measure interfere with their action; and it is said that its superior efficacy has been practically ascertained. It is to be used in the same manner as the cerate of cantharides. W.

CERATUM PLUMBI SUBACETATIS. *U. S.* Unguentum Plumbi Subacetatis Compositum. *Br.* *Cerate of Subacetate of Lead. Compound Ointment of Subacetate of Lead. Goulard's Cerate.*

"Take of Solution of Subacetate of Lead *two fluidounces and a half;* White Wax *four troyounces;* Olive Oil *eight troyounces;* Camphor *thirty grains.* Mix the Wax, previously melted, with *seven troyounces* of the Oil. Then remove the mixture from the fire, and, when it begins to thicken, gradually pour in the Solution of Subacetate of Lead, stirring constantly with a wooden spatula till it becomes cool. Lastly, add the Camphor, dissolved in the remainder of the Oil, and mix them." *U. S.*

The *British Pharmacopœia* takes *six fluidounces* of the Solution of Subacetate of Lead, *eight ounces* [avoirdupois] of White Wax, *a pint* [Imperial measure] of Oil of Almonds, and *sixty grains* of Camphor, and proceeds in the manner above directed, except that the wax and oil are melted by means of a water-bath, instead of over a fire; and in this respect its directions are more judicious than those of the U. S. Pharmacopœia.

This cerate received the name by which it is commonly known from M. Goulard, by whom it was employed and recommended. It soon begins to assume a yellowish colour, and after a short time becomes so rancid as to be scarcely fit for use. Hence it should be prepared in small quantities at once. The late Mr. Jacob Bell found it more satisfactory when made with yellow wax. (*Pharm. Journ.*, March, 1859, p. 459.) Eggenfels, a German pharmaceutist, recommends the following method of proceeding to prevent its change of colour. The wax and oil are melted in a water-bath; the solution of acetate of lead, previously heated, is added in small portions successively, and the mixture well stirred, and digested for some time; a partial saponification takes place, and an emulsion afterwards; and the cerate retains its white colour. (See *Am. Journ. of Pharm.*, Sept. 1861, p. 408.) It is used chiefly in excoriations, burns, scalds, and chilblains, and in cutaneous eruptions. We have found it more effectual than any other application to blistered surfaces indisposed to heal; and, on the recommendation of the late Dr. Parrish, have used it in the following combination with advantage in various cutaneous eruptions of a local character. Take of cerate of subacetate of lead, simple cerate, each, *half an ounce;* calomel, powdered opium, each, *a drachm;* mix them. The same preparation, without the opium, was a favourite remedy with the late Prof. Wistar in similar complaints. W.

CERATUM RESINÆ. *U. S.* Unguentum Resinæ. *Br.* *Resin Cerate. Ointment of Resin. Basilicon Ointment.*

"Take of Resin *ten troyounces;* Yellow Wax *four troyounces;* Lard *sixteen troyounces.* Melt them together, strain the mixture through muslin, and stir it constantly until cool." *U. S.*

"Take of Resin, in coarse powder, *eight ounces;* Yellow Wax *four ounces;* Simple Ointment *sixteen ounces.* Melt with a gentle heat, strain the mixture while hot through flannel, and stir constantly while it cools." *Br.*

The straining is directed in consequence of the impurities which resin often contains. Resin cerate, commonly called *basilicon ointment*, is much used as a gently stimulant application to blistered surfaces, indolent ulcers, burns, scalds,

and chilblains. We have found no application more effectual in disposing the ulcers which follow burns to heal.

Off. Prep. Ceratum Sabinæ, *U. S.;* Linimentum Terebinthinæ, *Br.* W.

CERATUM RESINÆ COMPOSITUM. *U. S. Compound Resin Cerate.*

"Take of Resin, Suet, Yellow Wax, each, *twelve troyounces;* Turpentine *six troyounces;* Flaxseed Oil *seven troyounces.* Melt them together, strain the mixture through muslin, and stir it constantly until cool." *U. S.*

This is somewhat more stimulating than the preceding, but is applicable to similar purposes, particularly to the treatment of indolent ulcers. Under the name of *Deshler's salve*, it is popularly employed in some parts of the United States. It should be kept well protected from the air, in consequence of its liability when exposed to acquire a tough consistence. W.

CERATUM SABINÆ. *U. S.* UNGUENTUM SABINÆ. *Br. Savine Cerate. Ointment of Savine.*

"Take of Savine, in fine powder, *three troyounces;* Resin Cerate *twelve troyounces;* Ether *a sufficient quantity.* Moisten the Savine with Ether, pack it firmly in a cylindrical percolator, and pour on Ether until the filtered liquid passes nearly colourless. Evaporate this spontaneously to the consistence of syrup, add the concentrated liquid to the Resin Cerate, softened by a gentle heat, and mix them thoroughly." *U. S.*

"Take of Fresh Savine Tops, bruised, *eight ounces;* White Wax *three ounces;* Prepared Lard *sixteen ounces.* Melt the Lard and the Wax together on a water-bath, add the Savine, and digest for twenty minutes. Then remove the mixture, and express through calico." *Br.*

As the savine used in this country is generally brought from Europe in the dried state, we are compelled to resort to a mode of preparing the cerate different from that usually employed in Europe. In the Pharmacopœia of 1850, the dried savine was simply mixed,in powder, with resin cerate previously softened; and the proportion used was one part of the powder to six parts of the cerate. Nor did we find the preparation thus made to be "intolerably acrid and almost caustic," as Dr. Duncan described it. On the contrary, it answered very well the purpose for which it was used, that of maintaining the discharge from blistered surfaces. The process, however, of the present edition of the Pharmacopœia is certainly more elegant than the former, and probably, if well executed, will yield a more effective product; as the active matter is extracted by the ether, and must operate more energetically than while entangled in the inert matter of the leaves. The only objection to it is its expensiveness. A cerate, prepared in the same manner as the former cerate, from the leaves of the red cedar (*Juniperus Virginiana*), is sometimes substituted for that of savine, but is less efficient. Prepared according to the process of the *British* Pharmacopœia, savine cerate has a fine deep-green colour, and the odour of the leaves. It should be kept in closely covered vessels.

Savine cerate is preferable to the ointment of Spanish flies as a dressing for perpetual blisters, from the circumstance that it has no tendency to produce strangury. The white coating which forms, during its use, upon the blistered surface should be occasionally removed, as it prevents the contact of the cerate. It is sometimes applied to seton cords, to increase the discharge. W.

CERATUM SAPONIS. *U. S. Soap Cerate.*

"Take of Soap Plaster *two troyounces;* White Wax *two troyounces and a half;* Olive Oil *four troyounces.* Melt together the Plaster and Wax, add the Oil, and, after continuing the heat a short time, stir the mixture until cool." *U. S.*

This is a much neater preparation than that of the Pharmacopœia of 1850, which was made by boiling the solution of subacetate of lead with soap, and then, after concentration, adding the wax and oil melted together; nor is there any reason to suppose that it is less efficient. Soap cerate is thought to be cooling

and sedative; and is used in scrofulous swellings and other instances of chronic external inflammation. It was formerly employed by Mr. Pott as a dressing for fractured limbs; but answers no other purpose in these cases than to yield mechanical support. W.

CERATUM ZINCI CARBONATIS. *U.S.* *Cerate of Carbonate of Zinc.*

"Take of Precipitated Carbonate of Zinc *two troyounces;* Ointment of Lard *ten troyounces.* Mix them." *U. S.*

This preparation is an imitation of the cerate recommended by Turner, and is intended as a substitute for the former Ceratum Zinci Carbonatis and more recent Ceratum Calaminæ of the U. S. Pharmacopœia, as more reliable, in consequence of the frequent falsification of calamine. It is mildly astringent, and is used in excoriations and superficial ulcerations, produced by the chafing of the skin, irritating secretions, burns, or other causes.* W.

CHARTÆ.

Papers.

This class of preparations has been made officinal by the adoption, in the British Pharmacopœia, of the *Charta Epispastica*, which, though the only one at present recognised in Great Britain, will probably in time be followed by others; as external applications of this kind are often very convenient. In the present French Codex there are not less than five of these papers, placed under the heading of *Papiers Emplastiques;* of which the Charta Epispastica, named *Papier Epispastique*, is one. Of this the British preparation is a close imitation.

CHARTA EPISPASTICA. *Br. Blistering Paper.*

"Take of White Wax *four ounces;* Spermaceti *one and a half ounce;* Olive Oil *two fluidounces;* Resin *three quarters of an ounce;* Canada Balsam *one quarter of an ounce;* Cantharides, in powder, *one ounce;* Distilled Water *six fluidounces.* Digest all the ingredients, excepting the Canada Balsam, in a water-bath for two hours, stirring them constantly; then strain, and separate the plaster from the watery liquid. Mix the Canada Balsam with the plaster, melted in a shallow vessel, and pass strips of paper over the surface of the hot liquid, so that one surface of the paper shall receive a thin coating of the plaster. It may be convenient to employ paper ruled so as to indicate divisions each of which is one square inch." *Br.* The weights employed in this process are avoirdupois, and the measures Imperial.

This is intended as a convenient substitute for the common blistering plaster, and, if equally effectual, will be frequently preferred, from being already spread, as well as for its greater cleanliness and facility of application. The proportion of flies, however, is much less, being only 1 to $8\frac{1}{2}$ of the other ingredients, while in the "Cantharides Plaster" it is 12 to $16\frac{1}{2}$. The inference from this would be that it must be very greatly inferior in blistering power, and consequently less certain; but this is a point which must be determined by experience; and it is said that, when properly applied, so as to ensure close adhesion to the skin, it is not less efficient than the British plaster, the *Cerate of Cantharides* of the U. S. Pharmacopœia. (*Med. Times and Gaz.*, March, 1867, p. 284.)

* *Ceratum Calaminæ.* U. S. 1850. *Turner's Cerate.* Though abandoned as an officinal preparation, from the frequent sophistication to which calamine is liable, the preparation is still considerably used, and a formula is, therefore, required. The following is the late officinal process. "Take of Prepared Calamine, Yellow Wax, each, *three ounces;* Lard *a pound.* Melt the Lard and Wax together, and when on cooling they begin to thicken, add the Calamine, and stir the mixture constantly until cool." The uses of this cerate are the same as those mentioned in the text under *Ceratum Zinci Carbonatis.*

CINCHONIA.

Preparation of Cinchonia.

CINCHONIÆ SULPHAS. *U. S.* *Sulphate of Cinchonia.*

"Take of the mother-water, remaining after the crystallization of Sulphate of Quinia, in the process for preparing that salt, *a convenient quantity;* Solution of Soda, Alcohol, Diluted Sulphuric Acid, Animal Charcoal, in fine powder, each, *a sufficient quantity.* To the mother-water add gradually, with constant stirring, Solution of Soda, until the liquid becomes alkaline. Collect on a filter the precipitate formed, wash it with water, and dry it. Then wash it with successive small portions of alcohol, to remove other alkaloids which may be present. Mix the residue with eight times its weight of water, and, having heated the mixture, add gradually Diluted Sulphuric Acid until it is saturated and becomes clear. Then boil the liquid with Animal Charcoal, filter it while hot, and set it aside to crystallize. Lastly, drain the crystals, and dry them on bibulous paper. By evaporating the mother-liquid, more crystals may be obtained." *U. S.*

Sulphate of Cinchonia is now for the first time officinally recognised, having been introduced into the U. S. Pharmacopœia at the late revision; and this recognition is certainly justified by its great importance as a medicine. In consequence of its greater solubility it remains behind in the mother-waters, when sulphate of quinia crystallizes, in the process for preparing the latter salt. To separate it from other substances contained in the mother-waters, it is decomposed by solution of soda, which is preferable to potassa, as it forms a very soluble salt with sulphuric acid, whereas the sulphate of potassa, being of difficult solubility, might fall with the precipitated cinchonia. The precipitate may be safely washed with small portions of alcohol, as the alkaloid is almost insoluble in that liquid when cold. It is next reconverted into the sulphate; and the solution, having been boiled with *unpurified* animal charcoal to decolorize it, and at the same time neutralize any possible excess of sulphuric acid which might interfere with the crystallization of the salt, is filtered while hot, and then allowed to stand. It is peculiarly important that there should be no excess of sulphuric acid while the solution is exposed to heat, as, under this influence, the alkaloid is much disposed to become uncrystallizable. Hence the advantage of using unpurified animal charcoal or bone-black, as the carbonate of lime contained in it neutralizes any excess of the acid. The sulphate of cinchonia, held in solution by the liquid while hot, is deposited by it upon cooling in crystals.

It may be prepared also by first obtaining cinchonia from one of the pale barks; treating this with water acidulated with sulphuric acid, added gradually till the alkaloid is dissolved; then boiling with purified animal charcoal, filtering the solution while hot, and setting it aside to crystallize. By alternate evaporation and crystallization all the sulphate may be obtained.

There are two sulphates of cinchonia. The officinal salt may be considered either as the neutral sulphate, consisting of one eq. of cinchonia 308, one of sulphuric acid 40, and two of water of crystallization $18 = 366$; or, according to the view of Liebig, as a *disulphate*, consisting of two eqs. of base 308, one of acid 40, and two of water. By the addition of the necessary quantity of acid, it passes into the higher sulphate (bisulphate, or neutral sulphate, according to the view that may be adopted), which is soluble in less than half its weight of water at 58°. We have always been inclined to the view which considers it as the neutral salt, and this probably now predominates with chemists, so that the salt is properly named sulphate of cinchonia in the Pharmacopœia. It crystallizes in short, oblique, shining prisms with dihedral summits, which melt at 212°, at a somewhat higher temperature lose their water of crystallization, and at a red heat are dissipated without residue. Its taste is very bitter. It is soluble in fifty-four parts of water at common temperatures, and in a smaller quantity of boiling water, and is readily dissolved by alcohol, but very sparingly by ether. The tests by which it may be known as a salt of cinchonia are mentioned

under the head of *Cinchona* in *Part* I. (*page* 300). That it is a sulphate will be shown by the white precipitate produced with its solution by chloride of calcium.*

Medical Properties and Uses. It is now pretty well determined that sulphate of cinchonia has the same remedial properties as sulphate of quinia. That it is equally efficient as an antiperiodic remedy, in a somewhat larger dose, has been established by abundant experience. (See a paper, by Dr. A. P. Turner, in the *Am. Journ of Med. Sci.*, April, 1864, p. 396.) As a tonic it may be given in the dose of a grain or two, three or four times a day; as an antiperiodic, fifteen grains to half a drachm may be given between the paroxysms. It may be taken in pill or solution. In the latter case, the solution of the salt may be aided by the addition of a little aromatic sulphuric acid, in the proportion, for example, of a minim or two drops for each grain of the salt, in a solution of eight grains to a fluidounce of water. W.

COLLODIUM.

Preparations of Collodion.

COLLODIUM. *U. S., Br. Collodion.*

"Take of Cotton, freed from impurities, *half a troyounce;* Nitrate of Potassa, in fine powder, *ten troyounces;* Sulphuric Acid *fifteen troyounces and a half;* Stronger Ether *twenty-one fluidounces;* Stronger Alcohol *a sufficient quantity.* Add the Sulphuric Acid to the Nitrate of Potassa in a glass or porcelain vessel, and stir them together until they are uniformly mixed. When the temperature of the mixture is below 122°, add the Cotton, and, by means of stout glass rods, imbue it thoroughly with the mixture. Then cover the vessel closely with a glass or porcelain lid, and allow it to stand for twenty-four hours. Transfer the Cotton to a larger vessel, and wash it, first with cold water until the washings cease to have an acid taste, and then with boiling water. Press it as dry as possible with the hand, pack it tightly in a conical percolator, and pour upon it Stronger Alcohol until the remaining water is displaced; then again press it as dry as possible with the hand. Mix the Stronger Ether with six fluidounces of Stronger Alcohol in a suitable bottle, and, having added the moist Cotton to the mixture, agitate occasionally until it is dissolved. The Cotton, prepared for solution by this formula, and dried at 212°, weighs three hundred and thirty-six grains.

"Collodion may also be made by dissolving fifty-six grains of Cotton, prepared as above, and dried at 212°, in a mixture of three fluidounces and a half of Stronger Ether and a fluidounce of Stronger Alcohol." *U. S.*

"Take of Pyroxylin *one ounce* [avoirdupois]; Ether *thirty-six fluidounces* [Imperial measure]; Rectified Spirit *twelve fluidounces* [Imp. meas.]. Mix the Ether and the Spirit, and add the Pyroxylin. Set aside for a few days, and, should there be any sediment, decant the clear solution. Keep it in a well-corked bottle." *Br.*

Collodion is a solution of freshly prepared gun cotton in ether, assisted by a little alcohol. Gun cotton was originally obtained from cotton by steeping it in nitric acid, by the action of which it is converted into an explosive compound. (See *Pyroxylin* in *Part* II.) When gun cotton is intended for solution in ether, a better preparation for this purpose is made by the process of Dr. Ellet, of South Carolina College, which consists in steeping cotton in a mixture of nitre and sulphuric acid. This mixture sets free the necessary nitric acid for effecting the change in the cotton. Gun cotton, thus prepared, more readily

* A new test, distinguishing between sulphates of quinia and cinchonia, has recently been announced by M. Palm, of Russia, in the polysulphuret of potassium prepared by boiling solution of potassa with an excess of sulphur. When a solution of this sulphuret is added to a boiling solution of sulphate of quinia, the latter, however small the quantity present, is thrown down as a red terebinthinate mass, which hardens on cooling, and then assumes the appearance of a resin; while with sulphate of cinchonia a white powder is precipitated containing sulphur. (*Journ. de Pharm.*, Mai, 1864, p. 459.)

dissolves in ether than that made by direct reaction of nitric acid; and, for that reason, the process of Dr. Ellet was adopted in the U. S. formula. The present officinal preparation is somewhat stronger than that of the Pharmacopœia of 1850, having a considerably smaller proportion of the ether and alcohol conjointly, though the proportion of alcohol is much increased. On account of the facility with which ether evaporates, it is the better menstruum for remedial purposes; but gun cotton will not dissolve in that liquid when quite pure, and the addition of a little alcohol is necessary. The existing proportion was adjusted by Dr. Squibb, who found by frequent trial some increase in the quantity of alcohol desirable; and the resulting preparation has been found to answer well in practice. The increase of alcohol, however, though the quantity directed is six times greater than before, is in reality much less than this; for the common ether directed in the formula of 1850 itself contains a very considerable proportion of alcohol, while the stronger ether now used has comparatively little. Other improvements in the process are the fixing of the temperature at which the cotton is to be introduced into the acid mixture, which was before left indefinite, and the more complete removal of water from the gun cotton by displacing it with alcohol after expression. The process is now said to work well in practice, and yields a preparation more firm and adhesive than the old formula. Gun cotton, prepared as above directed, is not liable to decomposition, but continues fit for solution in ether for a considerable time. Hence the propriety of the alternative formula, in which the gun cotton, dried at 212°, may be dissolved in a due proportion of the two menstrua. In following the U. S. process, it is necessary that the sulphuric acid be of the officinal strength.

In the British process, gun cotton, denominated pyroxylin, is directed to be dissolved in a mixture of ether and alcohol; a formula for the preparation of pyroxylin being given separately in the Pharmacopœia. It is asserted, however, that the pyroxylin made by that formula, though an excellent explosive compound, is not readily dissolved by the mixture of ether and alcohol. (*Pharm. Journ.*, March, 1864, p. 416.)

Collodion is a transparent, colourless liquid, of a syrupy consistence, and ethereal smell. When applied to a dry surface, the ether quickly evaporates, and a transparent film is left, having remarkable adhesiveness and contractility. On account of the great volatility of ether, collodion must be kept in bottles well stopped. When insecurely kept, the liquid thickens and becomes less fit for the use of the surgeon. The thickened liquid sometimes contains acicular crystals, as was first observed by Mr. Higginson, of London, and afterwards by Prof. Leidy, of this city, who examined it with the microscope.

Collodion was first applied to the purposes of surgery by Dr. J. Parker Maynard,* of Boston, when a student of medicine, in January, 1847. It is employed for holding together the edges of incised wounds, for covering ulcers or abraded surfaces with an impervious film not acted upon by water, and for encasing parts which require to be kept without relative motion. It is applied, brushed over the part, or by means of strips of muslin. In whatever way applied, the solvent quickly evaporates, and leaves the solid adhesive material. According to Lepage, gun cotton will dissolve in equal parts of ether and alcohol, forming a solution quite as adhesive as that made with ether alone. As this solution dries more slowly, it may prove preferable to the ethereal solution in certain cases. The strong contractile power of the collodion coating is an objection to it for some purposes. This property is removed, according to Mr. C. S. Rand, of Philadelphia, by dissolving first one part of gun cotton, and then one part

* Dr. Maynard recommends the following formula as the best for surgical purposes. Take of sulphuric acid of sp. gr. 1·850 *two parts*, and of nitric acid of sp. gr. 1·450 *one part*. Mix them, and, having permitted the heat to fall to about 100°, add raw cotton to saturation. Let it macerate for one or two hours; then pour off the acids, wash the cotton till the washings cease to affect litmus paper, and dry thoroughly. The gummy matter thus formed is now to be dissolved in ether of the sp. gr. about ·750, or in a mixture of three parts of pure ether and one part of alcohol of 95 per cent. Two ounces of cotton will make about a pint of collodion. (*Bost. Med. and Surg. Journ.*, Aug. 9, 1866, p. 39.)—*Note to the thirteenth edition.*

of Venice turpentine, in twenty parts of ether. To give more flexibility to the film, M. Sourisseau, of Kaiserberg, adds one part of elemi to twelve of collodion. According to Mr. Startin, of London, opacity and elasticity may be imparted at the same time, by adding from half a drachm to a drachm of lard, or some similar fatty matter, previously dissolved in ether, to an ounce of collodion. The qualities of softness and elasticity are given by combining collodion with castor oil, in the proportion of thirty parts to two, agreeably to the plan of M. Guérsant, who found it useful, thus modified, in erysipelas; and the proportion of castor oil may be increased if thought desirable. An elastic collodion, somewhat similar, in which, besides castor oil, Venice turpentine and white wax are ingredients, has been proposed by E. Lauras. (*Pharm. Journ.*, xii. 303.) A very pliable collodion may be made of thirty parts of collodion, twelve of Venice turpentine, and six of castor oil. According to MM. Cap and Garot, the most successful way for obtaining an elastic collodion is to mix two parts of glycerin with one hundred of collodion. *Glycerized collodion* is exceedingly supple, does not crack and scale off from the skin, and accommodates itself to the motions of the part. In order to imitate the colour of the skin, an ethereal tincture of turmeric or saffron may be added, so as to produce the desired tint. Dr. Meller has proposed a solution of shell-lac in highly rectified alcohol, so as to have a gelatinous consistence, as a succedaneum for collodion.

Collodion has been used with advantage by Dr. J. R. Mitchell, of Dublin, and by Dr. Aran, to form an artificial covering to ulcers of the os and cervix uteri, thereby allowing the healing process to go on underneath; by M. Wetzlar, of Aix-la-Chapelle, in chilblains; and by Dr. J. W. Freer, of Illinois, in erysipelas. According to Dr. Christen, of Prague, collodion is useful in erysipelas from local causes only, such as wounds, ulcers, burns, &c., but hurtful in the disease from an internal cause. The same writer condemns its use to prevent pitting in small-pox as positively injurious. In burns collodion has been found highly useful by several practitioners, especially in conjunction with castor oil. Its application produces sharp pain at first. It acts by affording a protective covering to the cutis, and, in superficial inflammation, probably, in part, by expelling the blood from the inflamed vessels through the contractile power of the film. This property of collodion has been taken advantage of in the treatment of chronic entropium, two cases of which, successfully treated by it, have been reported by Mr. William Batten. (*Ranking's Abstract*, no. 23, p. 134.) Dr. J. H. Claiborne has used a thick coating of collodion with decided advantage as a compressing agent for the discussion of buboes. It is said to have proved useful in phlegmasia dolens, and is asserted even to have cured a case of puerperal peritonitis, spread over the surface of the abdomen. (*Med. Times and Gaz.*, Oct. 1859, p. 342.) It sometimes causes the disappearance of nævi materni simply applied to the surface. (Dr. Wm. Badger, *Med. Record*, Oct. 1, 1868, p. 358.)

Mr. Erasmus Wilson has used collodion with decided advantage in certain diseases of the skin. In chapped nipples it has an admirable effect. When applied to ulcers, abrasions, or chaps of the skin, it requires to be diluted with ether, so as to render it nearly as limpid as water. Mr. J. H. Tucker found it useful in stopping the bleeding from leech-bites. M. Sourisseau and Mr. E. H. Durden have used it as a coating for pills, which are thereby deprived of taste; but it is questionable whether the coating would always be dissolved by the gastric liquids.

Dr. Drouet, of France, believes that collodion applied to the abdomen, if resorted to at the commencement of cholera, will arrest the disease when not of an extremely violent nature; and founds his belief upon a considerable experience with the remedy. It is peculiarly effectual in the diarrhœa preceding cholera. He mixes six parts of collodion with one part of castor oil, and, having smeared it over the abdomen, covers it with cotton. (*N. Y. Med. Journ.*, Feb. 1867, p. 388; from *Journ. de Méd. et de Chim. Pratiques.*)

Collodion has been variously medicated, and thus made the vehicle of several important medicines for external application. *Iodized collodion* has been pro-

posed by Dr. C. Fleming, for the purpose of obtaining the specific effects of iodine in a rapid manner, especially on tumours. It is made by dissolving from ten to twenty grains of iodine in a fluidounce of collodion. M. Aran has proposed a *ferruginous collodion*, made of equal parts of collodion and tincture of chloride of iron, as a remedy in erysipelas. A *caustic collodion* may be prepared by dissolving 4 parts of corrosive sublimate in 30 of collodion. Dr. Macke, of Sorau, has used this preparation for destroying nævi materni. The eschar formed is one or two lines in thickness, and separates in from three to six days, leaving but a trifling cicatrix. (See *Am. Journ. of Pharm.*, May, 1858, for formulas in which collodion is made the vehicle of iodine, belladonna, sulphur, &c.) All these medicated collodions are most conveniently applied by means of a camel's-hair brush.

Collodion has become an important agent in various photographic processes.*

Off. Prep. Collodium Flexile, *Br.* B.

COLLODIUM CUM CANTHARIDE. *U. S. Collodion with Cantharides. Cantharidal Collodion.*

"Take of Cantharides, in fine powder, *eight troyounces;* Cotton, prepared by the process for Collodion, and dry, *one hundred grains;* Stronger Ether *a pint and a half;* Stronger Alcohol *a sufficient quantity.* Introduce the Cantharides into a cylindrical percolator, and, having pressed them firmly, gradually pour on the Ether. When fifteen fluidounces have passed, set aside the liquid in a close vessel, and continue the percolation with Stronger Alcohol until half a pint more of liquid is obtained. Set this in a warm place for spontaneous evaporation, and, when it is reduced to a fluidounce, mix it with the reserved liquid. Then add the Cotton to the mixture, and agitate occasionally until it is dissolved. Lastly, keep the solution in a well-stopped bottle." *U. S.*

This was originally proposed by M. Ilisch, of St. Petersburg, Russia, and was introduced into our Pharmacopœia at the late revision. The flies are exhausted successively by ether and alcohol, the ethereal solution is set aside, the alcoholic is allowed to evaporate till reduced from eight fluidounces to one, and the two liquids being then mixed are used as the menstruum for gun cotton. But, considering the character of the menstruum, it appears to us that it must frequently fail to dissolve the cotton; as a larger proportion of alcohol is required for the purpose than will remain when the tincture has been reduced to one fluidounce by evaporation. Had common ether, which always contains a considerable proportion of alcohol, been adopted instead of stronger ether, there would probably have been enough alcohol to render the process effectual, and economy would at the same time have been consulted. Should, therefore, the formula fail in the hands of the operator, we would suggest the substitution of the common ether. The original process of M. Ilisch was to exhaust, by percolation, a pound of cantharides, with a mixture consisting of a pound of ether and three ounces of acetic ether; and in two ounces of this liquid to dissolve 25 grains of gun cotton. Professor Procter states that it has been found more advantageous to exhaust the flies with ether, distil off the ether, and mix the oily residue with collodion already prepared of the proper consistence (*Am. Journ. of Pharm.*, xxiv. 303); and this is probably a better formula than the officinal. Mr. Charles S. Rand, in

* *Silk Collodion.* M. Persoz, the younger, prepares a collodion from silk by bringing it to the condition of the material from which the worm spins its thread. This he does by dissolving silk in a solution of chloride of zinc, and then separating the solvent by means of dialysis. The solution, diluted with water to the consistence of collodion, is put into a gutta-percha vessel having a parchment bottom, which is made to rest on a surface of water. The chloride passes through the parchment, leaving the silk substance in a soft fibreless state. The chloride solution, before being used, should be heated with a little oxide of zinc, to neutralize any excess of acid, and then filtered through fine linen to separate the residual oxide. For prompt action, the chloride should be kept warm. Its separation from the silk requires a few days. The material thus obtained is said to be applicable to photographic purposes. Before it could be used as collodion, it would be necessary to dissolve it in a volatile liquid, which would evaporate spontaneously on application to the surface. (See *Am. Journ. of Pharm.*, March, 1867, p. 182.)—*Note to the thirteenth edition.*

a communication to the *American Journal of Pharmacy* (xxii. 18), states that Ilisch's preparation, made with double the proportion of ether, vesicates equally well, and proposes the addition of about 1 per cent. of Venice turpentine, which he has found to prevent the disagreeable and sometimes painful contraction of the collodion upon drying. The preparation may be kept indefinitely, in an opaque glass-stoppered bottle, without change; but, on exposure to the light, the greenish colouring matter of the flies bleaches, and the liquid becomes yellowish.

Cantharidal collodion is a very convenient epispastic remedy. It may be applied to the surface by means of a camel's-hair brush, and, after the evaporation of the ether, which takes place in less than a minute, may be reapplied if the surface should not be well covered. It produces a blister in about the same time as the ordinary cerate, and has the advantages that it is applied with greater facility, is better adapted to cover uneven surfaces, and retains its place more certainly. According to Mr. Rand, if the evaporation of the ether be restrained by a piece of oiled silk immediately after its application, it will act much more speedily. W.

COLLODIUM FLEXILE. *Br. Flexible Collodion.*

"Take of Collodion *six fluidounces* [Imperial measure]; Canada Balsam *one hundred and twenty grains;* Castor Oil *one fluidrachm* [Imp. meas.]. Mix, and keep in a well-corked bottle." *Br.*

This new officinal of the British Pharmacopœia has been introduced to meet a want in the use of collodion which the practitioner often feels, the methods of meeting which have been fully considered in the article on Collodion. (See *pages* 1086–7.) W.

CONFECTIONES. *U. S., Br.*

Confections.

Under the general title of Confections, the Pharmacopœias include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. The old division into Conserves and Electuaries has been abandoned; but, as there is some ground for the distinction, we shall make a few general remarks upon each division, before proceeding to the consideration of the individual preparations.

Conserves consist of recent vegetable substances and refined sugar beaten into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now retained are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be reduced to a fine powder by pounding and sifting, as otherwise it will not mix uniformly with the other ingredients.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made in the shops, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for officinal direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary be found, after having been kept for a short

time, to swell up and emit gas, it should be beaten over again in a mortar, so that any portion of the sugar which may have crystallized may be again accurately incorporated with the other ingredients. Should it, on the contrary, become dry and hard from the mutual reaction of its constituents, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup, and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose; but its taste might be objectionable. Some employ honey, but this is not always acceptable to the stomach. Glycerin might sometimes be used with advantage. W.

CONFECTIO AROMATICA. *U. S. Aromatic Confection.*

"Take of Aromatic Powder *four troyounces;* Clarified Honey *four troyounces*, or *a sufficient quantity.* Rub the Aromatic Powder with Clarified Honey until a uniform mass is obtained of the proper consistence." *U. S.*

The aromatic confection has been abandoned in the Br. Pharmacopœia, probably because readily prepared extemporaneously. It affords, nevertheless, a convenient means of administering the spices contained in it, and an agreeable vehicle for other medicines. The present U. S. formula differs favourably from that of 1850 in the omission of the saffron; and the place of the syrup of orange peel has been economically supplied by using a larger proportion of honey. The confection is given in debilitated states of the stomach. The dose is from ten to sixty grains. W.

CONFECTIO AURANTII CORTICIS. *U. S. Confection of Orange Peel.*

"Take of Sweet Orange Peel, recently separated from the fruit by grating, *twelve troyounces;* Sugar [refined] *thirty-six troyounces.* Beat the Orange Peel with the Sugar, gradually added, until they are thoroughly mixed." *U. S.*

This confection, like the preceding, has been dropped in the recent consolidation of the British Pharmacopœias. It is sometimes used as a grateful aromatic vehicle or adjunct of tonic and purgative powders. W.

CONFECTIO OPII. *U. S., Br. Confection of Opium.*

"Take of Opium, in fine powder, *two hundred and seventy grains;* Aromatic Powder *six troyounces;* Clarified Honey *fourteen troyounces.* Rub the Opium with the Aromatic Powder, then add the Honey, and beat the whole together until thoroughly mixed." *U. S.*

"Take of Compound Powder of Opium *one hundred and ninety-two grains;* Syrup *one fluidounce* [Imperial measure]. Mix." *Br.*

This confection was intended as a substitute for those exceedingly complex and unscientific preparations, formerly known by the names of *theriaca* and *mithridate*, which have been expelled from modern pharmacy. It was an officinal of the London and Edinburgh Colleges; and, after having been discarded in the first British Pharmacopœia, has been adopted in the present edition. The preparation is a combination of opium with spices, which render it more stimulant, and more grateful to a debilitated stomach. It may be given in atonic gout, flatulent colic, diarrhœa unattended with inflammation, and other diseases requiring the use of a stimulant narcotic. Added to Peruvian bark or sulphate of quinia, it increases the efficacy of this remedy in obstinate cases of intermittent fever. One grain of opium is contained in about thirty-six grains of the U. S. confection, and in about forty grains of the British. W.

CONFECTIO PIPERIS. *Br. Confection of Black Pepper.*

"Take of Black Pepper, in fine powder, *two ounces;* Caraway Fruit, in fine powder, *three ounces;* Clarified Honey *fifteen ounces.* Rub them well together in a mortar." *Br.*

This preparation was intended as a substitute for *Ward's paste*, which ac-

quired some reputation in Great Britain as a remedy in piles and ulcers of the rectum. To do good, it must be continued, according to Mr. Brodie, for two three, or four months. The dose is from one to two drachms repeated two or three times a day. Its stimulating properties render it inapplicable to cases attended with much inflammation. W.

CONFECTIO ROSÆ. *U. S.* Confectio Rosæ Gallicæ. *Br.* *Confection of Rose. Confection of Roses.*

"Take of Red Rose, in fine powder, *four troyounces;* Sugar [refined], in fine powder, *thirty troyounces;* Clarified Honey *six troyounces;* Rose Water *eight fluidounces.* Rub the Rose with the Rose Water heated to 150°; then gradually add the Sugar and Honey, and beat the whole together until thoroughly mixed." *U. S.*

"Take of Fresh Red-Rose Petals *one pound;* Refined Sugar *three pounds.* Beat the Petals to a pulp in a stone mortar; add the Sugar, and rub them well together." *Br.*

In the British process the unblown petals only are used, and these should be deprived of their claws; in other words, the rose-buds should be cut off a short distance above their base, and the lower portion rejected. In the last three editions of the U. S. Pharmacopœia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex. We have been informed, however, that much of the confection of roses made in Philadelphia is prepared from the fresh petals of the hundred-leaved rose and others, by beating them into a pulp with sugar, as in the British process. An excuse for this deviation from the officinal formula is, that the confection thus made has greater adhesiveness than the officinal, and is therefore better fitted for the formation of pills.

This confection is slightly astringent, but is almost exclusively used as a vehicle of other medicines, or to impart consistence to the pilular mass.

Off. Prep. Pilula Aloes Barbadensis, *Br.;* Pil. Aloes et Assafœtidæ, *Br.;* Pil. Aloes et Ferri, *Br.;* Pil. Aloes et Myrrhæ, *Br.;* Pil. Aloes Socotrinæ, *Br.;* Pil. Ferri Carbonatis, *Br.;* Pilulæ Hydrargyri; Pil. Plumbi cum Opio, *Br.* W

CONFECTIO ROSÆ CANINÆ. *Br.* *Confection of Hips.*

"Take of Hips deprived of their seeds *one pound;* Refined Sugar *two pounds.* Beat the Hips to a pulp in a stone mortar, and rub the pulp through a sieve, then add the Sugar, and rub them well together." *Br.*

This preparation is acidulous and refrigerant, and is used in Europe for forming more active medicines into pills and electuaries.

Off. Prep. Pilula Quiniæ, *Br.* W.

CONFECTIO SCAMMONII. *Br.* *Confection of Scammony.*

"Take of Scammony, in fine powder, *three ounces;* Ginger, in fine powder, *one ounce and a half;* Oil of Caraway *one fluidrachm;* Oil of Cloves *half a fluidrachm;* Syrup *three fluidounces;* Clarified Honey *one ounce and a half.* Rub the powders with the Syrup and the Honey into a uniform mass, then add the Oils and mix." *Br.* The ounce used in this process is the avoirdupois ounce.

The confection is actively cathartic in the dose of half a drachm or a drachm; but is very little used. The British Pharmacopœia now directs scammony alone in its formula without the alternative of the resin given in the first edition. This is a decided improvement. As this drug is generally found in the market, it has but little more than half the strength of the resin. It is true that the purest and best scammony is much stronger than this, yet it is decidedly weaker than its resin, and the Pharmacopœia itself describes it as containing only from 80 to 90 per cent. of this ingredient. It appears to have been a strange want of precision thus to confound the two, as if they were to be given in the same dose. W.

CONFECTIO SENNÆ. *U.S., Br. Confection of Senna. Lenitive Electuary.*

"Take of Senna, in fine powder, *eight troyounces;* Coriander, in fine powder, *four troyounces;* Purging Cassia, finely bruised, *sixteen troyounces;* Tamarind *ten troyounces;* Prune, sliced, *seven troyounces;* Fig, bruised, *twelve troyounces;* Sugar, in coarse powder, *thirty troyounces;* Water *a sufficient quantity.* Digest, in a close vessel, by means of a water-bath, the Purging Cassia, Tamarind, Prune, and Fig in three pints of Water for three hours. Separate the coarser portions with the hand, and pass the pulpy mass, by rubbing, first through a coarse hair sieve, and then through a fine one, or a muslin cloth. Mix the residue with a pint of Water, and, having digested the mixture for a short time, treat it as before, and add the product to the pulpy liquid first obtained. Then, by means of a water-bath, dissolve the Sugar in the pulpy liquid, and evaporate the whole until it weighs ninety-six troyounces, or until it has been brought to the consistence of honey. Lastly, add the Senna and Coriander, and incorporate them thoroughly with the other ingredients while yet warm." *U. S.*

"Take of Senna, in fine powder, *seven ounces;* Coriander Fruit, in fine powder, *three ounces;* Figs *twelve ounces;* Tamarind *nine ounces;* Cassia Pulp *nine ounces;* Prunes *six ounces;* Extract of Liquorice *three-quarters of an ounce;* Refined Sugar *thirty ounces;* Distilled Water *a sufficiency.* Boil the Figs and Prunes gently with twenty-four [fluid]ounces of Distilled Water in a covered vessel for four hours; then, having added more Distilled Water to make up the quantity to its original volume, mix the Tamarind and Cassia Pulp, digest for two hours, and rub the softened pulp of the fruits through a hair sieve, rejecting the seeds and other hard parts. To the pulped product add the Sugar and Extract of Liquorice and dissolve them with a gentle heat; while the mixture is still warm, add to it gradually the mixed Senna and Coriander powders, and mix the whole thoroughly, making the weight of the resulting Confection seventy-five ounces either by evaporation or by the addition of more Distilled Water." *Br.* The ounce employed in the British process is the avoirdupois ounce.

The confection of senna, when correctly made, is an elegant preparation, and keeps well if properly secured. The present U. S. process differs from the old in preparing the pulps, as suggested in former editions of this Dispensatory, instead of taking them already prepared; and this is no doubt the best plan. The only material difference is the omission of the liquorice root in the present formula, and this is of no other consequence than that its taste may be missed in the confection. It is not uncommon to omit the cassia pulp in the preparation of the confection, as the pods are not always to be found in the market. But, as this is next to senna the most active ingredient, the omission is to be regretted; and there is no doubt that a steady demand for the fruit would be met by an abundant supply from the West Indies.*

This is one of our best and most pleasant laxatives, being admirably adapted to cases of habitual costiveness, especially in pregnant women and persons affected with piles. It is also very useful in the constipation which is apt to attend convalescence from fevers and other acute diseases. The mean dose is two drachms, to be taken at bedtime. W.

CONFECTIO SULPHURIS. *Br. Confection of Sulphur.*

"Take of Sublimed Sulphur *four ounces* [avoirdupois]; Acid Tartrate of Potash *one ounce* [avoird.]; Syrup of Orange Peel *four fluidounces.* Rub them well together." *Br.*

* Senna has been variously prepared to obtain the effects of this confection, in a more agreeable, or less complex form. Thus, under the name of *medicated prunes* a confection is prepared by mixing prunes with concentrated infusion of senna, and evaporating with a gentle heat to the proper consistence, a little sugar being added to improve the flavour; *senna figs* appear to be made by slitting figs, and impregnating the interior parts with extract or powder of senna; and *senna paste* consists of figs and powdered senna, beaten thoroughly together to the consistence of a confection, and then covered with granulated sugar. (*Note to the eleventh edition.*)

This is merely a mode of administering the two laxatives, sulphur and bitartrate of potassa; and the relative proportion of the latter is so small that it can have little effect. The dose is from one to two drachms or more. W.

CONFECTIO TEREBINTHINÆ. *Br.* *Confection of Turpentine.*

"Take of Oil of Turpentine *one fluidounce;* Liquorice Root, in powder, *one ounce* [avoirdupois]; Clarified Honey *two ounces* [avoird.]. Rub the Oil of Turpentine with the Liquorice, add the Honey, and mix to a uniform consistence." *Br.*

Confections might be multiplied indefinitely upon the principle which appears to have been adopted here, that, namely, of giving a convenient formula for the administration of medicines. The effects of this confection are those only of the oil of turpentine. The dose may be from a scruple to a drachm. W.

CUPRUM.

Preparation of Copper.

CUPRUM AMMONIATUM. *U.S.* *Ammoniated Copper.*

"Take of Sulphate of Copper *half a troyounce;* Carbonate of Ammonia *three hundred and sixty grains.* Rub them together in a glass mortar until effervescence ceases. Then wrap the Ammoniated Copper in bibulous paper, dry it with a gentle heat, and keep it in a well-stopped glass bottle." *U. S.*

When the two salts above mentioned are rubbed together, a reaction takes place between them, attended with the extrication of the water of crystallization of the sulphate of copper, which renders the mass moist, and with the simultaneous escape of carbonic acid gas from the carbonate (sesquicarbonate) of ammonia, which occasions an effervescence. The colour is at the same time altered, passing from the light blue of the powdered sulphate of copper to a beautiful deep azure. The nature of the chemical changes which take place is not precisely known. One of the views which have been taken is, that the blue vitriol parts with a portion of its acid to the ammonia of the carbonate, thus forming a subsulphate of copper and sulphate of ammonia, which are either mixed together, or chemically united in the form of a double salt, the sulphate of copper and ammonia. According to Phillips, the sulphuric acid of the sulphate of copper unites with the ammonia of a portion of the sesquicarbonate of ammonia; while the carbonic acid of the decomposed sesquicarbonate partly escapes, and partly combines with the oxide of copper; so that the resulting preparation consists of sulphate of ammonia, carbonate of copper, and undecomposed sesquicarbonate of ammonia. It is highly probable that Cuprum Ammoniatum, independently of the excess of sesquicarbonate of ammonia which it may contain, is identical with the crystallized salt obtained by dropping a solution of pure ammonia into a solution of sulphate of copper till the subsalt first thrown down is dissolved, then concentrating, and precipitating by alcohol. Now, from the analysis of this salt by Berzelius, it appears to contain one equivalent of sulphuric acid, one of oxide of copper, two of ammonia, and one of water, which may be supposed to be combined in the form of a double salt—the *cupro-sulphate of ammonia*—consisting of one eq. of sulphate of ammonia, one of cuprate of ammonia, in which the oxide of copper acts the part of an acid, and one of water of crystallization ($NH_3,SO_3 + NH_3,CuO + HO$). But as half an ounce of sulphate of copper would require for such a result somewhat less than the same weight of sesquicarbonate of ammonia, there must be a considerable excess of the latter salt, unless dissipated in the drying process. In the uncertainty which exists as to the precise nature of the preparation, the name of *ammoniated copper* appears to be the most appropriate as a pharmaceutical title.

This salt has a beautiful deep azure-blue colour, a strong ammoniacal odour, and a styptic, metallic taste. It is soluble in water, and the solution has an alkaline reaction on vegetable colours; but, unless there is excess of sesquicarbonate of ammonia, the solution deposits subsulphate of copper if much diluted. When

exposed to the air it parts with ammonia, and is said to be ultimately converted into sulphate of ammonia and carbonate of copper. This change is apt to occur, to a greater or less extent, while it is drying. It should not, therefore, be prepared in large quantities at a time, and should be kept in well-closed bottles. By heat the whole of it is dissipated, except the oxide of copper. Arsenious acid precipitates a green arsenite of copper from its solution. Potassa, soda, lime-water, and the acids are incompatible with it.

Medical Properties and Uses. Ammoniated copper is tonic, and is thought to exercise an influence over the nervous system which renders it antispasmodic. It has been much employed in epilepsy, in which it was recommended by Cullen. There is good reason to believe that it has occasionally effected cures; but like all other remedies in that complaint it very frequently fails. It has also been used in chorea, hysteria, and worms; and by Swediaur as an injection in gonorrhœa and leucorrhœa. In overdoses it produces vomiting, and the poisonous effects which result from the other preparations of copper. (See *Cuprum.*) It is said, however, to be less apt to excite nausea. The dose is a quarter or half a grain, repeated twice a day, and gradually increased to four or five grains. It may be given in pill or solution. The medicine should not be very long continued without interruption; according to Cullen, not longer than a month. It has been discarded by the British Council; but surely it must be still used in Great Britain to an extent which would render expedient an official regulation of the mode of preparing it. W.

DECOCTA.

Decoctions.

Decoctions are solutions of vegetable principles, obtained by boiling the substances containing these principles in water. Vegetables generally yield their soluble ingredients more readily, and in larger proportion, to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapour over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a general rule, be long continued; as the ingredients of the vegetable are apt to react on each other, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh, should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fibre. Should the physician not happen to prescribe this preliminary comminution, the apothecary should nevertheless not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavourable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble, or but slightly soluble in cool water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure, the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process, more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place, and the liquid is rendered turbid. When the active principle is thus dissolved in excess, the decoction should always be strained while hot; so that the matter which separates on cooling, may be mixed again with the fluid by agitation at the time of administering the remedy.

In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for

extracting their virtues; and, should any one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a general rule, glass or earthenware vessels should be preferred; as those made of metal are sometimes corroded by the ingredients of the decoction, which thus becomes contaminated. Vessels of clean cast-iron or common tin, or of block tin, are preferable to those of copper, brass, or zinc; but iron pots should not be used when astringent vegetables are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, in warm weather, for a longer period than forty-eight hours.

The new directions for decoctions in the U. S. Pharmacopœia meet, as a general rule, all the requisitions above mentioned, and are remarkably neat and precise. It is, however, to be feared that, in the aim at uniformity, in itself very desirable, the peculiar qualities of the substances submitted to the process, requiring peculiar treatment, have, in some instances, been overlooked. The directions, moreover, are adapted to the wants of the pharmaceutist, and cannot always be conveniently carried out in families, to whom the preparation of this class of medicines must often be confided. In such instances, it might be better for the physician simply to order the drug to be boiled in a covered vessel, for a certain length of time, or down to a certain amount, in a given quantity of water; as directed in former editions of the U. S. Pharmacopœia. Our list of officinal decoctions had been on former occasions so well freed from useless formulas that, at the recent revision, there did not seem to be sufficient cause to dismiss a single one from the list; while, in the British Pharmacopœia, not less than 17 of this class, formerly directed by the three Colleges, were discarded. These were the Decoctions of *Pipsissewa*, *Pale* and *Red Cinchona*, *Quince Seed*, *Bittersweet*, *Galls*, *Pomegranate Rind*, *Guaiacum Wood*, *Mezereon*, *Myrrh*, *Seneka*, *Tormentil*, *Elm Bark*, and *Uva Ursi*, and the Compound Decoctions of *Barley*, *Flaxseed*, and *Broom*. Of these the Decoction of Elm Bark has been restored in the present edition. W.

DECOCTUM ALOES COMPOSITUM. *Br. Compound Decoction of Aloes.*

"Take of Extract of Socotrine Aloes *one hundred and twenty grains;* Myrrh, Saffron, of each, *ninety grains;* Carbonate of Potash *sixty grains;* Extract of Liquorice *one ounce* [avoirdupois]; Compound Tincture of Cardamoms *eight fluidounces;* Distilled Water *a sufficiency.* Reduce the Extract of Aloes and Myrrh to coarse powder, and put them together with the Carbonate of Potash and Extract of Liquorice into a suitable covered vessel with a pint [Imperial measure] of Distilled Water; boil gently for five minutes, then add the Saffron. Let the vessel with its contents cool, then add the Tincture of Cardamoms, and, covering the vessel closely, allow the ingredients to macerate for two hours; finally strain through flannel, pouring as much Distilled Water over the contents of the strainer as will make the strained product measure thirty fluidounces." *Br.*

This is essentially the former process of the British Colleges. The direction is properly given to rub the aloes, myrrh, and carbonate of potassa together before the addition of the other ingredients. The effect of the alkaline carbonate is, by combining with the resin of the myrrh, and the insoluble portion (apotheme of *Berzelius*) of the aloes, to render them more soluble in water, while the liquorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition. This decoction is said not to filter clear when first made, but, if kept for some time, to deposit insoluble matter, and then to become bright and clear on filtering. (*Pharm. Journ.*, xiv. 491.)

Long boiling impairs the purgative property of aloes; and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly

qualify its operation, and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself, and not so liable to produce or aggravate hemorrhoidal disease. At the same time it is more tonic and cordial from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the carbonate of potassa. It is given as a gentle cathartic, tonic, and emmenagogue; and is especially useful in dyspepsia, habitual constipation, and those complicated cases in which suppressed or retained menstruation is connected with enfeebled digestion and a languid state of the bowels. The dose is from half a fluidounce to two fluidounces. The decoction should not be combined in prescription with acids, acidulous salts, or other saline bodies which are incompatible with the alkaline carbonate. W.

DECOCTUM CETRARIÆ. *U. S.*, *Br.* *Decoction of Iceland Moss.*

"Take of Iceland Moss *half a troyounce;* Water *a sufficient quantity.* Boil the Iceland Moss in a pint of Water for fifteen minutes, strain with compression, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Iceland Moss *one ounce* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Wash the Moss in cold water, to remove impurities; boil it with the Distilled Water for ten minutes in a covered vessel, and strain, with gentle pressure, while hot; then pour Distilled Water over the contents of the strainer until the strained product measures a pint [Imp. meas.]." *Br.*

The directions of the U. S. Pharmacopœia of 1850 were to boil *half an ounce* of the Moss with *a pint and a half* of Water down to a pint, and to strain with compression; and this process is preferable when the object is to extract not only the bitter principle, but also the whole of the demulcent and nutritive matter. As the bitter principle is dissolved along with the starch-like matter of the moss, this decoction unites an unpleasant flavour to its demulcent properties; but the plan which has been proposed of first extracting the bitterness by maceration in water, or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, is inadmissible; as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. (See *Cetraria.*) A pint of the decoction may be taken during the day. W.

DECOCTUM CHIMAPHILÆ. *U. S.* *Decoction of Pipsissewa. Decoction of Winter Green.*

"Take of Pipsissewa, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Pipsissewa in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

Though, in our estimation, a very valuable medicine, this decoction does not appear to be much used abroad, and has been omitted in the British Pharmacopœia. The U. S. directions of 1850 were to boil an ounce of the bruised leaves with a pint and a half of water to a pint, and strain; and, having been much in the habit of using the decoction thus prepared, and found it to answer our purposes well, we must confess a wish that the same direction in reference to the amount of boiling had been retained.

The medical properties and uses of pipsissewa have been detailed under the head of Chimaphila. One pint of the decoction may be given in the course of twenty-four hours. W.

DECOCTUM CINCHONÆ FLAVÆ. *U. S.*, *Br.* *Decoction of Yellow Cinchona. Decoction of Yellow Bark.*

"Take of Yellow Cinchona, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Yellow Cinchona in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Yellow-Cinchona Bark, in coarse powder, *one ounce and a quarter* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel. Strain the decoction, when cold, and pour as much

distilled water over the contents of the strainer as will make the strained product measure one pint [Imp. meas.]." *Br.* W.

DECOCTUM CINCHONÆ RUBRÆ. *U.S.* *Decoction of Red Cinchona. Decoction of Red Bark.*

"Take of Red Cinchona, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Red Cinchona in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

The British Council has discarded this decoction, and there is no necessity for making distinct formulas for the several varieties. It would, we think, be better to have but one formula for all the varieties, with the general name of Decoctum Cinchonæ, and to leave to the physician the special designation.

The virtues of Peruvian bark, though extracted more rapidly by decoction than by infusion, are materially impaired by long boiling, in consequence of the changes effected in its constituents, either by their mutual reaction, or by the agency of atmospheric oxygen, or by both causes united. To prevent this result, the process should be performed in a covered vessel, and continued only ten or at the furthest fifteen minutes. But, even with these precautions, a considerable precipitate takes place in the decoction upon cooling, which is thus rendered turbid. According to Pelletier, besides the kinates of cinchonia and quinia, the water dissolves gum, starch, yellow colouring matter, kinate of lime, tannin, and a portion of cinchonic red, with a minute quantity of fatty matter. But the tannin and starch, at the boiling temperature, unite to form a compound insoluble in cold water; and, when the decoction is allowed to cool, this compound is precipitated, together with a portion of the cinchonic red and fatty matter, which carry with them also a considerable quantity of the alkaline principles of the bark. (*Journ. de Pharm.*, vii. 119.) Hence, the decoction is ordered to be strained while hot, so that the portion of active matter precipitated may be mingled by agitation with the liquor, and not be lost. Pelletier recommends that a larger proportion of water, sufficient to retain the alkaloid in solution, be employed, that the decoction be filtered when cold, and then sufficiently concentrated by evaporation. A better mode is to add to the liquid some acid which may form with the quinia and cinchonia compounds more soluble than the native salts. Lemon juice has been long employed as a useful addition to the decoction of cinchona, and we can now understand the manner in which it acts. Sulphuric acid in excess answers the same purpose. By acidulating the pint of water employed in preparing the decoction with a fluidrachm of the aromatic or diluted sulphuric acid, we shall probably enable the menstruum to extract all the virtues of the bark. The propriety of such an addition is confirmed by the experiments of *MM. Henry, jun.*, and *Plisson*, who ascertained that portions of the alkaloids exist in the bark connected with the colouring matter in the form of insoluble compounds, and that it is impossible, therefore, completely to exhaust the bark by water alone. There may, however, be some diversity of action in the different salts of quinia and cinchonia; and the native kinates may, under certain circumstances, be most efficient.

Numerous substances produce precipitates with this decoction; but comparatively few affect its activity as a medicine. (See *Infusum Cinchonæ.*) Tannic acid and the substances containing it should be excluded from the decoction; as it forms salts with the alkaline principles of the bark, which are either insoluble or but slightly soluble in water. The alkalies, alkaline earths, and salifiable bases generally should also be excluded; because, uniting with the kinic acid, they precipitate the alkaloids.

The dose of the decoction is two fluidounces, to be repeated more or less frequently according to circumstances. Two drachms of orange peel, added to the decoction while still boiling hot, improve its flavour, and render it more acceptable to the stomach. W.

DECOCTUM CORNÛS FLORIDÆ. *U. S.* *Decoction of Dogwood.*

"Take of Dogwood, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Dogwood in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

This decoction has been proposed as a substitute for that of Peruvian bark; but, though possessed of analogous properties, it is much inferior in efficacy, and is not likely to be extensively employed so long as the Peruvian tonic is attainable. The dose is two fluidounces. W.

DECOCTUM DULCAMARÆ. *U. S.* *Decoction of Bittersweet.*

"Take of Bittersweet, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Bittersweet in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

This has been omitted in the British Pharmacopœia, and an infusion substituted; but why, we are at a loss to say; for there is no reason to suppose that the virtues of bittersweet are materially impaired by boiling; and the twigs, having a somewhat ligneous texture, require a more thorough operation of the menstruum than many other substances. Indeed, this is one of the decoctions in which we are disposed to prefer the formula of 1850, which directed that an ounce of the twigs should be boiled with a pint and a half of water to a pint.

The properties and uses of this decoction have been already detailed under the head of *Dulcamara.* The dose is from one to two fluidounces three or four times a day, or more frequently. W.

DECOCTUM GRANATI RADICIS. *Br.* *Decoction of Pomegranate Root.*

"Take of Pomegranate Root Bark, sliced, *two ounces* [avoirdupois]; Distilled Water *two pints* [Imperial measure]. Boil down to a pint [Imp. meas.], and strain, making the strained product up to a pint [Imp. meas.], if necessary by pouring distilled water over the contents of the strainer." *Br.*

For the uses and dose of this decoction, see *Granati Radicis Cortex.* W.

DECOCTUM HÆMATOXYLI. *U. S., Br.* *Decoction of Logwood.*

"Take of Logwood, rasped, *a troyounce;* Water *a sufficient quantity.* Boil the Logwood in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Logwood, in chips, *one ounce* [avoirdupois]; Cinnamon, in coarse powder, *sixty grains;* Distilled Water *one pint* [Imperial measure]. Boil the Logwood in the Water for ten minutes in a covered vessel, adding the Cinnamon towards the end. Strain the decoction, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

We prefer the old U. S. formula, which ordered an ounce of the logwood to be boiled with two pints down to a pint, and doubt much whether the wood is exhausted by a boiling of ten or fifteen minutes. The cinnamon of the Br. formula is in general a very suitable addition; but there might be circumstances under which it would be better avoided; and in this case, as in others, any addition to the simple decoction might be left to the judgment of the prescriber.

This is an excellent astringent in diarrhœa; particularly in that form of it which succeeds the cholera infantum of this climate, or occurs as an original complaint in children during summer. The dose for an adult is two fluidounces, for a child about two years old, two or three fluidrachms, repeated several times a day. A little bruised cinnamon may often be added with advantage at the end of the boiling, as directed in the British process. W.

DECOCTUM HORDEI. *U. S., Br.* *Decoction of Barley.*

"Take of Barley *two troyounces;* Water *a sufficient quantity.* Having washed away the extraneous matters which adhere to the Barley, boil it with half a pint of Water for a short time, and throw away the resulting liquid. Then, having

poured on it four pints of boiling Water, boil down to two pints, and strain." *U. S.*

"Take of Pearl Barley *two ounces* [avoirdupois]; Distilled Water *one pint and a half* [Imperial measure]. Wash the Barley in cold water, and reject the washings; boil the washed barley with the Distilled Water for twenty minutes, in a covered vessel, and strain." *Br.*

Barley water, as this decoction is usually called, is much employed as a nutritive drink in febrile and inflammatory complaints, and, from the total absence of irritating properties, is peculiarly adapted to cases in which the gastric or intestinal mucous membrane is inflamed. As the stomach of those for whom it is directed is often exceedingly delicate, and apt to revolt against anything having the slightest unpleasantness of flavour, it is important that the decoction should be properly made; and, though the office of preparing it generally falls to nurses, yet the introduction of the process into the Pharmacopœia is not without advantage; as a formula is thus ever before the physician, by which he may give his directions, with the certainty, if obeyed, of having a good preparation. The use of the washing with cold water, and of the first short boiling, is completely to remove any mustiness, or other disagreeable flavour, which the barley may have acquired from exposure; and the British Pharmacopœia has probably erred in abandoning the second of these precautions. W.

DECOCTUM PAPAVERIS. *Br. Decoction of Poppies.*

"Take of Poppy Capsules, bruised, *two ounces* [avoirdupois]; Distilled Water *a pint and a half* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This decoction is used as an anodyne fomentation in painful tumours, and superficial cutaneous inflammation or excoriation. It is recommended not to reject the seeds, as their oil, suspended in the water by the mucilage of the capsules, adds to the emollient virtues of the preparation. W.

DECOCTUM PAREIRÆ. *Br. Decoction of Pareira.*

"Take of Pareira Root, sliced, *one ounce and a half* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for fifteen minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This is apt to remain turbid after straining, but, if allowed to stand, gradually deposits insoluble matter, and then filters perfectly clear. (*Pharm. Journ.*, xiv. 491.) The dose is from one to two fluidounces three or four times a day. W.

DECOCTUM QUERCÛS ALBÆ. *U.S. Decoction of White-oak Bark.* DECOCTUM QUERCUS. *Br. Decoction of Oak Bark.*

"Take of White-oak Bark, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the White-oak Bark in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Oak Bark [bark of Quercus pedunculata], bruised, *one ounce and a quarter* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

The U. S. Pharmacopœia of 1850 directed to boil an ounce of the bruised bark with a pint and a half of water down to a pint; and we have little doubt that the result was a more complete exhaustion of the bark than by the present process.

This decoction contains the tannin, bitter principle, and gallic acid of oak bark. It affords precipitates with the decoction of Peruvian bark and other substances containing vegetable alkaloids, with solution of gelatin, and with most metallic salts, particularly those of iron. Alkaline solutions diminish or destroy its astringency. Its uses have been already detailed. The dose is a wineglassful, frequently repeated. W.

DECOCTUM SARSÆ. *Br. Decoction of Sarsaparilla.*

"Take of Jamaica Sarsaparilla, cut transversely, *two ounces and a half* [avoirdupois]; Boiling Distilled Water *one pint and a half* [Imperial measure]. Digest the Sarsaparilla in the Water for an hour; boil for ten minutes in a covered vessel, cool, and strain, pouring distilled water, if required, over the contents of the strainer, or otherwise making the strained product measure a pint [Imp. meas.]." *Br.*

An idea was long entertained that the virtues of sarsaparilla resided in its fecula, the extraction of which was, therefore, the main object of the decoction. Hence the long boiling formerly ordered by the London and Edinburgh Colleges. But this opinion is now admitted to have been erroneous. The activity of the root is believed to depend upon one or more acrid principles, soluble to a certain extent in water cold or hot, and either volatilized, or rendered inert by chemical change, at the temperature of 212°. This fact appears to be demonstrated by the experiments of Pope,* Hancock,† Soubeiran,‡ Beral, and others. Soubeiran macerated one portion of bruised sarsaparilla in cold water for twenty-four hours; infused another portion in boiling water, and digested with a moderate heat for two hours; boiled a third portion bruised, and a fourth unbruised, in water for two hours; and in each instance used the same relative quantities. Testing these various preparations by the taste, he found the cold and hot infusions scarcely different in this respect; and both possessed of a stronger odour and more acrid taste than the decoctions, of which that prepared with the bruised root was the strongest. Beral has proved that *sarsaparillin*, which is believed to be the active principle of the drug, is volatile. From these facts the inference is obvious, that the best method of imparting the virtues of sarsaparilla to water is either by cold or hot infusion. Digestion for some hours in water maintained at a temperature of 180°, or somewhat less, in a covered vessel, has strong testimony in its favour. Percolation in a displacement apparatus, if properly conducted, is a convenient and no doubt efficient mode of exhausting the root, so far as water will effect that object. Decoction is the worst method; and the longer it is continued, the weaker will be the preparation. Accordingly, in the edition of the U. S. Pharmacopœia for 1850, an infusion of sarsaparilla was substituted for the simple decoction, though abandoned in the present edition as superfluous. It is probable that, as in the case of the Peruvian bark, a boiling of ten or fifteen minutes might be advantageously resorted to, when circumstances require the preparation to be made in less time than is requisite for infusion. In every instance the root should be thoroughly bruised, or reduced to a coarse powder, thus obviating the necessity for a long maceration, merely to overcome the cohesion of its fibres. These principles, so far as refers to the menstruum, have been recognised by the framers of the present British Pharmacopœia, in which long boiling has been abandoned. The unsplit root, however, is ordered, from the conviction, probably, that the internal amylaceous part is inert; but there can be no doubt that the drug yields its virtues more readily when well bruised or otherwise comminuted than in the natural state.

Precipitates are produced by various substances with this decoction; but it has not been ascertained how far such substances interfere with its activity. Those which merely throw down the fecula do not injure the preparation.

By this preparation it is possible to administer sarsaparilla in the form of decoction, without combination with other medicines, as in the Compound Decoction; and hence it may be considered as a desirable officinal.

The decoction of sarsaparilla may be administered in the dose of four or six fluidounces four times a day. W.

* Trans. of the Medico-chirurg. Society of London, vol. xii. p. 344.

† Trans. of the Medico-botan. Society of London. See also Journ. of the Philad. Col. of Pharm., vol. i. p. 295. The observations of Dr. Hancock are entitled to much credit, as he practised long in South America, in the neighbourhood of the best sarsaparilla regions

‡ Journ. de Pharmacie, tom. xvi. p. 38.

DECOCTUM SARSAPARILLÆ COMPOSITUM. *U.S.* Decoctum Sarsæ Compositum. *Br. Compound Decoction of Sarsaparilla.*

"Take of Sarsaparilla, sliced and bruised, *six troyounces;* Bark of Sassafras Root, sliced, Guaiacum Wood, rasped, Liquorice Root, bruised, each, *a troyounce;* Mezereon, sliced, *one hundred and eighty grains;* Water *a sufficient quantity.* Macerate with four pints of Water for twelve hours; then boil for a quarter of an hour, strain, and add sufficient Water, through the strainer, to make the decoction measure four pints." *U. S.*

"Take of Jamaica Sarsaparilla, cut transversely, *two ounces and a half;* Sassafras Root, in chips, Guaiac Wood turnings, Fresh Liquorice Root, bruised, each, *a quarter of an ounce;* Mezereon Bark *sixty grains;* Boiling Distilled Water *one pint and a half* [Imperial measure]. Digest the solid ingredients in the Water for an hour; then boil for ten minutes in a covered vessel; cool and strain, pouring distilled water, if required, over the contents of the strainer, or otherwise making the strained product measure a pint [Imp. meas.]." *Br.* The ounce employed in this process is the avoirdupois ounce.

This decoction is an imitation of the celebrated *Lisbon diet drink.* The sarsaparilla and mezereon are the active ingredients; the guaiacum wood imparting scarcely any of its virtues, and the sassafras and liquorice serving little other purpose than to communicate a pleasant flavour.

If prepared with good sarsaparilla, and with a due regard to the practical rules which may now be considered as established, the decoction may be used with great advantage as a gentle diaphoretic and alterative in secondary syphilis, either alone, or as an adjuvant to a mercurial course; also in certain scrofulous and other depraved conditions of the system, in chronic rheumatism, and in various obstinate cutaneous affections. The dose is from four to six fluidounces three or four times a day. The patient during its use should wear flannel next the skin, and avoid unnecessary exposure to changes of temperature.* W.

DECOCTUM SCOPARII. *Br. Decoction of Broom.*

"Take of Broom-tops, dried, *one ounce* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This decoction is used as an adjuvant to more powerful diuretics in dropsy. From half a pint to a pint may be taken during the day, in doses of from two to four fluidounces. W.

DECOCTUM SENEGÆ. *U.S. Decoction of Seneka.*

"Take of Seneka, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Seneka in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

In the British Pharmacopœia the decoction of seneka has been superseded by the infusion. (See *Infusum Senegæ.*)

* The *Decoction of Zittmann* (Decoctum Zittmanni) is a preparation of Sarsaparilla much used in Germany, for similar purposes with our compound decoction of sarsaparilla; and, as it has attracted some attention in this country as a remedy in obstinate ulcerative affections, we give the formula of the Prussian Pharmacopœia, which is generally followed in its preparation.—"Take of sarsaparilla *twelve ounces;* spring water *ninety pounds.* Digest for twenty-four hours; then introduce, enclosed in a small bag, *an ounce and a half* of sugar of alum (*saccharum aluminis* seu *saccharum aluminatum*, consisting of equal parts of *powdered alum* and *the whitest sugar*), *half an ounce* of calomel, and *a drachm* of cinnabar. Boil to thirty pounds, and near the end of the boiling add of aniseed, fennel-seed, each, *half an ounce*, senna *three ounces*, liquorice root *an ounce and a half.* Put aside the liquor under the name of THE STRONG DECOCTION. To the residue add *six ounces* of sarsaparilla and *ninety pounds* of water. Boil to thirty pounds, and near the end add lemon-peel, cinnamon, cardamom, liquorice, of each, *three drachms.* Strain and set aside the liquor under the name of THE WEAK DECOCTION." Mercury was detected by Wiggers in this decoction in very small proportion. It should not be prepared in metallic vessels lest the mercurial in solution should be decomposed. The decoction may be drunk freely

This is one of the decoctions in which experience has shown that long boiling impairs the activity of the medicine; and the substitution in our Pharmacopœia of a moderate boiling, for the former direction to boil down from a pint and a half to a pint, was certainly judicious.

It is customary to add to the seneka in decoction an equal weight of liquorice root, which serves to cover its taste, and in some measure to obtund its acrimony. The virtues and practical application of seneka have been already treated of. (See *Senega.*) The dose of the decoction is about *two fluidounces* three or four times a day, or a tablespoonful every two or three hours. W.

DECOCTUM TARAXACI. *Br. Decoction of Taraxacum.*

"Take of Dried Dandelion Root, sliced and bruised, *one ounce* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This decoction is most efficient when prepared, as in the present British Pharmacopœia, from the root alone. The dose is a wineglassful two or three times a day. (See *Taraxacum.*) W.

DECOCTUM ULMI. *Br. Decoction of Elm Bark.*

"Take of Elm Bark, cut in small pieces, *two and a half ounces* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint." *Br.*

For the uses of this preparation, see the article on Elm Bark in *Part* I. The dose is from two to four fluidounces. W.

DECOCTUM UVÆ URSI. *U. S. Decoction of Uva Ursi.*

"Take of Uva Ursi *a troyounce;* Water *a sufficient quantity.* Boil the Uva Ursi in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

The decoction of uva ursi has been superseded, in the British Pharmacopœia, by the infusion. (See *Infusum Uvæ Ursi.*)

The preparation contains the tannin, extractive, and gallic acid of the leaves. For an account of its uses, see *Uva Ursi.* The dose is from one to two fluidounces three or four times a day. W.

DIGITALIUM.

Digitalin.

DIGITALINUM. *Br. Digitalin.*

"Take of Digitalis Leaf, in coarse powder, *forty ounces* [avoirdupois]; Rectified Spirit, Distilled Water, Acetic Acid, Purified Animal Charcoal, Solution of Ammonia, Tannic Acid, Oxide of Lead in fine powder, Pure Ether, of each, *a sufficiency.* Digest the Digitalis with a gallon [Imperial measure] of the Spirit for twenty-four hours at a temperature of 120°; then put them into a percolator, and, when the tincture has ceased to drop, pour a gallon [Imp. meas.] of Spirit on the contents of the percolator, and allow it slowly to percolate through. Distil off the greater part of the Spirit from the tincture, and evaporate the remainder over a water-bath until the whole of the alcohol has been dissipated. Mix the residual extract with five [fluid]ounces of Distilled Water to which half an ounce [avoird.] of Acetic Acid has been previously added, and digest the solution thus formed with a quarter of an ounce of Purified Animal Charcoal; then filter, and dilute the filtrate with Distilled Water until it measures a pint [Imp. meas.]. Add Solution of Ammonia nearly to neutralisation, and afterwards add one hundred and sixty grains of Tannic Acid dissolved in three [fluid]ounces of Distilled Water. Wash the precipitate that will be formed with a little Distilled Water; mix it with a small quantity of the Spirit and a

quarter of an ounce of the Oxide of Lead, and rub them together in a mortar. Place the mixture in a flask, and add to it four [fluid]ounces of the Spirit; raise the temperature to 160°, and keep it at this heat for about an hour. Then add a quarter of an ounce of Purified Animal Charcoal; put it on a filter, and from the filtrate carefully drive off the Spirit by the heat of a water-bath. Lastly, wash the residue repeatedly with Pure Ether." *Br.*

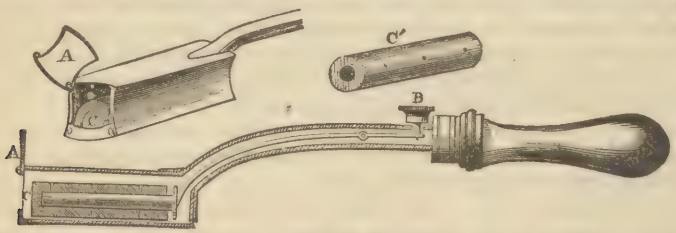
The above process is that of Homolle simplified by M. O. Henry, which has long occupied a place in this Dispensatory, and has been continued in the present edition, under the head of *Digitalis* in *Part* I. Everything has been there said which the subject seems to require. We do not think that the Council have been happy in their title of the preparation, made by affixing a Latin termination to the French. Digitalium is the proper Latin name for the active principle of digitalis, unless found to be alkaline, as it probably some time will be, when it should be called digitalia. The dose to begin with should not exceed the fiftieth or sixtieth of a grain. W.

EMPLASTRA.

Plasters.

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Most of them have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the U. S. Pharmacopœia. Those plasters which contain none of the compound of oil and litharge owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and oleaginous matter.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change colour and to become hard and brittle; and, as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be as much as possible excluded. The defect may usually be remedied by melting the plaster with a moderate heat, and adding a sufficient quantity of oil to give it the due consistence.



Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheep skin. A margin about a quarter or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper, so cut as to leave in the centre a vacant space of the required dimensions, and removing the paper when no longer needed. The same object may often be accomplished by employing two narrow rulers of sheet tin graduated in inches, and so shaped that each of them may form two sides of a rectangle. (See the figure, p. 936.) These may be applied in such a manner as to enclose within them any given rectangular space, and may be fixed by weights upon the leather while the plaster is spread.* For any other shape, as in the instance of plasters

* We are informed by a good practical pharmaceutist that this proposed plan of regulating the size and shape of plasters is not successful in practice; as, unless the tin is

for the breast, pieces of tin may be employed having a vacuity within, corresponding to the required outline. The spreading of the plaster is most conveniently accomplished by means of a peculiar iron instrument employed for the purpose; though a common spatula will answer.* This may be heated by means of a spirit lamp. Care must be taken that the instrument be not so hot as to discolour or decompose the plaster; and special care is requisite in the case of those plasters which contain a volatile ingredient. A sufficient portion of the plaster should first be melted by the heated instrument, and, having been received on a piece of coarse stiff paper, or in a shallow tin tray open on one side, should, when nearly cool, be transferred to the leather, and applied quickly and evenly over its surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. Before removing the paper from the edge of the plaster, if this has become so hard as to crack, the iron should be drawn over the line of junction. When linen or muslin is used, and the dimensions of the portion to be spread are large, as is often the case with adhesive plaster, the best plan is to pass the cloth "on which the plaster has been laid through a machine, formed of a spatula fixed by screws at a proper distance from a plate of polished steel." A machine for spreading plasters is described by M. Hérent in the *Journ. de Pharm.* (3e sér., ii. 403).† W.

kept in close contact with the leather or cloth by some steady and equable pressure, the plaster is apt to pass beneath the edge, and thus make an irregular outline; nor do the weights on the corners obviate the difficulty. (*Note to the thirteenth edition.*)

* The common plaster spatula is too well known to need description. In the *Am. Journ. of Pharm.* (xxv. 29) are figures of a plaster spatula, with an instrument employed for heating it, the invention of Mr. Stockton, of Brompton, England, which present certain advantages that render them worthy of notice. We introduce the figures here, with the following description, taken from the *Lond. Pharm. Journ.* for Nov. 1853. "The blade is a hollow

case into which the heater is inserted, having a door (A) at one end, and connected at the other, by a hollow tube, with the handle. The heater (C) is supported on a lever, which passes through the hollow tube, and terminates in a thumb-button (B). By depressing the button the heater is raised so as not to be in contact with the lower part of the spatula. On removing the thumb when more heat is required, the heater is depressed, and produces the desired effect. The heater, which consists of a hollow tube of thick copper, slides on a pin which forms the termination of the lever, and which regulates its position in the box. Some heaters are perforated, to admit of their being easily heated by means of gas. The chief advantage of the spatula consists in the facility with which the heat may be regulated by means of the lever and button, which latter is quite under the control of the thumb. The box containing the heater is of brass, and, not being inserted in the fire, may be more readily kept clean than the common spatula. When several plasters are required, the heater may be removed and another inserted with facility." To the *Am. Journ. of Pharm.* (xxvi. 15) the reader is referred for the figure of another spatula which may be found convenient. (*Note to the twelfth edition.*)

† Within a few years it has been customary with apothecaries to employ an apparatus, such as that figured on the next page, for spreading quantities of plasters. An oblong rectangular block of hard wood (*a e*) has its upper surface (*c*) gently convex. To this is attached by a movable joint (at *r*) a sheet iron frame (*b*), with an opening (*n*) of the dimensions of the plaster to be spread, and clasps (*d*) at the other end, by which this may be fixed to the block. Another portion of the apparatus is a wooden measure (*m*), by which the leather is cut out, and the margin marked. The leather thus prepared is laid on the convex surface of the block (*c*); the sheet iron frame is brought down on it evenly (as at *h i*); the plaster, previously melted, is poured on the leather in the centre, and, by means of an iron instrument (*g*) previously heated by a spirit lamp, is spread uniformly

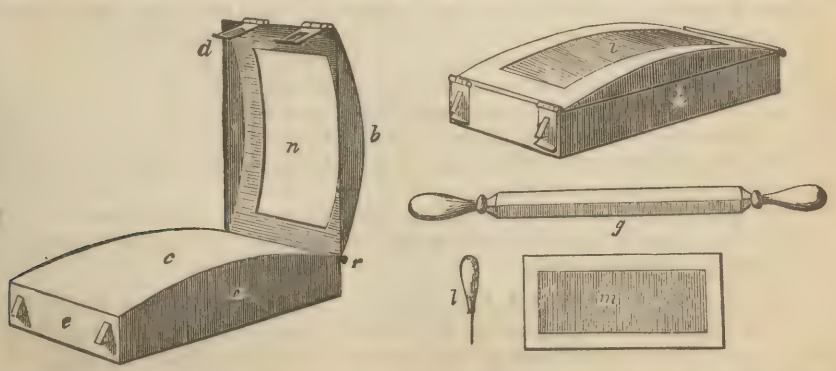
EMPLASTRUM AMMONIACI. *U.S. Plaster of Ammoniac.*

"Take of Ammoniac *five troyounces;* Diluted Acetic Acid *half a pint.* Dissolve the Ammoniac in the Diluted Acetic Acid, and strain; then evaporate the solution by means of a water-bath, stirring constantly until it acquires a proper consistence." *U. S.*

This plaster has been omitted in the British Pharmacopœia.

As ammoniac is not usually kept purified in our shops, the straining of the solution in the diluted acid is directed, as the most convenient method of separating impurities. Dr. Duncan remarked that the plaster, prepared in iron vessels, "acquires an unpleasant dark colour, from being impregnated with iron, whereas, when prepared in a glass or earthenware vessel, it has a yellowish-white colour, and more pleasant appearance." Care should also be used to avoid iron spatulas in its preparation, as the acetic acid acts on that metal, and discolours the plaster. The use of a moderate heat will facilitate the action of the diluted acid; and at best it is a thick creamy mass that is obtained, which requires the aid of the hand to strain it properly.

Medical Properties. The ammoniac plaster is stimulant, and is applied over scrofulous tumours and chronic swellings of the joints, to promote their resolution. It often produces a papular eruption, and sometimes occasions considerable inflammation of the skin. W.



EMPLASTRUM AMMONIACI CUM HYDRARGYRO. *U.S., Br. Plaster of Ammoniac with Mercury.*

"Take of Ammoniac *twelve troyounces;* Mercury *three troyounces;* Olive Oil *sixty grains;* Sublimed Sulphur *eight grains.* Heat the Oil, and gradually add the Sulphur, stirring constantly until they unite; then add the Mercury, and triturate until globules cease to be visible. Boil the Ammoniac with sufficient water to cover it until they are thoroughly mixed; then strain through a hair sieve, and evaporate, by means of a water-bath, until a small portion taken from the vessel hardens on cooling. Lastly, add the Ammoniac, while yet hot, gradually to the mixture of Oil, Sulphur, and Mercury, and thoroughly incorporate all the ingredients." *U. S.*

"Take of Ammoniacum *twelve ounces* [avoirdupois]; Mercury *three ounces* [avoird.]; Olive Oil *one fluidrachm;* Sublimed Sulphur *eight grains.* Heat the Oil, and add the Sulphur to it gradually, stirring till they unite. With this mixture triturate the Mercury until globules are no longer visible; and, lastly, add the Ammoniacum, previously liquefied, mixing the whole carefully." *Br.*

The only use of the sulphur is to aid in the extinguishment of the mercury;

over the surface, the thickness being regulated by the frame against which the iron is pressed. Any excess of plaster is thus pressed over upon the frame. The point of a sharp

instrument (*l*) is then drawn along the interior edge of the frame so as to separate the plaster from it, after which the clasps are unfastened and the plaster removed.

as the compound formed by it with the metal is probably inert. When ammoniac not previously prepared is used, as it is not fusible by heat, it must be brought to the proper consistence by softening it in a small quantity of hot water, straining, and evaporating.

Medical Properties and Uses. This plaster unites with the stimulant power of the ammoniac the specific properties of the mercury, which is sometimes absorbed in sufficient quantity to affect the gums. It is used as a discutient in enlargement of the glands, tumefaction of the joints, nodes, and other indolent swellings, especially when dependent on a venereal taint. It is also sometimes applied over the liver in chronic hepatitis. W.

EMPLASTRUM ANTIMONII. *U. S. Plaster of Antimony.*

"Take of Tartrate of Antimony and Potassa, in fine powder, *a troyounce;* Burgundy Pitch *four troyounces.* Melt the Pitch by means of a water-bath, and strain; then add the powder, and stir them well together until the mixture thickens on cooling." *U. S.*

This is a useful formula, as it will probably supersede the former irregular methods of preparing the antimonial plaster, of which the most primitive was to sprinkle the tartar emetic in powder upon the surface of adhesive plaster, somewhat softened with heat. It affords one of the most convenient methods of obtaining the local pustulating effects of tartar emetic. For its effects and uses, see *Antimonii et Potassæ Tartras*, page 1020. W.

EMPLASTRUM ARNICÆ. *U. S. Plaster of Arnica.*

"Take of Alcoholic Extract of Arnica *a troyounce and a half;* Resin Plaster *three troyounces.* Add the Extract to the Plaster, previously melted by means of a water-bath, and mix them." *U. S.*

These ingredients incorporate readily, and form a good plaster. The preparation was introduced into the Pharmacopœia, to enable the apothecary to meet the demand for a convenient preparation of arnica for external use. It is supposed to be useful in sprains and bruises, and sometimes probably acts beneficially by its stimulant properties in chronic rheumatism and other chronic external inflammations. (See *Arnica.*) W.

EMPLASTRUM ASSAFŒTIDÆ. *U. S. Plaster of Assafetida.*

"Take of Assafetida, Plaster of Lead, each, *twelve troyounces;* Galbanum, Yellow Wax, each, *six troyounces;* Alcohol *three pints.* Dissolve the Assafetida and Galbanum in the Alcohol by means of a water-bath, strain the liquid while hot, and evaporate to the consistence of honey; then add the Plaster and Wax previously melted together, stir the mixture well, and evaporate to the proper consistence." *U. S.*

This plaster has been omitted in the British Pharmacopœia.

The directions of the U. S. Pharmacopœia indicate the mode in which the gum-resins may be brought to the liquid state, before being incorporated with the other ingredients. Galbanum melts sufficiently by the aid of heat to admit of being strained; but this is not the case with assafetida, which must be prepared by dissolving it in a small quantity of hot water or alcohol, straining, and evaporating to the consistence of honey; and even galbanum may be most conveniently treated in the same way. Formerly these gum-resins were ordered merely to be melted and strained.

This plaster may be advantageously applied over the stomach or abdomen, in cases of hysteria attended with flatulence, and to the chest or between the shoulders in hooping-cough. W.

EMPLASTRUM BELLADONNÆ. *U. S., Br. Plaster of Belladonna.*

"Take of Alcoholic Extract of Belladonna *a troyounce;* Resin Plaster *two troyounces.* Add the Extract to the Plaster, previously melted by means of a water-bath, and mix them." *U. S.*

"Take of Extract of Belladonna, Resin Plaster, each, *three ounces* [avoirdupois]; Rectified Spirit *six fluidounces* [Imperial measure]. Rub the Ex-

tract and Spirit together in a mortar, and when the insoluble matter has subsided, decant the clear solution, remove the spirit by distillation or evaporation, and mix the alcoholic extract thus obtained with the Resin Plaster melted by the heat of a water-bath, continuing the heat until with constant stirring the plaster has acquired a suitable consistence." *Br.*

The most convenient method of forming this plaster is to rub the ingredients together in an earthenware mortar, placed in hot water, and then, having removed the mortar from the water-bath, to continue the trituration till the mixture cools. It was formerly prepared with the extract made from the inspissated juice of the leaves, and is so still in the British process; but, in the present edition of the U. S. Pharmacopœia, the alcoholic extract has been substituted with the effect of rendering the plaster easier to be spread and more adhesive. The preparation is a useful anodyne application in neuralgic and rheumatic pains, and in dysmenorrhœa. We have seen the constitutional effects of belladonna result from its external use. W.

EMPLASTRUM CALEFACIENS, *Br. Warm Plaster.*
See EMPLASTRUM PICIS CUM CANTHARIDE. *U. S.*

EMPLASTRUM CANTHARIDIS. *Br. Cantharides Plaster. Blistering Plaster.*
See CERATUM CANTHARIDIS. *U. S.*

EMPLASTRUM CERATI SAPONIS. *Br. Soap Cerate Plaster.*

"Take of Hard Soap, in powder, *ten ounces* [avoirdupois]; Yellow Wax *twelve and a half ounces* [avoird.]; Olive Oil *one pint* [Imperial measure]; Oxide of Lead *fifteen ounces* [avoird.]; Vinegar *one gallon* [Imp. meas.]. Boil the Vinegar and Oxide of Lead together, by the heat of a steam-bath, constantly stirring them until the Oxide has combined with the Acid; then add the Soap and boil again until most of the moisture is evaporated; finally, add the Wax and Oil melted together, and stir the whole continuously, maintaining the heat until by the evaporation of the remaining moisture the product has acquired the proper consistence for a plaster." *Br.*

This is the old *Ceratum Saponis Compositum* of the London College, the name of which has been changed in the British Pharmacopœia, because, the former class of Cerates having been abandoned, it was necessary to put the preparation into another class with a different title. It is not strictly a plaster, as this term is understood in American pharmacy; for heat is not required to spread it, being applied to the leather or cloth by means of a spatula, like our Cerates, to which it properly belongs. Indeed, it is essentially the same preparation as the U. S. *Ceratum Saponis*, consisting like that of soap plaster with wax and olive oil, though made differently, and containing some acetate of soda, as an incidental result of the process. In the British formula, subacetate of lead is first formed by the boiling of litharge or oxide of lead with vinegar; and the subacetate is then converted, by double decomposition with hard soap, into a compound of the oxide of lead and the fatty acids of the soap, and acetate of soda, which, with some glycerin formed in the process, remains as an ingredient of the lead plaster. The process is completed by incorporating this with the melted wax and oil, thus in fact converting the preparation into a cerate. The U. S. Ceratum Saponis was formerly prepared in the same way; but the process was superseded in the last revision of the Pharmacopœia by the neater one now officinal. For the uses of this preparation, see *Ceratum Saponis*, page 1082. W.

EMPLASTRUM FERRI. *U. S., Br.* EMPLASTRUM ROBORANS. *Plaster of Iron. Chalybeate Plaster. Strengthening Plaster.*

"Take of Subcarbonate of Iron *three troyounces;* Plaster of Lead *twenty-four troyounces;* Burgundy Pitch *six troyounces.* Add the Subcarbonate of Iron to the Plaster and Burgundy Pitch, previously melted together, and stir them constantly until the mixture thickens on cooling." *U. S.*

"Take of Hydrated Peroxide of Iron, in fine powder, *one ounce;* Burgundy Pitch *two ounces;* Lead Plaster *eight ounces.* Add the Peroxide of Iron to the Burgundy Pitch and Lead Plaster, previously melted together, and stir the mixture constantly till it stiffens on cooling." *Br.*

This preparation has enjoyed some popular celebrity, under the impression that it strengthens the parts to which it is applied; whence it has derived the name of strengthening plaster. It is used in those conditions of the loins, larger muscles, and joints, which, though usually ascribed to debility, are in fact most frequently dependent on rheumatic or other chronic inflammatory affection, and, if relieved by the plaster, are so in consequence of the gentle excitation produced by it in the vessels of the skin, or of the exclusion of the air. It may also, in some instances, give relief by affording mechanical support; but neither in this, nor in any other respect, can it be deemed very efficient. W.

EMPLASTRUM GALBANI. *Br. Galbanum Plaster.*

"Take of Galbanum, Ammoniacum, Yellow Wax, of each, *one ounce;* Lead Plaster *eight ounces.* Melt the Galbanum and Ammoniacum together, and strain. Then add them to the Lead Plaster and Wax, also previously melted together, and mix the whole thoroughly." *Br.*

The galbanum and ammoniac are best prepared by dissolving them in a small quantity of hot water or diluted alcohol, straining the solution, and evaporating it to the proper consistence for mixing with the other ingredients. W.

EMPLASTRUM GALBANI COMPOSITUM. *U.S. Compound Plaster of Galbanum.*

"Take of Galbanum *eight troyounces;* Turpentine *a troyounce;* Burgundy Pitch *three troyounces;* Plaster of Lead *thirty-six troyounces.* To the Galbanum and Turpentine, previously melted together and strained, add first the Burgundy Pitch, and afterwards the Plaster melted over a gentle fire, and mix the whole together." *U. S.*

Before being employed in this process, the galbanum should be purified, as it often contains foreign matters which must injure the plaster. It may be freed from these by melting it with a little water or diluted alcohol, straining, and evaporating to the due consistence.

This and the preceding plaster act as an excellent local stimulant in chronic scrofulous enlargements of the glands and joints. We have employed the compound plaster in obstinate cases of this kind, which, after having resisted general and local depletion, blistering and other measures, have yielded under its use. As a discutient it is also employed in the induration which sometimes remains after the discharge of abscesses. It is said to have been useful in rickets, applied over the whole lumbar region, and has been recommended in chronic gouty and rheumatic articular affections. It should not be used in the discussion of tumours in which any considerable inflammation exists. W.

EMPLASTRUM HYDRARGYRI. *U.S., Br. Mercurial Plaster.*

"Take of Mercury *six troyounces;* Olive Oil, Resin, each, *two troyounces;* Plaster of Lead *twelve troyounces.* Melt the Oil and Resin together, and, when they have become cool, rub the Mercury with them until globules of the metal cease to be visible. Then gradually add the Plaster, previously melted, and mix the whole together." *U. S.*

"Take of Mercury *three ounces;* Olive Oil *one fluidrachm;* Sublimed Sulphur *eight grains;* Lead Plaster *six ounces.* Heat the Oil and add the Sulphur to it gradually, stirring until they unite; with this mixture triturate the Mercury until globules are no longer visible, then add the Lead Plaster, previously liquefied, and mix the whole thoroughly." *Br.* The ounce employed in this process is the avoirdupois ounce.

The U. S. and former British processes may be considered as identical in their results. The sulphuretted oil which was employed in the process of the London College to facilitate the extinguishment of the mercury was abandoned

in the first British Pharmacopœia, as, just in proportion to the increased facility of the process, it lessened the efficacy of the resulting plaster; sulphuret of mercury being wholly inert. Nevertheless, the Pharmacopœia has in its late revision gone back to the old London formula. Mr. Thomas Blunt has found it almost impossible to divide the mercury sufficiently by trituration with oil and resin, and the resulting plaster was so crumbly that it could not be formed into rolls; but, by substituting a weight of Venice turpentine equal to that of the oil and resin combined, he found it to answer completely. An objection, however, to the turpentine is, that it might render the plaster too irritant for susceptible skins. (*Pharm. Journ. and Trans.*, July, 1864, p. 56.)

This plaster is employed to produce the local effects of mercury upon venereal buboes, nodes, and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. In these cases it sometimes acts as a powerful discutient. It is frequently also applied to the side in chronic hepatitis or splenitis. In peculiarly susceptible persons, it occasionally affects the gums.

From observations made in France by M. Serres and others, it appears that the mercurial plaster of the Codex (*Emplastrum de Vigo cum Mercurio*) has the power, when applied over the eruption of smallpox, before the end of the third day from its first appearance, to check its progress, and prevent suppuration and pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. It is also thought that the course of the disease is favourably modified when the mercurial impression is produced upon the system. That the local effect is not ascribable to the mere exclusion of the air is proved by the fact, that the use of lead plaster was not followed by the same results. It is probable that other mercurial preparations would answer the same purpose; and the common mercurial ointment has, in our own hands, proved effectual in rendering the eruption upon the face to a considerable extent abortive, in one bad case of smallpox. But as the most successful results were obtained with the plaster above mentioned, we give the formula of the French Codex for its preparation. The weights mentioned are those of the French metrical pound. (See *table in the Appendix.*)

Emplastrum de Vigo cum Mercurio. "Take of simple plaster [lead plaster] *two pounds eight ounces;* yellow wax *two ounces;* resin *two ounces;* ammoniac, bdellium, olibanum, and myrrh, each, *five drachms;* saffron *three drachms;* mercury *twelve ounces;* turpentine [common European] *two ounces;* liquid storax *six ounces;* oil of lavender *two drachms.* Powder the gum-resins and saffron, and rub the mercury with the storax and turpentine in an iron mortar until completely extinguished. Melt the plaster with the wax and resin, and add to the mixture the powders and volatile oil. When the plaster shall have been cooled, but while it is yet liquid, add the mercurial mixture, and incorporate the whole thoroughly." This should be spread upon leather or linen cloths, and applied so as effectually to cover the part to be protected. W.

EMPLASTRUM OPII. *U. S.*, *Br.* *Plaster of Opium.*

"Take of Extract of Opium *a troyounce;* Burgundy Pitch *three troyounces;* Plaster of Lead *twelve troyounces;* Water *a sufficient quantity.* Mix the Extract with three fluidounces of Water, and evaporate, by means of a water-bath, to a fluidounce and a half. Add this to the Burgundy Pitch and Plaster, melted together by means of a water-bath, and continue the heat for a short time, stirring constantly, that the moisture may be evaporated." *U. S.*

"Take of Opium, in fine powder, *one ounce;* Resin Plaster *nine ounces.* Melt the Resin Plaster by means of a water-bath; then add the Opium by degrees, and mix thoroughly." *Br.*

We decidedly prefer the extract of opium, as employed in the present U. S. process, to the opium itself of the British formula. It not only forms a better plaster, but, being soluble, is more likely to produce the anodyne effect desired, by being brought by the perspiration to the liquid state necessary for its absorption. The use of water in the former process is also an advantage, as it

enables the opium to be more thoroughly incorporated with the other ingredients; but care should be taken that the moisture be well evaporated.

The opium plaster is thought to relieve rheumatic and other pains in the parts to which it is applied. W.

EMPLASTRUM PICIS. *Br. Pitch Plaster.*

"Take of Burgundy Pitch *twenty-six ounces;* Common Frankincense [Terebinthina, U. S.] *thirteen ounces;* Resin, Yellow Wax, of each, *four ounces and a half;* Expressed Oil of Nutmeg *one ounce;* Olive Oil, Water, of each, *two fluidounces.* Add the Oils and the Water to the Frankincense, Burgundy Pitch, Resin, and Wax, previously melted together; then, constantly stirring, evaporate to a proper consistence." *Br.* The ounce used in this process is the avoirdupois ounce, and the fluidounce that of the Imperial measure.

This is a rubefacient plaster, applicable to catarrhal and other pectoral affections, chronic inflammation of the liver, and rheumatic pains in the joints and muscles. It often keeps up a serous discharge, which requires that it should be frequently renewed. The irritation which it sometimes excites is so great as to render its removal necessary. W.

EMPLASTRUM PICIS BURGUNDICÆ. *U. S. Plaster of Burgundy Pitch.*

"Take of Burgundy Pitch *seventy-two troyounces;* Yellow Wax *six troyounces.* Melt them together, strain, and stir constantly until they thicken on cooling." *U. S.*

In this formula, the object of the wax is simply to give a proper consistence to the Burgundy pitch, and to prevent it from breaking in cold weather. W.

EMPLASTRUM PICIS CANADENSIS. *U. S. Plaster of Canada Pitch. Hemlock Pitch Plaster.*

"Take of Canada Pitch *seventy-two troyounces;* Yellow Wax *six troyounces.* Melt them together, strain, and stir constantly until they thicken on cooling." *U. S.*

The yellow wax, in this preparation, answers the same purpose as in the Burgundy Pitch Plaster, and is even more necessary, in order to give additional consistence to the Canada Pitch, which, when pure, is somewhat too soft, at the temperature of the body, for convenient application. W.

EMPLASTRUM PICIS CUM CANTHARIDE. *U. S.* EMPLASTRUM CALEFACIENS. *Br. Plaster of Pitch with Cantharides. Warming Plaster.*

"Take of Burgundy Pitch *forty-eight troyounces;* Cerate of Cantharides *four troyounces.* Melt them together by means of a water-bath, and stir constantly until the mixture thickens on cooling." *U. S.*

"Take of Cantharides, in coarse powder, Expressed Oil of Nutmeg, Yellow Wax, Resin, of each, *four ounces* [avoirdupois]; Soap Plaster *three pounds and a quarter* [avoird.]; Resin Plaster *two pounds* [avoird.]; Boiling Water *one pint* [Imperial measure]. Infuse the Cantharides in the Boiling Water for six hours; squeeze strongly through calico, and evaporate the expressed liquid by a water-bath till reduced to one-third. Then add the other ingredients, and melt in a water-bath, stirring well until the whole is thoroughly mixed." *Br.*

This Plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication. As prepared by the former U. S. process, it occasionally blistered; and the proportion of cantharides has, therefore, been considerably diminished in the present formula; but, while such a reduction may render the plaster insufficiently active in most cases, it does not entirely obviate the objection; as the smallest proportion of flies would vesicate in certain persons, and even the Burgundy pitch alone sometimes produces the same effect. In whatever mode, therefore, this plaster may be prepared, it cannot always answer the expectations which may be entertained; and the only plan, when the skin of any individual has been found

to be very susceptible, is to accommodate the proportions to the particular circumstances of the case. Much, however, may be accomplished by care in the preparation of the plaster, towards obviating its tendency to blister. If the flies of the *Ceratum Cantharidis* have been coarsely pulverized, the larger particles, coming in contact with the skin, will exert upon the particular part to which they may be applied their full vesicatory effect, while, if reduced to a very fine powder, they would be more thoroughly enveloped in the other ingredients, and thus have their strength much diluted. Hence the cerate, when used as an ingredient of the warming plaster, should contain the cantharides as minutely divided as possible; and, if that usually kept is not in the proper state, a portion should be prepared for this particular purpose. A good plan, we presume, would be to keep the cerate used in this preparation, for a considerable time, at the temperature of 212°, and then strain it so as to separate the flies. (See *Ceratum Cantharidis.*) The mode frequently pursued of preparing the warming plaster by simply sprinkling a very small proportion of powdered flies upon the surface of Burgundy pitch is altogether objectionable. The U. S. process is that of the old Dublin Pharmacopœia. We strongly approve of that portion of the British process which uses an inspissated infusion of the flies, as an equable distribution of these is thus ensured.

It has been objected to the U. S. plaster that it is apt to be too soft in hot weather. Mr. G. C. Close, ascribing this inconvenience to the proportion of lard in the cerate employed, proposes to obviate it by substituting Burgundy pitch plaster for Burgundy pitch, and powdered cantharides for the cerate, and offers a formula in compliance with this suggestion. (See *Am. Journ. of Pharm.*, Jan. 1867, p. 20; from *Proceed. of Am. Pharm. Association*, 1866.)

The warming plaster is employed in chronic rheumatism, and various chronic internal diseases attended with inflammation or an inflammatory tendency; such as catarrh, asthma, pertussis, phthisis, hepatitis, and the sequelæ of pleurisy and pneumonia. W.

EMPLASTRUM PLUMBI. *U. S.*, *Br.* Emplastrum Lithargyri. *Br.* 1864. *Plaster of Lead. Litharge Plaster.*

"Take of Oxide of Lead [Litharge], in fine powder, *thirty troyounces;* Olive Oil *fifty-six troyounces;* Water *a sufficient quantity.* Sift the Oxide of Lead into the Oil, contained in a suitable vessel, of a capacity equal to twice the bulk of the ingredients. Then add half a pint of boiling Water, and boil the whole together until a plaster is formed; adding from time to time, during the process, a little boiling Water, as that first added is consumed." *U. S.*

"Take of Oxide of Lead, in fine powder, *four pounds;* Olive Oil *one gallon;* Water *three pints and a half.* Boil all the ingredients together gently by the heat of a steam-bath, and keep them simmering for four or five hours, stirring constantly, until the product acquires a proper consistence for a plaster, and adding more water during the process if necessary." *Br.* The weights used in this process are the avoirdupois, and the measures the Imperial.

The importance of this plaster, as the basis of most of the others, requires a somewhat detailed account of the principles and manner of its preparation.

It was formerly thought that the oil and oxide of lead entered into direct union, and that the presence of water was necessary only to regulate the temperature, and prevent the materials from being decomposed by heat. The discovery, however, was afterwards made, that this liquid was essential to the process; and that the oil and oxide alone, though maintained at a temperature of 220°, would not combine; while the addition of water, under these circumstances, would produce their immediate union. It was now supposed that the oil was capable of combining only with the hydrated oxide of lead, and that the use of the water was to bring the oxide into that state; and, in support of this opinion, the fact was advanced that the hydrated oxide of lead and oil would form a plaster, when heated together without any free water. But, since the general reception of Chevreul's views in relation to oils, and their combinations with alkalies and other metallic oxides, the former opinions have been abandoned;

and it is now admitted that the preparation of the lead plaster affords a genuine example of saponification, as explained by that chemist. A reaction takes place between the oil and water, resulting in the development of a sweetish substance called *glycerin*, and of two acid bodies, the *oleic* and *margaric acids*, to which, when animal fat is employed instead of olive oil, a third is added, namely the *stearic*. The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact an oleo-margarate of lead. The glycerin remains dissolved in the water, or mechanically mixed with the plaster. That such is the correct view of the nature of this compound is evinced by the fact, that, if the oxide of lead be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water. According to a more recent chemical view, the fixed oils are compounds of the oily acids mentioned and *oxide of glyceryl*. When boiled with the oxide of lead and water, the oily acids combine with the metallic oxide to form the plaster, and the oxide of glyceril takes an equivalent of water and becomes glycerin. *Glyceryl* is a hypothetical compound of carbon and hydrogen (C_6H_7), which unites with five equivalents of oxygen to form oxide of glyceryl ($C_6H_7O_5$), also a hypothetical substance, and additionally with an equivalent of water to form glycerin ($C_6H_7O_5+HO$).

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to *M. Henry*, of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of lead plaster to the German. From more recent experiments of Soubeiran, it appears that massicot or even minium may be substituted for litharge, and a plaster of good consistence be obtained; but that a much longer time is required for completing the process than when the officinal formula is followed. When minium is used, the necessity for its partial deoxidation renders a longer continuance of the process necessary than with massicot. According to M. Davallon, Professor in the School of Medicine and Pharmacy at Lyons, it is important that the olive oil employed should be pure; for when adulterated, as it frequently is in commerce, it yields an imperfect product. Mr. N. S. Thomas prepared a good plaster by substituting lard for olive oil, in the proportion of eight pounds of lard to five of litharge (*Am. Journ. of Pharm.*, xix. 175); and we are told that it is a common practice, in this country, to make lead plaster with a mixture of lard oil and olive oil.

Lead plaster has also been prepared by double decomposition between soap and acetate or subacetate of lead; but the results have not been so advantageous as to lead to the general adoption of this process. For particular information on the subject, the reader is referred to the *American Journal of Pharmacy* (ix. 127), and to the *Journal de Pharmacie* (xxiii. 163 and 322).*

Preparation. The vessel in which the lead plaster is prepared should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would therefore delay the process. While the water exerts an important chemical agency in the changes which oc-

* M. de Mussy, physician of the hospital *de la Pitié*, having witnessed inconveniences from lead plaster in consequence of the absorption of the lead, substituted for it a plaster with a basis of oxide of zinc, which he has found to answer very well in practice. It cannot be made by direct combination of the oxide; and it is necessary to have recourse to the method of double decomposition. Solutions of white olive oil soap and of sulphate of zinc being mixed, a copious precipitate takes place of oleo-margarate of zinc, which, after being washed and dried, may be combined with resins, oil, and wax, to give it the necessary consistence. This preparation, however, is not likely to supersede the officinal. (*Journ. de Pharm.*, xxvii. 100.)—*Note to the eleventh edition.*

cur, it is also useful by preventing too high a temperature, which would decompose the oil, and cause the reduction of the oxide. The waste must, therefore, be supplied by fresh additions as directed in the process; and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator. During the continuance of the boiling, the material should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side, so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably, in consequence partly of the vaporization of the water, partly of the escape of carbonic acid gas, which is liberated by the oily acids from some carbonate of lead usually contained in the litharge. The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the colour and consistence of the mass. The colour of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick, when a portion of the plaster, taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red points, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and, having been well kneaded under water, in order to separate the viscid solution of glycerin contained in the interior, should be formed into cylindrical rolls, and wrapped in paper. Such at least has been the course of proceeding usually recommended. But M. Davallon maintains that the presence of glycerin in the plaster is useful by keeping it in a plastic state, and that washing and kneading are injurious, the former by removing the glycerin, the latter by introducing particles of air and moisture into the mass, which is thus rendered more disposed to rancidity. (*Am. Journ. of Pharm.*, xv. 274; from *Journ. de Chim. Méd.*) By employing steam heat in the preparation of this plaster, the risk of burning it is avoided. For a good arrangement for this purpose, see *Mohr and Redwood's Pharmacy*, edited by Prof. Procter, p. 420.

Mr. C. Lewis Diehl has found it almost impossible, in following the U. S. directions, to obtain a plaster wholly free from uncombined litharge. He obviates the difficulty by first rubbing the sifted litharge with about half its weight of oil, then stirring the mixture with the remainder of the oil, in a tinned copper kettle, adding the water, and heating to 212° until a uniform plaster is formed. This occupies from one to two days. The boiling of the plaster, which, as it requires the use of dry heat, is apt to cause the product to be burned, is not essential. (*Am. Journ. of Pharm.*, Sept. 1867, p. 385.)

Medical Properties and Uses. This plaster, which has long been known under the name of *diachylon*, is used as an application to excoriated surfaces, and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead colic resulted from its long-continued application to a large ulcer of the leg. (*Am. Journ. of Med. Sci.*, xxiii. 246.) Its chief use is in the preparation of other plasters. While in its yet incomplete state, it is used in the preparation of glycerin.*

* *Logan's Plaster.* Take of Litharge, Carbonate of Lead, each, *a pound;* Castile Soap *twelve ounces;* Butter (fresh) *four ounces;* Olive Oil *two and a half pints;* Mastic, in powder, *two drachms.* It is to be understood that the pound and ounce are of the avoirdupois weight. Having mixed the Soap, Oil, and Butter, add the Litharge, and boil the mixture gently, constantly stirring, for an hour and a half, or until it shall assume a pale-brown colour; then increase the heat somewhat, and continue to boil, until a portion of the liquid, dropped on a smooth board, is found not to adhere to it on cooling; then remove it from the fire, and mix the mastic with it. Logan's plaster has long been in popular use in Philadelphia, and is considerably employed by regular practitioners, as a protective and discutient application.

Off. Prep. Emplastrum Assafœtida, *U. S.;* Emp. Ferri; Emp. Galbani, *Br.;* Emp. Galbani Compositum, *U. S.;* Emp. Hydrargyri; Emp. Opii, *U. S.;* Emp Resinæ; Emp. Saponis. W.

EMPLASTRUM PLUMBI IODIDI. *Br.* *Iodide of Lead Plaster.*

"Take of Iodide of Lead *one ounce;* Soap Plaster, Resin Plaster, each, *four ounces.* Add the Iodide of Lead, in fine powder, to the Plasters previously melted, and mix them intimately." *Br.*

This is a local discutient plaster, which may also be used with other means to affect the system. (See *Plumbi Iodidum,* Part II.) W.

EMPLASTRUM RESINÆ. *U. S., Br.* *Resin Plaster. Adhesive Plaster.*

"Take of Resin, in fine powder, *six troyounces;* Plaster of Lead *thirty-six troyounces.* To the Plaster, melted over a gentle fire, add the Resin, and mix them." *U. S.*

"Take of Resin *four ounces;* Lead Plaster *two pounds;* Hard Soap *two ounces.* To the Lead Plaster, previously melted with a gentle heat, add the Resin and Soap, first liquefied, and stir them until they are thoroughly mixed." *Br.* The weights here referred to are the avoirdupois.

This preparation differs from the lead plaster in being more adhesive and somewhat more stimulating. It is the common adhesive plaster of the shops, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other, and a firm support is given to the granulations. As prepared by the Dublin College it contained soap, which gave it greater pliability, and rendered it less liable to crack in cold weather, without impairing its adhesiveness; and the process of that College has been adopted in the British Pharmacopœia. It is usually spread upon muslin; and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept in the shops ready spread; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. When the skin is very delicate, it occasionally excites some irritation, and, under these circumstances, a plaster may be substituted containing a smaller proportion of resin. That originally employed by Baynton contained only six drachms of resin to the pound of lead plaster. To obviate the same evil, M. Herpin recommends the addition of tannate of lead, the proportion of which, when adhesiveness is required in the plaster, should not exceed one-twentieth, but, under other circumstances, may be increased to one-twelfth (*Bullet. de Thérap.,* xlviii. 155.)

In order to render the plaster more adhesive, and less brittle in cold weather, it is customary with many apothecaries to employ a considerable proportion of Burgundy pitch or turpentine in its preparation; but these additions are objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended.*

Plaster of Carbonate of Lead. This was originally introduced into our Pharmacopœia as a substitute for *Mahy's plaster,* at one time much employed in some parts of the United States; but was omitted in the edition of 1840. It is a good application to surfaces inflamed or excoriated by friction; and may be resorted to with advantage in those troublesome cases of cutaneous irritation, and even ulceration, which are apt to occur upon the back and hips during long-continued confinement to one position. We give the process as contained in the Pharmacopœia of 1830. "Take of Carbonate of Lead *a pound;* Olive Oil *two pints;* Yellow Wax *four ounces;* Lead plaster *a pound and a half;* Florentine Orris, in powder, *nine ounces.* Boil together the Oil and Carbonate of Lead, adding a little water, and constantly stirring, till they are thoroughly incorporated; then add the Wax and Plaster, and, when these are melted, sprinkle in the Orris, and mix the whole together." By this process, a good plaster may be prepared, rather too soft at first, but soon acquiring the proper consistence.

* An adhesive plaster, exempt from oxide of lead, is prepared by Pettenkofer. It consists of calcareous soap incorporated with turpentine and suet, and may be prepared in

Off. Prep. Emplastrum Arnicæ, *U. S.;* Emplastrum Belladonnæ; Emplast. Calefaciens, *Br.;* Emplast. Opii, *Br.;* Emplast. Plumbi Iodidi, *Br.* W.

EMPLASTRUM SAPONIS. *U. S., Br. Soap Plaster.*

"Take of Soap, sliced, *four troyounces;* Plaster of Lead *thirty-six troyounces;* Water *a sufficient quantity.* Rub the Soap with Water until brought to a semi-liquid state; then mix it with the Plaster previously melted, and boil to the proper consistence." *U. S.*

"Take of Hard Soap *six ounces;* Lead Plaster *two pounds and a quarter;* Resin *one ounce.* To the Lead Plaster, melted by a gentle heat, add the Soap and the Resin, first liquefied; then, constantly stirring, evaporate to a proper consistence." *Br.* The avoirdupois weights are used in this process.

The present U. S. formula is an improvement upon that of a former edition of the Pharmacopœia. The proportion of soap in the old process was so large as to render the plaster friable. It has been diminished from six to four ounces. Besides, by the present mode of proceeding, it is more thoroughly incorporated with the plaster. The same end of greater plasticity is accomplished, in some degree, in the British process by the resin. In preparing the U. S. plaster, Mr. C. Lewis Diehl has found some difficulty in rubbing the soap up perfectly and rapidly with the water, and has, therefore, adopted the plan of first rubbing the soap with its weight of water, then straining the mixture through coarse muslin, and lastly reducing the residue with a proportionate quantity of water, before stirring the whole into the melted plaster. (*Am. Journ. of Pharm.*, Sept. 1867, p. 386.)

Soap plaster is considered discutient, and is sometimes used as an application to tumours.

ENEMATA.

Clysters.

These can scarcely be considered proper objects for officinal direction; but, having been introduced into the former British Pharmacopœias, and retained in the present, the plan of this work requires that they should be noticed. They are substances in the liquid form, intended to be thrown up the rectum, with the view either of evacuating the bowels, of producing the peculiar impression of a remedy upon the lower portion of the alimentary canal and neighbouring organs, or of acting on the system generally through the medium of the surface to which they are applied. They are usually employed to assist the action of remedies taken by the mouth, or to supply their place when the stomach rejects them, or is insensible to their impression. Sometimes they are preferably used when the seat of the disorder is in the rectum or its vicinity. As a general rule, three times as much of any remedy is required to produce a given impression by enema, as when taken into the stomach; but this rule should be acted on with caution, as the relative susceptibilities of the stomach and rectum are not the same in all individuals; and, with regard to all very active remedies, the best plan is to administer less than the stated proportion. Attention should also be paid to the fact, that, by the frequent use of a medicine, the susceptibility of the stomach may be in some measure exhausted, without a proportionate diminution of that of the rectum.

When the object is to evacuate the bowels, the quantity of liquid administered should be considerable; for an adult, from ten fluidounces to a pint; for a child

the following manner. A solution of soap is decomposed by a solution of chloride of calcium. The precipitate, having been expressed and dried, is powdered with half its weight of turpentine dried by heat; and the mixture is melted, along with an eighth part of suet, in boiling water. The mixture is boiled until the mass melts into a homogeneous fluid, when it is worked by the hand, in the ordinary manner, in cold water. Should portions of the calcareous soap not melt, they should be separated by straining through flannel. (*Journ. de Pharm.*, 3e sér., x. 358; from *Repertorium für die Pharm.*, xiii. 40.)

of eight or ten years, half that quantity; for an infant within the year, from one to three fluidounces. Much larger quantities of mild liquids may sometimes be given with safety and advantage; as the bowels will occasionally feel the stimulus of distension, when insensible to irritating impressions.

When the design is to produce the peculiar impression of the remedy upon the neighbouring parts, or on the system, it is usually desirable that the enema should be retained, and the vehicle should therefore be bland, and as small in quantity as is compatible with convenient administration. A solution of starch, flaxseed tea, or other mucilaginous fluid should be selected, and the quantity should seldom exceed two or three fluidounces. In every case, the patient should be instructed to resist any immediate disposition to discharge the injected fluid; and his efforts to retain it should be assisted, if necessary, by pressure with a warm folded towel upon the fundament. The best instrument for administering enemata is an accurate metallic syringe. W.

ENEMA ALOES. *Br.* *Enema of Aloes.*

"Take of Aloes *forty grains;* Carbonate of Potash *fifteen grains;* Mucilage of Starch *ten fluidounces.* Mix, and rub together." *Br.*

This is intended as a formula for the use of aloes in cases of ascarides in the rectum, and of amenorrhœa attended with constipation. W.

ENEMA ASSAFŒTIDÆ. *Br.* *Enema of Assafetida.* ENEMA FŒTIDUM. *Ed., Dub.* *Fetid Enema.*

"Take of Assafetida *thirty grains;* Distilled Water *four fluidounces.* Rub the Assafetida in a mortar with the Water added gradually, so as to form an emulsion." *Br.*

This is carminative and antispasmodic as well as laxative. In the former Br. Pharmacopœia it was directed to be made by mixing the tincture and Distilled Water; and, in commenting on it, we stated that we should prefer a preparation consisting of the gum-resin rubbed up with water; as the alcohol of the tincture might in some instances prove injurious. In the present formula this plan has been adopted. The whole quantity directed may be administered at once. W.

ENEMA MAGNESIÆ SULPHATIS. *Br.* *Enema of Sulphate of Magnesia.* ENEMA CATHARTICUM. *Ed., Dub.* *Cathartic Clyster.*

"Take of Sulphate of Magnesia *one ounce* [avoirdupois]; Olive Oil *one fluidounce;* Mucilage of Starch *fifteen fluidounces* Dissolve the Sulphate of Magnesia in the Mucilage, add the Oil, and mix." *Br.*

The laxative enema, most commonly employed in this country, consists of a tablespoonful of common salt, two tablespoonfuls of lard or olive oil, the same quantity of molasses, and a pint of warm water. It has the advantage of consisting of materials which are always at hand in families, and is in all respects equal to the officinal preparation. W.

ENEMA OPII. *Br.* *Enema of Opium.* ENEMA OPII vel ANODYNUM. *Ed.* *Anodyne Enema.*

"Take of Tincture of Opium *half a fluidrachm;* Mucilage of Starch *two fluidounces.* Mix." *Br.*

This formula is unobjectionable. It must have happened to every one in the habit of prescribing opium in this way, to have seen a much greater effect produced by a certain amount of laudanum injected into the rectum than by one-third of the quantity swallowed. The fluidrachm contains at least one hundred drops of laudanum of the ordinary size, and not less than one hundred and twenty as they are often formed. From twenty to twenty-five drops are usually considered as a medium dose by the mouth; so that sixty drops, equivalent to about thirty minims, are abundantly sufficient by enema. As the object is that the enema should remain in the rectum, the smaller the quantity of the vehicle the better; and a mucilaginous fluid is preferable to water, as it involves the tincture, and prevents the irritation of the alcohol before the opium begins to

take effect. The ordinary anodyne enema, employed in this country, consists of about sixty drops of laudanum and one or two fluidounces of flaxseed tea or solution of starch, conforming precisely with the present British formula.

This is an admirable remedy in obstinate vomiting, strangury from blisters, painful affections of the kidneys, bladder, and uterus, and in the tenesmus of dysentery. It may also frequently be employed to produce the effects of opium upon the system, when circumstances prevent the administration of that medicine by the mouth. W.

ENEMA TABACI. *Br. Enema of Tobacco.*

"Take of Leaf Tobacco *twenty grains;* Boiling Water *eight fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The whole quantity is to be given at once. The dose is somewhat less than that usually employed in this country. (See *Infusum Tabaci.*) W.

ENEMA TEREBINTHINÆ. *Br. Enema of Turpentine.*

"Take of Oil of Turpentine *one fluidounce;* Mucilage of Starch *fifteen fluidounces.* Mix." *Br.*

For the dose of this preparation, see *Oleum Terebinthinæ.* W.

EXTRACTA.

Extracts.

Extracts, as the term is employed in the Pharmacopœias, are solid substances, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing the vegetable to the action of a solvent, or by expressing its juice in the recent state. A distinction was formerly made between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, the former being called *Extracta*, the latter *Succi Spissati;* but the distinction has been generally abandoned. There is no such essential difference between these two sets of preparations as to require that they should be separately classed; and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union. We shall consider them under the same head, taking care, however, to detail distinctly whatever is peculiar in the mode of preparing each.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant, with as little of the inert matter as possible; though sometimes it may be desirable to separate two active ingredients from each other, when their effects upon the system are materially different; and this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, colouring matter, salts, and the peculiar principles of plants; to which, when a spirituous solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil; gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in the Materia Medica. There is one, however, which, from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive*, or, as it is sometimes called, *extractive matter.*

It has long been observed that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep-brown colour, and becoming itself insoluble. This substance, originally called

saponaceous matter by Scheele, afterwards received the more expressive name of *extractive*, derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted, by some chemists, who consider the phenomena supposed to result from its presence, as depending upon the mutual reaction of other principles; and, in relation to Peruvian bark, it appears to have been proved that the insoluble matter which forms during its decoction in water is a compound of starch and tannin. A similar compound must also be formed in other cases when these two principles coexist; but they are not always present in the same vegetable, nor can all the changes which have been attributed to extractive be accounted for by their union, even when they are present; so that, till further light is shed on the subject, it is best to admit the existence of a distinct substance, which, though not the same in all plants, possesses sufficient identity of character to be entitled, like sugar, resin, &c., to a distinctive name. The most interesting property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. If chlorine be passed through an infusion or decoction, a similar precipitate is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has, therefore, been called, in its altered condition, oxidized extractive; but De Saussure ascertained that, though oxygen is absorbed during the process, an equal measure of carbonic acid gas is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is, therefore, obviously incorrect; and Berzelius proposed to substitute for it that of *apotheme*, synonymous with deposit. According to Berzelius, apotheme is not completely insoluble in water, but imparts a slight colour to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it; thus acquiring properties somewhat different according to the source from which it is obtained. In this way, also, even when the extractive of a plant is itself medicinally inert, its conversion into apotheme may be injurious by causing a precipitation of a portion of the active principle; and, in practical pharmaceutic operations, this change should always, if possible, be avoided. With these preliminary views, we shall proceed to the consideration of the practical rules necessary to be observed in the preparation of extracts. We shall treat of the subject under the several heads of, 1. the extraction of the soluble principles from the plant; 2. the method of conducting the evaporation; 3. the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them; and 4. the general directions of the Pharmacopœias in relation to them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract; 1. by expression alone; 2. by the agency of a solvent, with or without expression.

1. *By Expression.* This method is applicable to recent vegetables. All plants cannot be usefully treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable portion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects for this treatment. The plants should be operated upon, if possible, immediately after collection. Mr. Battley, of London, recommended that, if not entirely fresh, they should be re-

vived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvas bag, and the liquid parts expressed. Mr. Brande states that light pressure only should be employed; as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. (*Manual of Pharmacy.*) The juice thus obtained is opaque and usually green, in consequence of the presence of green wax or chlorophyll, and of a portion of the undissolved vegetable fibre in minute division. By heating the juice to about 160°, the albumen contained in it coagulates, and, involving the chlorophyll and vegetable fibre, forms a greenish precipitate. If the liquid is now filtered, it becomes limpid and nearly colourless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle; in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of syrup. Ether added to the expressed juices of plants enables them to be kept long without injurious change. M. Lepage, of Gisors, France, has kept the juice of belladonna in this way more than 10 years, and found it, at the end of that time, to yield an extract, identical in physical, chemical, and physiological properties with that obtained from the fresh juice. If this fact is found to be of general applicability, it will be of considerable importance, as enabling the pharmaceutist to supply himself, at pleasure, with extracts to be relied on, without reference to the season. (*Journ. de Pharm.*, Mai, 1863, p. 361.)

2. *By Solution.* The active principles of dried vegetables can be extracted only by means of a liquid solvent. The menstruum usually employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action, if necessary, by a higher degree of heat than the latter. Pump water is often unfit for the purpose, in consequence of the quantity of its saline matter, which, in some instances, may exert an unfavourable influence on the active principle, and must always be left in the extract. Rain, river, or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble, or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils and the active principle of sarsaparilla; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The watery solution requires to be soon evaporated, as this fluid rather promotes than counteracts chemical changes; while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable; and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively, than of both united. Extracts obtained by the agency of water are called *watery* or *aqueous extracts;* those by means of alcohol, undiluted or diluted, *alcoholic* or *spirituous extracts.* Sometimes the term *hydro-alcoholic* is applied to extracts obtained by the joint agency of alcohol and water.

The method of preparing the solution is not a matter of indifference. The vegetable should be thoroughly bruised, or reduced to a coarse powder, so as to

allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved and inactive portion. When water is employed, it has been customary to boil the medicine for a considerable time, and, if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions, till the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the decomposition of many vegetable principles, or at least so modifies them as to render them inert; and the extracts prepared by decoction are usually less efficient than those made with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat employed. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot infusion; in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter, and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is often preferable to the other modes, as starch, which is inert, is thus left behind ; but in many instances the preparation would spoil before the extraction would be completed. By *digestion*, though the solvent power of water is moderately increased, the advantage is often more than counterbalanced by the increased disposition to spontaneous decomposition. *Hot infusion*, therefore, is to be preferred where the vegetable does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without adding to its virtues. A convenient mode of performing this process, is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel with its mouth loosely stopped, then to pour on the boiling water, and, having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated till the water comes away without any obvious impregnation. It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long-continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both when decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it, as the latter thus escapes unnecessary exposure to heat.

Sometimes the filtering of a turbid infusion or decoction, before evaporation, causes the resulting extract to keep better, by removing substances which, besides undergoing decomposition themselves, may act as a ferment, and thus occasion the decomposition of the active matter of the extract.

When alcohol is employed as a menstruum, the vegetable should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration; as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels. When alcohol and water are both used, it is best, as a general rule, to exhaust the vegetable with each separately, as the two menstrua require different modes of treatment. In whichever of these modes the extraction is effected, it requires the assistance of occasional agitation; and, when the vegetable matter is very porous, and absorbs a large quantity of the solvent, expression must be resorted to.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo

Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and still stronger with alcohol to which strong acetic acid has been added. (*Journ. de Pharm*., 3e sér., i. 239.) This acid is used in the preparation of the acetic extract of colchicum.

Ether also is now used to a considerable extent in the preparation of certain extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the preparation of extracts from those substances, the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation or displacement, and the ether is then either allowed to escape by spontaneous evaporation, or is distilled off at a very moderate heat. The oleoresinous extracts thus obtained are usually of a thick fluid or semi-fluid consistence. For more precise information as to the mode of preparing them, the reader is referred to a paper by Prof. Procter, in the *Am. Journ. of Pharm.* (xxi. 114). Several of them are now ranked among the officinal preparations, in the U. S. Pharmacopœia, under the title of *Oleoresins*.

The process of percolation or displacement has within a few years been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages: 1. that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion; 2. that it effects the extraction much more quickly than can be done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and 3. that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing the injurious effects of the subsequent evaporation. While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed; for, though an inexpert or careless operator may incur loss by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskilfully prepared upon this plan. In the U. S. Pharmacopœia, all the extracts to which the process is applicable are prepared by percolation, and, with a very few exceptions, without previous maceration or digestion, which, as a general rule, is useless if not injurious. In the British Pharmacopœia, the process is applied, as it were, hesitatingly to a portion of the extracts, and withheld in others to which it seems equally appropriate; and, as if there was an unwillingness to trust this exotic method entirely, previous maceration for a greater or less length of time, never less than twelve, and more generally for twenty-four hours, is with a single exception universally adopted, whenever percolation is employed. In this respect British pharmacy is, we think, behind that of the United States. For an account of the mode of operating in the process of displacement, and of the instruments used, the reader is referred to pages 931 and 942.

Repercolation. In consequence of the existing high price of alcohol, and of the liquids prepared from it, as ether and chloroform, it is important to adopt some plan by which, while the ends aimed at are attained, the consumption of the menstruum used in percolation may be diminished. This object has been accomplished, to a considerable extent, by Dr. Ed. R. Squibb, of Brooklyn, N. Y., by a modification of the process of percolation to which he has given the name at the head of the present paragraph. As defined by Dr. Squibb, repercolation consists in the successive application of the same percolating menstruum to fresh portions of the substance to be percolated. The result is that the same menstruum, acting repeatedly on unexhausted portions of the medicine, becomes concentrated to the greatest possible extent; so that much of the menstruum is saved, while the amount of the subsequent evaporation is diminished, which is itself an object of great importance in the preparation of extracts. It is obvious that repercolation is not applicable to the preparation of infusions, decoctions, tinctures, &c., in which the object in general is less a high

degree of concentration than precision in the strength of the preparation, and consequently in the dose. It is to the extracts that the process is peculiarly adapted. One of its disadvantages is that the substance treated is less completely exhausted than when the proceeding is inverted, and fresh portions of menstruum are made to act on the same material until the latter is deprived of all its soluble matter. But the loss in this way is trifling, compared with the gain where a high-priced menstruum, as alcohol at the present time, is employed. In deciding when to adopt it, the operator will of course be influenced by the relative value of the drug and the menstruum, and decide in its favour only when the former is not so great as to overbalance the saving from the reduced quantity of the latter. In carrying repercolation into effect, in order to secure the most favourable results, certain methods of proceeding are advisable in various steps of the process, differing with the character of the substance to be acted on; and this can be determined only by a careful study, confirmed by repeated experiment. Dr. Squibb has applied it especially to the preparation of an extract of cinchona; and, by presenting in a note below an abstract of his plan of proceeding in this case, and the accompanying explanations, we can more forcibly impress on the mind of the pharmaceutical student the lessons applicable to the case than by abstract rules.*

* *Dr. Squibb's Process for Extract of Cinchona by Repercolation.* Take of Cinchona, in very fine powder, *forty-eight troyounces*, Alcohol *ten pints*, Water *a sufficiency*. Divide the Cinchona into three equal parts. Mix one part thoroughly with two pints of the Alcohol; allow the mixture to stand in a covered vessel for half an hour, and then transfer it to a ten-inch glass funnel for percolation; return the first two or three fluidounces that pass to the funnel; and pour in first five pints of the Alcohol, in portions of a pint each, waiting after each addition till the liquid has disappeared; and afterwards 20 fluidounces of Water. Continue the percolation till 6·5 pints have passed; dividing the percolate as it appears into portions, the first of two pints, and the remainder of a pint each, except the last, which is to be half a pint.

Mix the second part of the Cinchona with the first two pints of the percolate obtained, and proceed as with the first part, using the successive portions of percolate in the place of alcohol, until the last portion disappears. Then pour into the funnel a pint of the Alcohol, and when this has disappeared 20 fluidounces of Water. Continue the percolation till 7·5 pints have passed; separating the percolate into portions as before.

Mix the third part of the Cinchona with the first two portions of the percolate of the last operation, and proceed as with the second part, except that the remaining two pints of the Alcohol are to be poured into the funnel after the percolate and before the Water, and that the percolation is to continue till 9·5 pints of percolate are obtained, or till water appears in the percolate.

Recover the alcohol from the percolate by distillation for future use, and prepare the extract in the form directed.

The following explanatory observations by Dr. Squibb in relation to the foregoing process are important. The cinchona for percolation should be in the finest powder possible, and perfectly dry. The exhaustion is less economically effected with smaller quantities than 16 troyounces, used in each operation of the process; and a 10 or 10·5 inch funnel is of a convenient size. The mixture of the powder and alcohol, which should be made in a vessel of a capacity not less than half a gallon, may be effected by means of a wooden spatula, and should be free from lumps. After the magma has been put into the funnel, from 4 to 6 ounces of percolate may drain from it without the addition of menstruum; but this is not desirable, as the magma becomes impacted, and is less easily penetrated by the menstruum. The first two or three fluidounces that pass, being weak and sometimes turbid, are returned into the funnel, and the menstruum is to be immediately added, to prevent shrinking and impaction. The surface of the mass in the funnel, in the first part, should always be kept covered, when the alcohol is added; and, when the percolate is used in successive portions, one portion should be allowed to sink into the magma before another is applied; because these portions are successively weaker, and consequently better adapted to the more exhausted magma; but the surface should not remain long uncovered between the additions, as shrinking might take place and the percolation cease. Should it, however, have remained so, as when unwatched in the night, the whole surface should be gently pressed down in order to close the cracks; and this may be done without removing the paper from the surface. The percolate should throughout be perfectly transparent, and should pass at the average rate of a pint in 12 hours; though more rapid with the first portion, and slower with the third. The first part of each percolation is slower; and the rapidity increases with the exhaustion. To prevent loss of alcohol by evaporation, in consequence of the slowness of the percolation, the

Some prefer the mode of expression to that of displacement. This also is applicable both to watery and alcoholic menstrua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances; and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of a common screw press, or other convenient instrument. Another portion of the menstruum may then be added, and pressure again applied; and, if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantages over that of displacement, that it yields solutions of more uniform concentration, that it does not require the materials to be so carefully powdered, or otherwise so skilfully managed in order to ensure favourable results, and finally that it occupies less time.

2. *Mode of conducting the Evaporation.*

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact, that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapour. The operator should, therefore, observe two rules: 1. to conduct the evaporation at as low a temperature as is consistent with other objects; 2. to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. According to Berzelius, the injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat,

point of the funnel should pass well into the flask, and the funnel should be kept closely covered by India-rubber cloth, or oiled cloth or silk, and a plate.

Two accidents may occur here, either of which may spoil a process or even group of processes. If in emptying the funnel and preparing for a new percolation, the blanket or cork be left wet or even very damp, the new percolate will pass turbid from the beginning, and will often stop entirely. If, moreover, the tube of the funnel fit closely, as it should do, in the neck of the receiver, and its orifice do not project into the wider portion of the flask below, the interstice between the end of the funnel and neck of the flask is liable to be closed by the dropping liquid, so as to prevent the escape of air, and thus cause the percolate to pass upward through the interstice, and escape over the top of the receiver; and when this course is established, not a drop appears to fall into the flask.

After the last pint of the alcohol has been added, and disappeared beneath the surface, the water is poured into the funnel to displace the last portion of the spirituous menstruum, and is known to have sufficiently accomplished its object when it begins itself to appear in the percolate, as indicated by the turbidness produced by it in the tincture; and the process should be closely watched, so as to be suspended at this moment.

The percolate is very bitter, and deeply coloured; the tint varying with the variety of the bark; being of a deep, port-wine colour with the red, and nearly as dark as brown sherry with the yellow. If loss by evaporation be avoided, full 6·5 pints of alcoholic percolate may be obtained from the 7 pints of alcohol first employed; and a similar proportion from the other two parts, making altogether 9·5 pints. In obtaining this product from 10 pints of alcohol, about half a pint from the last percolation will contain some water, but not sufficient materially to interfere with the result.

The first part of the percolate is very dense, the last almost syrupy; and, were the process to be carried to the fourth percolation, it would become quite syrupy, so as to interfere with the passage of the liquid in any further repetition of the process; and a natural limitation of repercolation is thus afforded. The first pint of percolate is usually obtained in about 10 hours; the first from the second percolation in about 16 hours; that from the third in 24 hours; and the last pint of each, with little variation, in 8 or 10 hours.

The alcohol recovered by distillation is ready for use with other portions of cinchona; and the loss in the process varies from 20 to 30 per cent., according to the efficiency of the distillatory apparatus, and the care and skill employed. The alcohol used in percolation with the red bark retains a brown tint, that with the yellow is nearly or quite colourless. (*Proceedings of the Am. Pharm. Association*, A.D. 1867, p. 393; see also Pharmacy of the Cinchonas, *Am Journ. of Pharm.*, 1867, pp. 289, 398, and 513.)—***Note to the thirteenth edition.***

even allowing for the longer exposure in the latter case; and, therefore, a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe that decoctions generally let fall upon cooling a portion of insoluble matter; and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble tannate of starch formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a general rule, is to allow it to remain.

The method of evaporation usually resorted to in the case of aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted the better, provided the liquid is to be brought to the boiling point; for the temperature cannot exceed this, and the length of exposure is diminished. But, even where this method is employed, it should not be continued till the completion of the evaporation; for, when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire before it has attained the consistence of thick syrup, and completing the evaporation, either by means of a water-bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions and evaporate each separately; for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. (*Mohr.*) But the mode of evaporation by boiling is always more or less objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by decoction.

Evaporation by means of the water-bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but, as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and the temperature being nearly the same, when the water-bath is kept boiling, there is greater risk of injurious action from the air. The liquid should be stirred during the process. The use of the vapour-bath, as suggested by M. Henry, is perhaps preferable; as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, is less than 212°. We take the following description of the apparatus, employed at the Central Pharmacy of Paris, from M. Chevallier's highly useful Manual. It consists of a covered boiler, containing water, the vapour of which is conducted through a pipe into evaporating vessels, communicating with each other by means of metallic tubes. These vessels have the form of an ordinary copper basin, over the top of which is soldered a shallow tin capsule, intended to contain the liquor to be evaporated. The vapour from the boiler circulates through these vessels, and the water into which it condenses is allowed to escape through a stop-cock attached to the bottom of each vessel. From the last one of the series a tube passes into a vessel of water, so as to afford a slight pressure against the escape of any excess of vapour. The liquid to be evaporated is first distributed in two or three capsules, but, when considerably concentrated, is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid, if there are four vessels, is in that nearest the boiler about 198° F., in the fourth or most remote, about 135°. An incidental advantage of this apparatus is, that it affords a large supply of distilled water.

As the heat capable of being applied by a boiling water-bath to the evaporating liquid does not exceed 200° F., while that by steam can, by a moderate pressure, be increased to the boiling point or beyond it, the evaporation by the latter agency may be much more rapid than by the former, according to Mr. Redwood, twice as rapid, when the pressure is from ten to twenty pounds to

the square inch; so that there is a temptation to raise the heat to a degree seriously injurious to the product. Evaporation, therefore, by steam heat always requires caution, while the water-bath is much less liable to be abused. In this respect, the latter method has the advantage.

A good plan of evaporation, though slow, is to place the liquid in a broad, shallow vessel, exposed in a stove or drying room to a temperature of about 100°, or a little higher, taking care that the air have free access in order to facilitate the evaporation. This mode is particularly applicable to those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while those prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smith's bellows, over the surface of the liquid; and, in reference to substances which are injured by heat and not by atmospheric air, the plan will be found useful.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for evaporation in vacuo, invented by Mr. Barry, and described in the *Lond. Journ. of Science and Arts* (vol. viii. p. 360), is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapour more rapidly, and at a comparatively low temperature. The method of Barry consists in distilling the liquid into a large receiver, from which the air has been expelled by steam, and in which the vapour is condensed by cold water applied to the surface of the receiver, so as to maintain a partial vacuum. Mr. Redwood has modified this process by keeping an air-pump in action during the evaporation, thus removing not only the air, but the vapour as fast as it forms, and maintaining a more complete vacuum than can be done by the condensation of the vapour alone. (*Journ. de Pharm.*, 3e sér., i. 231.) Another method is to place the liquid under an exhausted receiver, together with some concentrated sulphuric acid or chloride of calcium, which, by its affinity for water, promotes the evaporation of the liquid. But, from the expense and trouble of these modes of evaporation, they are not calculated for general use. Dr. Christison recommends as probably the most perfect and convenient method, especially with watery infusions and decoctions, to evaporate the fluid in a vacuum to the consistence of syrup, and then to complete the process in shallow vessels, exposed to a current of air without heat.*

A convenient plan of excluding the air, though it does not at the same time meet the object of reducing the requisite degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo*. Care, however, must be taken that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water-bath.

* M. Grandval has described an apparatus for evaporation in vacuo, for the preparation of extracts, in the *Journ. de Pharm.* (xv. 82). In the same journal (xxiii. 1), MM. Soubeiran and Gobley have described and figured an apparatus, founded upon that of M. Grandval, but modified so as to be adapted to operations on a small scale, and to be within the reach of apothecaries who may desire to prepare their own extracts. Messrs. Tilden & Co., of New York, employ a vacuum apparatus analogous to that used in refining sugar. The vacuum is obtained and continued by the constant action of a powerful steam-driven pump. Their apparatus includes two evaporating pans; one large, having a capacity of several hundred gallons, used to concentrate the solutions for extracts to a syrupy consistence; the other, holding about fifty gallons, in which the evaporation is finished. The latter is furnished with an opening of such size as to permit the operator to remove the residual extract. The temperature during the evaporation is from 120° to 140° F., and is derived from steam pipes, placed within the boiler in the large evaporating pan, and a steam jacket beneath the smaller one. Very fine extracts are prepared in this way. (*Note to the ninth and tenth editions.*)

We are told that the vacuum pan is now much more used by pharmaceutical chemists than formerly. (*Note to the thirteenth edition.*)

In the concentration of alcoholic solutions, distillation should always be performed; as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water-bath should be employed, to obviate any possible risk of injury from the fire. When the decoction or infusion, and tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together, while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is, that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat, therefore, should be applied to the bottom, and not to the sides of the vessel.

3. *Condition and Preservation of Extracts.*

Extracts are prepared of two different degrees of consistence; soft so that they may be readily made into pills, and hard that they may be pulverized. In astringent extracts, the evaporation should be carried to dryness. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophyll, harden by time, in consequence of the escape of their moisture; and it not unfrequently happens that small crystals of saline matter are formed in their substance. Most extracts, especially those containing azotized principles, are capable, when left to themselves, of producing nitrates. Mr. John Attfield, of London, has made a chemical examination of the crystals found in numerous extracts, and ascertained that, in a large number, they consisted of chloride of potassium, and, in a comparatively few, of the nitrate of potassa.* The air, moreover, exercises an unfavourable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt, or any other very soluble salt of difficult decomposition, the greater part of it will be precipitated, in consequence of the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water.

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather, or a piece of bladder. (*Duncan.*) The dry extracts, being less liable to be affected by atmospheric oxygen, do not require so much care. The application of alcohol to the surface has a tendency to prevent mouldiness. A method of protecting extracts from the action of the air, frequently resorted to, is to cover them closely with oiled bladder; but this, though better than to leave them uncovered, is not entirely effectual. Should the extract become too moist, it may be dried by means of a water-bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner, and incorporating with it a little distilled water. (*Chevallier.*)

Some extracts when powdered have a tendency to cohere again. According to Geiseler, this may be obviated by the addition of sugar of milk or powdered

* Thus, chloride of potassium was detected in the extracts of belladonna, hemlock, sarsaparilla (compound), colchicum seeds, stramonium seeds, and aconite; nitrate of potassa in extracts of belladonna, hyoscyamus, and lettuce; and sulphate of soda in extract of stramonium seeds. (*Pharm. Journ.*, March, 1862, p. 448.)

liquorice-root; two or three parts of the former, and one part of the latter to one of the extract being sufficient for the purpose. (*Pharm. Cent. Blatt*, A. D. 1850, p. 238.) Mohr recommends the following plan of drying and preserving extracts. Take equal parts of powdered liquorice-root and of the extract, rub them well together in a mortar, put the resulting paste into an earthen vessel with a flat bottom, place this in another of iron, a little deeper, containing chloride of calcium thoroughly dried by heat insufficient to melt it; then enclose the whole with a cover fitted to the iron vessel, and allow them to stand for a day or more. When the mixture is quite dry, powder it, and add so much of the powdered root as to make the weight double that of the original extract. (*Ibid.*, p. 719.)

The incorporation of a little glycerin with extracts by adding it to the materials in the course of their preparation has been of late highly recommended, and by some carried into effect. By its unchangeable liquid character it keeps the extract soft, so as to be readily made into pills, and exercises also a favourable influence through its chemical properties; protecting in some degree against the oxidation of certain principles which render them insoluble, and dissolving apotheme already formed, as well as other principles that may not be soluble in the menstruum employed, as resin when water is used as the solvent. Mr. T. S. Wiegand considers glycerin as the best excipient for extracts given in the form of liquid mixture, or applied externally; equal parts being used in the former case, and a double proportion of glycerin in the latter. (*Am. Journ. of Pharm.*, March, 1863, p. 117.)

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; and a good rule is to prepare them once a year.*

4. *General Officinal Directions.*

"In preparing the Extracts, unless otherwise directed, evaporate as quickly as possible, in a broad, shallow vessel, by means of a water-bath, until they have acquired the consistence proper for forming pills; and, towards the end of the process, stir them constantly with a spatula. Sprinkle upon the softer Extracts a small quantity of Alcohol." *U. S.*

EXTRACTUM ACONITI. *Br. Extract of Aconite.*

"Take of the fresh Leaves and Flowering Tops of Aconite *one hundred and twelve pounds* [avoirdupois]. Bruise in a stone mortar, and press out the juice; heat it gradually to 130°, and separate the green colouring matter by a calico filter. Heat the strained liquor to 200° to coagulate the albumen, and again filter. Evaporate the filtrate by a water-bath to the consistence of a thin syrup; then add to it the green colouring matter previously separated, and, stirring the whole together assiduously, continue the evaporation at a temperature not exceeding 140°, until the extract is of a suitable consistence for forming pills." *Br.*

The extract from the fresh leaves of aconite has been abandoned in the U. S. Pharmacopœia, probably because the plant is not generally cultivated in this country. It will be perceived that, in the British process, not the leaves only,

* M. Lepage, of Gisors, gives the following method of testing the quality of the narcotic extracts, and determining whether they contain any of the alkaloids to which they owe their efficiency. Take a gramme (15·3 grs.) of the extract, dissolve it in twice its weight of distilled water, introduce the solution into a test-tube, and add from 25 to 30 centigrammes (4 or 5 grs.) of powdered bicarbonate of potassa. When effervescence has ceased, add to the mixture 5 or 6 times its bulk of pure ether, cork the tube, and shake briskly three times in 2 or 3 minutes. Then let the mixture rest; and, when the ether has become transparent, decant, and allow it to evaporate spontaneously. Dissolve the residue in 6 or 8 grammes (ʒiss to ʒij) of water, acidulated with a drop or two of muriatic acid. If the extract be good, the solution will be rendered very turbid by a few drops of a solution of the double iodide of mercury and potassium, and will give a flocculent precipitate with solution of tannic acid. (*Journ. de Pharm.*, Mai, 1863, p. 362.) This test is applicable to the extracts of aconite, belladonna, hyoscyamus, and conium. (*Note to the twelfth edition.*)

but the flowering tops also are used, as experience has shown that these are at least equally efficient. The process consists essentially in the evaporation of the expressed juice; and the product, therefore, ranks with inspissated juices.

In relation to the preparation of this extract, as well as of all others derived from the expressed juices of narcotic plants, the following summary of the plan pursued by Mr. Battley, an experienced apothecary of London, may be of service. Having passed the expressed juice through a fine hair sieve, he places it immediately upon the fire. Before it boils, a quantity of green matter rises to the surface, which in some plants is very abundant. This is removed by a perforated tin dish, and preserved. It ceases to appear soon after the liquid begins to boil. The boiling is continued till rather more than half the fluid has been evaporated, when the decoction is poured into a conical pan and allowed to cool. An abundant dark-green precipitate forms, from which the supernatant liquid is poured off; and this, having been reduced one-half by a second boiling, is again allowed to stand. The precipitate which now falls is less green than the first. The remaining fluid is once more placed over the fire, and allowed to boil till it assumes the consistence of syrup, when it is removed. The matter at first collected by skimming, together with that precipitated, is now incorporated with it, and the whole placed in a metallic pan, and by means of a water-bath evaporated to the consistence of an extract. In the latter part of the process, care is necessary to prevent the extract from hardening on the sides of the vessel, as it thus loses its fine green colour, and becomes proportionably feeble.

The superiority of this plan over a continuous boiling is, that the portions of active matter which are deposited at different stages of the process are subjected for a shorter time to heat than if allowed to remain in the liquor, and are consequently less deteriorated. The matter which coagulates before the fluid boils is chiefly albumen, embracing portions of chlorophyll and of the undissolved vegetable fibre. It might probably be thrown away without diminishing the virtues of the extract; but as chlorophyll, though itself inactive, has often associated with it a portion of the active principle, it is the most economical plan to incorporate it with the other matters, and, besides, its presence in the mass is said to render it easier to be worked into pills. Mr. Brande states that one cwt. of fresh aconite yields about five pounds of extract. According to Geiger, one pound yields an ounce and a half.

In the new process of the British Pharmacopœia, it will be perceived that a discrimination is made between the chlorophyll and albumen; the former, which coagulates at 130°, being at first separated in order to prevent the continuous action of heat upon it, and afterwards added to the extract; the latter, coagulating at 200°, is separated and rejected. The rejection of the albumen is altogether advisable, as it is not only inert, but renders the extract more liable to decomposition. The chlorophyll is retained for the reasons stated in the preceding paragraph; and also to give a greenish colour to the extract, which has come to be associated in general opinion with its goodness of quality.

When properly prepared, this extract has a greenish-brown colour, with a disagreeable narcotic odour, and the acrid taste of the plant. It may be given in the dose of one or two grains, night and morning, to be gradually increased till the system is affected. Twenty grains or more have been given in the course of a day. W.

EXTRACTUM ACONITI ALCOHOLICUM. *U. S.* *Alcoholic Extract of Aconite.*

"Take of Aconite Leaf, recently dried and in fine powder, *twelve troyounces*, Alcohol *a pint*; Diluted Alcohol *a sufficient quantity*. Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted

Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup, and add the three fluidounces of tincture first obtained. Lastly, continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

The exhaustion of the aconite in this process is indicated by the absence of its peculiar taste in the liquid which passes.

By the former U. S. process the alcohol in the evaporation was recovered by distillation and saved. In the present, this is impossible at the low temperature at which the evaporation is directed, unless by the aid of a vacuum apparatus; but, at the present high price of alcohol, it would be advisable for every apothecary, who prepares these alcoholic extracts, to be provided with such an instrument. The attempt to save the alcohol by ordinary distillation would imply an elevation of the heat above that officinally ordered, and thus endanger the decomposition of the active principle of the aconite; and views of economy should never be allowed to interfere with the efficiency of medicines.

If made from recently dried leaves, which have not yet been impaired by time, this is a good preparation of aconite; and it is believed to be more powerful, and to keep better, than the inspissated juice. According to Prof. Schroff, of Vienna, it has four times the strength of that preparation. The dose is half a grain or a grain, to be gradually increased if necessary.

An alcoholic extract prepared from the root is stronger, and may be given in the dose of one-sixth or one-quarter of a grain three times a day, to be gradually increased until its effects are experienced.* W.

EXTRACTUM ALOES BARBADENSIS. *Br. Extract of Barbadoes Aloes.*

"Take of Barbadoes Aloes, in small fragments, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure]. Add the Aloes to the Water, and stir well until they are thoroughly mixed. Set aside for twelve hours; then pour off the clear liquor, strain the remainder, and evaporate the mixed liquors by a water-bath or a current of warm air to dryness." *Br.*

EXTRACTUM ALOES SOCOTRINÆ. *Br. Extract of Socotrine Aloes.*

This is prepared precisely as the Barbadoes Aloes.

The object of these processes is to separate from Aloes the resinoid matter, the *apotheme* of Berzelius, which is supposed to irritate the bowels, without possessing purgative properties; but the truth appears to be, that, when deprived of a small proportion of adhering extractive, this matter is quite inert. It cannot, therefore, injuriously affect the virtues of the medicine; and, as it exists in comparatively small proportion, and during the process a part of the extractive becomes insoluble, the preparation may be considered as at best unnecessary. The dose of the purified aloes is from two to ten grains.†

Off. Prep. Decoctum Aloës Compositum, *Br.;* Extractum Colocynthidis Compositum, *Br.* W.

* *Plaster of Aconite.* It is often desirable to employ aconite externally in the form of a plaster, and for this purpose the alcoholic extract of the root may be advantageously resorted to. Professor Procter prepares such a plaster by the following process. Mix four ounces of the coarsely powdered root with six fluidounces of alcohol (sp. gr. 0·835), macerate for 24 hours, then submit the mixture to percolation with alcohol, so as to obtain a pint of tincture. From this distil off three-fourths of the alcohol, and evaporate the residue by a water-bath to a syrupy consistence. While it is still hot, add three ounces and a half of adhesive plaster, previously melted, and stir the mixture constantly till it cools. About four ounces of plaster are thus obtained. (*Am. Journ. of Pharm.*, xxv. 202.) —*Note to the tenth edition.*

† *Glycerate of Aloes. Glycerole of Aloes.* Under the latter name, M. Chausit brought to the notice of the profession a preparation consisting of an alcoholic extract of aloes dissolved in glycerin. Mr. Haselden prepared this in the following method. Macerating half an ounce of aloes in four fluidounces of alcohol until dissolved, he filtered the tincture through bibulous paper, evaporated it to the consistence of molasses, and, while it was

EXTRACTUM ANTHEMIDIS. *Br.* *Extract of Chamomile.*

"Take of Chamomile Flowers *one pound* [avoirdupois]; Oil of Chamomile *fifteen minims;* Distilled Water *one gallon* [Imperial measure]. Boil the Chamomile with the Water until the volume is reduced to one-half, then strain, press, and filter. Evaporate the liquor by a water-bath until the extract is of a suitable consistence for forming pills, adding the Oil of Chamomile at the end of the process." *Br.*

According to Mr. Brande, one cwt. of dried chamomile flowers affords upon an average 48 pounds of extract.

This extract has a deep-brown colour, with the bitter taste and aroma of chamomile. It much better represents the chamomile than the old Edinburgh extract, which, being obtained by decoction and inspissation, contained none of the volatile oil of the plant. In the present British process, not only is care taken to avoid boiling, but also to supply any possible loss of oil during the cautious evaporation, by the addition of a small portion near the close of the process. The extract may be given for the same purposes as the flowers, but is most used as a vehicle for other tonics in the pilular form. The dose is from ten to twenty grains. An extract may be prepared, having the peculiar flavour as well as bitterness of chamomile, by macerating the flowers in water, and evaporating the infusion in vacuo. W.

EXTRACTUM ARNICÆ ALCOHOLICUM. *U.S.* *Alcoholic Extract of Arnica.*

"Take of Arnica, in moderately coarse powder, *twenty-four troyounces*, Alcohol *four pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and moisten the powder with a pint of the mixture; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the mixture. Continue the percolation with Diluted Alcohol until six pints of tincture have passed. Lastly, evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

This extract very well represents the virtues of arnica, and is a convenient form for its administration. According to Prof. Procter, it amounts, in the soft state, to 33 per cent. of the flowers. The dose is from five to ten grains. But the chief employment of the extract is in the preparation of the plaster. (See *Emplastrum Arnicæ.*)

Off. Prep. Emplastrum Arnicæ, *U. S.* W.

EXTRACTUM BELLADONNÆ. *U.S., Br.* *Extract of Belladonna.*

"Take of Belladonna Leaf, fresh, *twelve troyounces.* Bruise the Leaf in a stone mortar, sprinkling on it a little water, and express the juice; then, having heated this to the boiling point, strain, and evaporate to the proper consistence." *U. S.*

The British Pharmacopœia takes the "fresh leaves and young branches of Belladonna," and prepares the Extract from them in the same manner precisely as Extract of Aconite. (See *Extractum Aconiti.*)

The U. S. Pharmacopœia directs this extract to be prepared from the leaves

till warm, added enough glycerin to make four fluidounces. Finding that the aloes was wholly dissolved, with the exception of a little impurity, he concluded that the spirit might very well be dispensed with, and the aloes used directly in the process. Accordingly, he proposes to substitute the following method. Mix well in a mortar half an ounce of Socotrine aloes, in fine powder, and four fluidounces of glycerin; transfer the mixture to a bottle, and agitate occasionally for several days; if the aloes be not now dissolved, heat for fifteen minutes by a water-bath, and strain through linen to separate impurities. The resulting liquid is of a bright mahogany colour, and of the consistence of glycerin. The preparation has been recommended as an external remedy in lichen agrius and the excoriations of eczema, applied by means of a camel's-hair brush. (*Pharm. Journ.*, Dec. 1859, p. 322.) It is unfortunate, we think, that the French name of glycerole has been employed to express solutions in glycerin, as this termination has been adopted for certain proximate principles. It appears to us that the term *glycerate* would be unexceptionable; as it is sufficiently expressive, and no confusion could result. For the mode of preparing *a fluid extract of aloes* with the aid of glycerin, by Prof. Procter, see *Proceed. of Am. Pharm. Assoc.*, 1863, p. 240. (*Note to the twelfth edition.*)

of the plant, the British from the leaves and young branches. The latter direction was probably based on experiments by Mr. Squire, of London, who found that an extract prepared from the soft herbaceous parts of the plant generally, including leaves, flowers, and young stalks, not only has a better consistence, and is less apt to become mouldy by keeping, than that made from the leaves exclusively, but is more effectual in the same quantity. (*Pharm. Journ.*, Dec. 1861, p. 300.) There is little doubt of the accuracy of these results, and it is to be hoped that, in a future edition of our officinal standard, should they be confirmed by further observation, the same measure may be adopted. It is probable that these remarks are as applicable to other extracts prepared from fresh leaves as to that of belladonna, at least in relation to perennial plants.

From the experiments of MM. Solon and Soubeiran, it appears that, in relation to this extract, the insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, are nearly if not quite inert; so that advantage results from clarifying the juice by these means before evaporating it. So far as the albumen is concerned, there can be no doubt of the accuracy of this statement; but it is questionable whether the same remark is applicable to the chlorophyll which first separates, and which is reserved in the British process. (See *Extractum Aconiti*, page 1127.) Mr. Brande states that one cwt. of fresh belladonna yields from 4 to 6 pounds of extract. According to M. Recluz, nearly ten parts may be obtained from one hundred. The best extract is brought chiefly from England; but Mr. Alfred Jones has found that it may be prepared of equally good quality from the plant grown in the United States. (*Am. Journ. of Pharm.*, xxiv. 108.) It has usually a dark-brown colour, a slightly narcotic not unpleasant odour, a bitterish taste, and a soft consistence which it long retains. Asparagin has been found in this extract. (*Journ. de Pharm.*, xxi. 178.)

Its medical properties and uses have been detailed under the head of Belladonna. A few words in relation to its mode of application may be proper here. For the dilatation of the pupil, it is either mixed with water to the consistence of cream and rubbed on the brow and eyelids, or dissolved in water and dropped into the eye. In rigidity of the os uteri, it is applied at intervals to the neck of the uterus, mixed with simple ointment in the proportion of two drachms to an ounce; but care must be taken not too powerfully to affect the system; and the preparation, therefore, should be used in a small quantity at first. In irritability of the bladder, chordee, spasm of the urethra, and painful constriction of the rectum, it may either be rubbed in the form of ointment upon the perineum, along the urethra, &c., or may be used in the form of enema; but care is requisite not to introduce it too freely into the bowel. It is sometimes smeared upon the bougie, mixed with oil, in the treatment of stricture of the urethra. In the form of ointment it has been beneficially employed in phymosis and paraphymosis, and in that of plaster or ointment, in local neuralgic or rheumatic pains. (See *Emplastrum Belladonnæ.*) The dose of the extract is uncertain on account of its variable strength. The best plan is to begin with one-quarter or one-half of a grain, repeated two or three times a day, and gradually to increase the dose till the effects of the medicine are experienced. To a child two years old not more than one-twelfth of a grain should be administered at first.

Off. Prep. Emplastrum Belladonnæ, *Br.;* Unguentum Belladonnæ. W.

EXTRACTUM BELLADONNÆ ALCOHOLICUM. *U. S. Alcoholic Extract of Belladonna.*

"Take of Belladonna Leaf, in fine powder, *twenty-four troyounces;* Alcohol *four pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and moisten the powder with a pint of the mixture; then pack it firmly in a conical percolator, and gradually pour upon it the remainder of the mixture. Continue the percolation with Diluted Alcohol until six pints of tincture have passed. Lastly, evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

This is a good preparation, though less necessary than some other spirituous

extracts of the narcotic plants; as the inspissated juice, or common extract of belladonna, can generally be procured of good quality. It is one of the officinals of the French Codex. The dose to begin with is half a grain.

Off. Prep. Emplastrum Belladonnæ, *U. S.* W

EXTRACTUM CALUMBÆ. *Br. Extract of Calumba.*

"Take of Calumba Root, cut small, *one pound* [avoirdupois]; Distilled Water *four pints* [Imperial measure]. Macerate the Calumba with two pints of the Water for twelve hours, strain and press. Macerate again with the same quantity of Water, strain and press as before. Mix and filter the liquors, and evaporate them by the heat of a water-bath until the extract is of a suitable consistence for forming pills." *Br.*

We prefer the Br. process of 1864, in which proof spirit was employed as a menstruum. As proof spirit takes up all the active matter of columbo, leaving the starch and albumen behind, the extract prepared according to that formula had, in a comparatively small bulk, all the powers of the root, except those of the small proportion of volatile oil which may be dissipated in the process. In the present process, though the starch is left behind, the albumen is taken up, and adds to the bulk of the extract. Besides, the alcoholic preparation has the advantage of requiring less heat in the evaporation, and consequently of retaining more of the volatile oil in the product. Its only disadvantage is its greater costliness. The extract may be given in the dose of from five to fifteen grains three times a day. W.

EXTRACTUM CANNABIS PURIFICATUM. *U. S.* EXTRACTUM CANNABIS INDICÆ. *Br. Purified Extract of Hemp. Extract of Indian Hemp.*

"Take of Extract of Hemp *two troyounces;* Alcohol *a sufficient quantity.* Rub the Extract with two fluidounces of Alcohol until they are thoroughly mixed; and, having added twelve fluidounces of Alcohol, allow the mixture to macerate for twenty-four hours. Then filter the tincture through paper, passing sufficient Alcohol, through the filter, to exhaust the dregs completely. Lastly, by means of a water-bath, at a temperature not exceeding 160°, evaporate to dryness." *U. S.*

"Take of Indian Hemp, in coarse powder, *one pound* [avoirdupois]; Rectified Spirit *four pints* [Imperial measure]. Macerate the Hemp in the Spirit for seven days, and press out the tincture. Distil off the greater part of the Spirit, and evaporate what remains by a water-bath to the consistence of a soft extract." *Br.*

These are not identical preparations; the U. S. purified extract being made from the impure extract imported from India, the British extract from the dried plant. It is probable that the former would be found most efficient.

Prof. Procter has investigated the subject of the tests for the purified extract or resin, and come to the following conclusions. Its peculiar odour when moderately heated, its indifference to alkalies, and its solubility in alcohol, ether, chloroform, benzole, and oil of turpentine are characteristic though not entirely distinctive properties. The best test, he thinks, is nitric acid (sp. gr. 1 38), which acts slowly when cold, but with heat rapidly, evolving red fumes, and converting the resin into an orange-red resinoid substance, which, when washed and dried, closely resembles gamboge in colour. (*Proceed. of the Am. Pharm. Assoc.*, A.D. 1864.)

For remarks in relation to the uses and doses of this preparation, see *Extractum Cannabis*, in *Part* I. (*page* 392). It is no doubt of more uniform strength than the crude extract, but cannot always be relied on as equable in this respect, and therefore should be prescribed with caution in relation to the dose.

Off. Prep. Tinctura Cannabis, *U. S.;* Tinctura Cannabis Indicæ, *Br.* W.

EXTRACTUM CINCHONÆ. *U. S. Extract of Cinchona.*

"Take of Yellow Cinchona, in fine powder, *twelve troyounces;* Alcohol *four pints;* Water *a sufficient quantity.* Introduce the powder, previously mixed

with three fluidounces of Alcohol, into a conical glass percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid ceases to pass, pour upon the residue sufficient Water to keep its surface covered, until four pints of tincture have passed. Set this aside, and continue the percolation until six pints of infusion are obtained. Distil off the alcohol from the tincture, and evaporate the infusion until the liquids respectively are brought to the consistence of thin honey; then mix them, and evaporate to the proper consistence." *U. S.*

The yellow or Calisaya bark is selected for this preparation, as it can always be relied on as efficient. By this process all the virtues of the bark are extracted; the parts soluble in alcohol being first taken up, and afterwards those in water, and the tincture and infusion thus obtained separately. This proceeding has the great advantage that no more heat is necessary to evaporate the tincture than the alcoholic menstruum requires; while, if the two liquids were mixed, it would be necessarily subjected to a longer continuance if not a higher degree of the heat; and the advantage is the greater as most of the active matter is extracted in the first percolation with alcohol. If proper care be taken in executing the process, both in relation to the percolation, and the avoidance of too high a temperature, the extract will fully represent the virtues of the bark.

In relation to this process, Dr. Squibb, though stating that it yields a very good extract, considers it capable of improvement. Three fluidounces of alcohol, directed to be mixed with the powder previously to its introduction into the percolator, is insufficient to moisten the cinchona for packing. In a formula of his own for the extract he first mixes sixteen ounces of cinchona with thirty fluidounces of alcohol, and, having allowed the mixture to stand for half an hour in a covered vessel, then pours it into the glass funnel, and proceeds to percolate with alcohol, as in the officinal process. The subsequent percolation with water to obtain an infusion he considers entirely useless, as very little that is of any value is extracted; the cinchona having in effect been exhausted by the alcohol; or at least it would be so if the percolation were carried somewhat further. Hence in his formula he omits the water except merely for displacing the alcohol, and uses a somewhat larger proportion of alcohol. Dr. Squibb thinks that the extract is improved by a little glycerin, and consequently adds a proportion equivalent to six troy drachms to the extract while yet hot after the evaporation, and rubs them well together. (*Pharmacy of the Cinchonas*, p. 25.)

The former extracts of cinchona of the British Colleges are all omitted in the new British Pharmacopœia, which directs in their place a fluid extract, under the name of *Extractum Cinchonæ Liquidum*, which will be treated of among the Fluid Extracts.

A very good extract of bark was formerly prepared, in the shops of Philadelphia, by macerating cinchona for a considerable length of time in a large proportion of water, and slowly evaporating the infusion, by a very moderate heat, in large shallow dishes placed upon the top of a stove. Before the use of sulphate of quinia had superseded that of most other preparations of bark, we employed this extract with success in the treatment of intermittents, and found ten grains of it equivalent to nearly a drachm of the powdered cinchona.

The extract should always be brought to the hard dry state in which it may be pulverized; as it is thus less apt to be injured by exposure, and in the state of powder may be more uniformly incorporated with other substances. Though directed officinally to be prepared from the yellow or Calisaya bark, it would no doubt be equally efficient if made from the red.*

* *Quinium.* Under this name a preparation has had some reputation in Europe, made by mixing quinia and cinchonia barks in such proportion that there should be about two parts of the former alkaloid to one of the latter, with half their weight of slaked lime, exhausting the mixture with alcohol, and then distilling and evaporating to dryness. The resulting *quinium* should yield one-third of its weight of the two alkaloids. The dose is three grains. The disadvantage of this as of all the amorphous preparations of the cinchona alkaloids, is the want of that protection against adulteration which is afforded by the crystalline form of the pure principles. (See *Am. Journ. of Pharm.*, Sept. 1858, p. 400.)—*Note to the twelfth edition.*

Medical Uses. The extract of Peruvian bark is at present much less employed than before the discovery of quinia. It is still, however, occasionally prescribed as a tonic in combination with other medicines; and, as it possesses, when properly prepared with a spirituous menstruum, almost all the active principles as they exist in the bark itself, it may be used in preference to the sulphate of quinia, whenever it is supposed that the latter is incapable of exerting all the curative influence of cinchona. We are told, however, that, on account of the high price of Calisaya bark, much of the extract as at present in the shops is prepared from inferior varieties. The dose is from ten to thirty grains, equivalent to about a drachm of the powdered bark. W.

EXTRACTUM COLCHICI. *Br. Extract of Colchicum.*

"Take of Fresh Colchicum Corms, deprived of their coats, *seven pounds* [avoirdupois]. Crush the Corms; press out the juice; allow the feculence to subside, and heat the clear liquor to 212°; then strain through flannel, and evaporate by a water-bath, at a temperature not exceeding 160°, to a suitable consistence for forming pills." *Br.*

There scarcely seems to be occasion for both this and the following extract. The dose is one or two grains.

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims or more. It is made by expressing the fresh bulb, allowing the juice to stand for forty-eight hours that the feculent matter may subside, then adding one-quarter of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering. W.

EXTRACTUM COLCHICI ACETICUM. *U.S., Br. Acetic Extract of Colchicum.*

"Take of Colchicum Root, in moderately fine powder, *twelve troyounces;* Acetic Acid *four fluidounces;* Water *a sufficient quantity.* To the Acetic Acid add a pint of Water, and mix the resulting liquid with the Colchicum Root. Transfer the mixture to a conical glass percolator, and pour Water gradually upon it until the liquid passes with little or no taste. Lastly, evaporate the liquid, in a porcelain vessel, to the proper consistence." *U. S.*

In the British Pharmacopœia this extract is directed to be prepared as the preceding, except that *six fluidounces* of Acetic Acid (*Br.*) are to be added to the crushed corms before expression, and that the strained liquor is to be evaporated to the consistence of a soft extract.

As the fresh colchicum bulb is rarely to be had in this country, the U. S. Pharmacopœia employs the dried bulb; and its process, if properly conducted, will afford a very efficient extract. Some inconveniences are experienced in preparing the extract, according to the London process, from the recent bulb by expression, which would seem to render the U. S. process under all circumstances preferable. (*Pharm. Journ.*, xiii. 62.)

The use of the acetic acid, in this preparation, is to render more soluble the alkaline principle upon which the virtues of meadow-saffron are thought to depend. The acetic extract of colchicum is highly commended by Sir C. Scudamore, who prefers it made by evaporating, to the consistence of honey, a saturated acetic infusion of the dried bulb. (*Lond. Med. Gazette*, Dec. 10, 1841.) The dose of the extract is one or two grains, to be repeated two or three times a day, and increased if necessary. W.

EXTRACTUM COLOCYNTHIDIS ALCOHOLICUM. *U.S. Alcoholic Extract of Colocynth.*

"Take of Colocynth *forty-eight troyounces;* Diluted Alcohol *a sufficient quantity.* Dry the Colocynth, and, having removed the seeds, and reduced it to coarse powder by grinding or bruising, macerate it in eight pints of Diluted Alcohol for four days, with occasional stirring; then express strongly, and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and pour Diluted Alcohol

upon it, until the tincture and expressed liquid, taken together, measure sixteen pints. Mix the tincture with the expressed liquid, and, having recovered from the mixture ten pints of alcohol by distillation, evaporate the residue to dryness by means of a water-bath. Lastly, reduce the dry mass to powder, and keep it in a well-stopped bottle. The Extract obtained by this process weighs about seven troyounces." *U. S.*

Colocynth should be deprived of its seeds, as directed by the U. S. Pharmacopœia, before being submitted to the action of the menstruum. Dr. Duncan found half a pound of colocynth to contain 2770 grains of seeds, which, boiled by themselves, yielded almost nothing to water. Dr. Squibb found selected fruits to yield from 25·8 to 34 per cent. of medullary part; and this, when well exhausted by diluted alcohol, to yield 60·7 to 60·8 per cent. of dry extract; while from the whole fruit, including pulp and seeds, from 15·69 to 20·6 per cent. was obtained according to the degree of dryness. (*Am. Journ. of Pharm.*, Jan. 1857, p. 98.) Boiling water extracts so much pectic acid and mucilage from colocynth, that the decoction or hot infusion gelatinizes on cooling; and the extract made by means of it is loaded with inert matter, and, besides, is apt to become mouldy, or so tough and hard as to resist trituration and formation into pills. Hence the London College, following in this respect the French Codex, directed, in the last edition of its Pharmacopœia, maceration with cold water; but diluted alcohol has been found to be a much better menstruum, and has been adopted in the U. S. process; while, in the British Pharmacopœia, the simple extract has been discarded altogether. The chief, if not exclusive use of the alcoholic extract is in the preparation of the compound extract.

Off. Prep. Extractum Colocynthidis Compositum, *U. S.* W.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. *U. S.*, *Br.* *Compound Extract of Colocynth.*

"Take of Alcoholic Extract of Colocynth, in fine powder, *three troyounces and a half;* Socotrine Aloes, in fine powder, *twelve troyounces;* Resin of Scammony, in fine powder, *three troyounces;* Cardamom, in fine powder, *a troyounce;* Soap, in fine powder, *three troyounces.* Mix the powders thoroughly, and keep the mixture in a well-stopped bottle." *U. S.*

"Take of Colocynth Pulp *six ounces;* Extract of Socotrine Aloes *twelve ounces;* Resin of Scammony *four ounces;* Hard Soap, in powder, *three ounces;* Cardamom Seeds, in fine powder, *one ounce;* Proof Spirit *one gallon* [Imperial measure]. Macerate the Colocynth in the Spirit for four days; press out the tincture, and distil off the Spirit; then add the Aloes, Scammony, and Soap, and evaporate by a water-bath until the extract is of a suitable consistence for forming pills, adding the Cardamoms towards the end of the process." *Br.* The ounce employed in this process is the avoirdupois.

The present U. S. formula differs from that of 1850, in taking the alcoholic extract of colocynth already prepared, instead of directing its preparation from the colocynth, and in substituting resin of scammony for the scammony itself. The former provision ensures uniformity of result so far as the colocynth is concerned; whereas, by the old formula, this was impossible, owing to the variable quality of the colocynth employed, unless an unusual amount of care was taken in its selection. The second change contributes to the same result of uniformity; because the resin of scammony is very nearly of equable strength, while scammony is notoriously otherwise; and it has the additional advantage of yielding a stronger extract, as the resin is much more energetic in an equal dose than the crude drug as ordinarily found in the market. The object of the soap in this formula is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the liquors of the stomach. It may possibly also serve the purpose of qualifying the action of the aloes. In the U. S. process the extract is in the form of powder, which is very convenient for admixture with other substances; while, if given uncombined, it may be readily made into pills by suitable additions. The alternative of using the

scammony or its resin, in the first British formula, which appeared to us very objectionable, has been abandoned in the present edition, and the resin only directed. It has been objected to the present U. S compound extract, that it is apt to gripe in consequence of deficiency in the proportion of the aromatic ingredient; and the addition of some aromatic oil, as oil of cloves, has been recommended. The plan of having the powders simply mixed is liable to the objection, that the mixture is apt not to be thoroughly effected, so as to obtain a uniform result; and hence it is suggested, in accordance with Dr. Squibb's plan, to melt together all the ingredients unpowdered, except the cardamom, and when the mixture is thoroughly made, to stir in the powdered aromatic. (Procter, *Am. Journ. of Pharm.*, Jan. 1867, p. 20.)

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, &c., with one or more of which it is often united in prescription. In such combination it is much employed whenever an active cathartic is desirable, particularly in the commencement of fevers and febrile complaints, in congestion of the liver or portal system, and in obstinate constipation. In small doses it is an excellent laxative in that state of habitual costiveness, depending on a want of the due irritability of the bowels, which often occurs in old people. The dose is from five to thirty grains, according to the effect to be produced, and the susceptibility of the bowels. A very eligible combination is the compound cathartic pill of the U. S. Pharmacopœia. We are informed that much of the extract sold in this country is made with inferior scammony and aloes, and an insufficient proportion of colocynth, so that it is comparatively inert. Cheap compound extract of colocynth should be looked on with suspicion, and the apothecary should prepare it for himself.*

Off. Prep. Pilulæ Catharticæ Compositæ, *U. S.* W.

EXTRACTUM CONII. *U. S.*, *Br.* *Extract of Hemlock.*

"Take of Hemlock, fresh, *twelve troyounces*. Bruise the Hemlock in a stone mortar, sprinkling on it a little water, and express the juice, then, having heated this to the boiling point, filter it, and evaporate to the proper consistence, either in a vacuum with the aid of heat, or in shallow vessels, at the ordinary temperature, by means of a current of air, directed over the surface of the liquid." *U. S.*

The directions of the *British Pharmacopœia* for this extract are precisely the same as those for the extract of aconite, the fresh leaves and young branches of conium being used.

The most important point in the preparation of this extract is to evaporate the juice without an undue degree of heat. At a temperature of 212° or upwards, its active principle undergoes rapid decomposition, being converted into resinous matter and ammonia. This is detected by the operator by the ammoniacal odour mixed with that which is peculiar to the plant. The juice always to a certain extent undergoes this decomposition when evaporated over a fire, and is not exempt from it even when the heat is regulated by a water-bath. Hence the propriety of the directions in the U. S. and British Pharmacopœias. An excellent plan in the evaporation is to conduct it first in a vacuum, and afterwards in shallow vessels with a current of air at common temperatures. By the direction to heat the juice to the boiling point, or 200° (*Br.*), and then to filter, whereby the inert albumen is coagulated, and, with the equally inert chlorophyll and vegetable fibre, is separated from the liquid before evaporation, the extract is procured in a more concentrated state, and, besides, deprived of substances which might favour its decomposition. Long-continued exposure to the air is

* See in the *American Journal of Pharmacy* for March, 1857 (xxix. 97), and in the *Proceedings of the Am. Pharm. Assoc.*, 1858 (p. 411), some useful practical observations by Dr. E. R. Squibb, upon the best method of preparing this extract, so as to secure uniformity and efficiency.

productive of the same result as too much heat, so that old extracts are frequently destitute of activity. (*Journ. de Pharm.*, xxii. 416.) No one of the extracts is more variable in its qualities than this. The season at which the herb is collected, the place and circumstances of its growth, the method of preparing the extract, are all points of importance, and are all too frequently neglected. (See *Conii Folia.*) In this country the process has often been carelessly conducted; and large quantities of an extract, prepared by boiling the plant in water and evaporating the decoction, have been sold as the genuine drug. The apothecary should always prepare the extract himself, or procure it from persons in whom he can have confidence. That imported from London has usually been considered the best; but we have seen and tried the extract prepared by the Messrs. Tilden & Co., of New York, by evaporation in vacuo at a low heat, and have found it superior to any that we had previously employed. It is not improbable that, as suggested to us by Professor Procter, the addition of a portion of acetic acid to the juice, before evaporation, might tend to fix the conia, and enable it better to resist the influence of heat than its native combination. The activity of any specimen of the extract may be in some measure judged of by rubbing it with potassa, which, disengaging the *conia* and rendering it volatile, gives rise to the peculiar mouse-like odour of that principle. If no odour be evolved under these circumstances, the extract may be deemed inert.

The extract of hemlock prepared without separating the chlorophyll has a fresh olive or green colour, but, according to the U. S. process, is brownish. It should have a strong narcotic, somewhat fetid odour, and a bitterish saline taste. According to Brande, from three to five pounds are obtained from one cwt. of the leaves. M. Recluz got rather more than an ounce from sixteen ounces. Of the medical properties and application of this extract, we have spoken under the head of Conii Folia. The dose is two grains, two, three, or four times a day, to be gradually increased till evidences of its action upon the system are afforded. It may be administered in pill or solution.

Off. Prep. Pilula Conii Composita, *Br.;* Vapor Coniæ, *Br.* W.

EXTRACTUM CONII ALCOHOLICUM. *U. S. Alcoholic Extract of Hemlock.*

"Take of Hemlock, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour Diluted Alcohol upon it until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate this liquid, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

This is one of the French officinal extracts, and, when well made from recently and carefully dried leaves, is a good preparation. The same caution is requisite in evaporating in this case as in that of the inspissated juice or common extract. It will be noticed that care is taken in the formula to prevent injury from too great a heat, by first passing alcohol, which forms a highly concentrated tincture, and allowing this to evaporate spontaneously to three fluidounces, which is not added to the remainder until but little of the menstruum remains; and the process is completed at the low heat of 120°. This caution is necessary from the great facility with which conia is decomposed by heat. The proportion of extract yielded by dried hemlock, by percolation with alcohol, is, according to Messrs. Vielguth and Nentwich, 21·3 per cent. (See *Am. Journ. of Pharm.*,

May, 1859, p. 237.) The dose, to begin with, is one or two grains, to be increased if necessary. W.

EXTRACTUM DIGITALIS ALCOHOLICUM. *U. S.* *Alcoholic Extract of Digitalis.*

"Take of Digitalis, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour Diluted Alcohol upon it until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate this liquid, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

This is a new officinal of the U. S. Pharmacopœia, though less needed than many others, because the dose of digitalis itself is small; and nothing is gained on the point of equability of strength; as the really active part of digitalis constitutes but a small proportion even of the extract, and might be altogether wanting without observably affecting its bulk. The same caution is used, in preparing this extract, against the injurious effects of heat as in the instance of the extract of conium. The skill, exhibited by the revisers of the Pharmacopœia in the application of the process of percolation to pharmaceutical purposes, is evinced nowhere more strongly than in the directions for preparing extracts, fluid extracts, and oleoresins. The alcoholic extract of digitalis contains all the virtues and may be used for all the purposes of the powdered leaves. According to Messrs. Vielguth and Nentwich, the amount of alcoholic extract obtained from dried digitalis by cold displacement is 27·1 per cent. (See *Am. Journ. of Pharm.*, May, 1859, p. 237.) The dose, therefore, of this extract to begin with should not exceed one-fourth of a grain. W.

EXTRACTUM DULCAMARÆ. *U. S.* *Extract of Bittersweet.*

"Take of Bittersweet, in moderately fine powder, *twelve troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Bittersweet with four fluidounces of Diluted Alcohol, pack it in a conical percolator, and pour Diluted Alcohol gradually upon it until the tincture passes but slightly impregnated with the properties of the Bittersweet. Distil off the alcohol from the tincture until reduced to one-half; then strain, and, by means of a water-bath, evaporate to the proper consistence." *U. S.*

This preparation is well known on the continent of Europe, but comparatively little used in the United States or Great Britain. The substitution, in the late revision of the Pharmacopœia, of diluted alcohol for water as the menstruum is a decided improvement. The dose is from five to ten grains; but much more may be given with safety. W.

EXTRACTUM GENTIANÆ. *U. S., Br.* *Extract of Gentian.*

"Take of Gentian, in moderately coarse powder, *twelve troyounces;* Water *a sufficient quantity.* Moisten the Gentian with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the properties of the Gentian. Boil the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence." *U. S.*

"Take of Gentian Root, sliced, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure]. Infuse the Gentian in the Water for two hours, boil for fifteen minutes; pour off, press, and strain. Then evaporate the liquor by a water-bath until the extract is of a suitable consistence for forming pills." *Br.*

The U. S. plan of percolation with cold water is admirably adapted to the extraction of the active matter of gentian, and even the British method of maceration with hot water is much better than the old method of decoction. By the use of cold water starch and pectic acid are left behind, while any albumen that may be taken up is got rid of by the boiling and straining.

The extract, however, may be advantageously made by macerating the root in two parts of water for thirty-six hours, then expressing in a powerful press, again macerating with additional water, and in like manner expressing, and evaporating the united expressed liquors. MM. Guibourt and Cadet de Vaux obtained by maceration in cold water an extract not only greater in amount, but more transparent, more bitter, and possessing more of the colour and smell of the root than that prepared by decoction. Guibourt attributes this result to the circumstance that, as gentian contains little if any starch, it yields nothing to boiling which it will not also yield to cold water; while decoction favours the combination of a portion of the colouring matter with the lignin. But this opinion requires modification, now that it is understood that gentian contains pectic acid, which water will extract when boiling hot, but not when cold. For observations in relation to the best modes of evaporation in the formation of extracts, the reader is referred to *page* 1123. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian is nearly inodorous, very bitter, of a dark-brown colour approaching to black, shining, and tenacious. It is frequently used as a tonic, in the form of pill, either alone or in connection with metallic preparations. The dose is from ten to thirty grains. W.

EXTRACTUM HÆMATOXYLI. *U. S., Br. Extract of Logwood.*

"Take of Logwood, rasped, *twelve troyounces;* Water *eight pints.* Boil down to four pints, and strain the decoction while hot; then evaporate to dryness." *U. S.*

"Take of Logwood, in fine chips, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure]. Infuse the Logwood in the water for twenty-four hours, then boil down to one-half, strain, and evaporate to dryness by a water-bath, stirring with a wooden spatula. Iron vessels should not be used." *Br.*

This is one of the few instances in which decoction in the preparation of extracts is not considered objectionable. Iron vessels should not be employed in the process, in consequence of the presence of tannic acid. The evaporation should be carried so far that the extract may be dry and brittle when cold. About 20 lbs. of it are obtained from one cwt. of logwood. (*Brande.*) It is of a deep-ruby colour, and an astringent, sweetish taste, and has all the medical virtues of the wood. If given in pills, these should be recently made, as, when long kept, they are said to become so hard as sometimes to pass unchanged through the bowels. The extract, however, is best administered in solution. The dose is from ten to thirty grains. This extract is said to be prepared largely in Yucatan and other parts of Mexico. W.

EXTRACTUM HELLEBORI ALCOHOLICUM. *U. S.* Extractum Hellebori. *U. S.* 1850. *Alcoholic Extract of Black Hellebore. Extract of Hellebore.*

"Take of Black Hellebore, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. To this add the three fluid-

ounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

In consequence, probably, of the injurious influence of heat upon black hellebore, the watery extract prepared by decoction is little if at all stronger than the root. The process of percolation with cold spirit was, therefore, adopted in the U. S. Pharmacopœia of 1850, and has been retained with improvement in the present edition; and, if proper care be taken to conduct the evaporation at as low a temperature, and with as little exposure to the air as possible, an efficient extract will be obtained. Any resin which may be deposited during the evaporation should be separated from the sides of the vessel, and mixed with the rest. If the hellebore itself be of good quality, the extract will operate as a drastic purge in the dose of from five to ten grains.

The former French Codex contained a process for preparing the extract of hellebore, according to the method of Bacher. Two pounds of the root and half a pound of carbonate of potassa are digested, with a moderate heat, for twelve hours, in eight pounds of alcohol of 22° B; the tincture is strained with expression; the residuum is again digested with eight pounds of white wine for twenty-four hours; the wine is expressed, and, having stood four hours to settle, is decanted; the liquors are then mixed, and with a gentle heat evaporated to the consistence of an extract. One ounce of this extract, mixed with the same quantity of myrrh, and with ten scruples of the powdered leaves of Centaurea benedicta, and made into pills of one grain each, constitutes the preparation known as the *tonic pills of Bacher*, formerly much used in amenorrhœa and dropsy, and probably not without advantage, especially in the former of these diseases. The dose is from ten to twenty pills during the day. An additional quantity of diluted alcohol might, without disadvantage, be substituted for the wine in the preparation of this extract. W.

EXTRACTUM HYOSCYAMI. *U. S.*, *Br.* *Extract of Henbane.*

"Take of Henbane Leaf, fresh, *twelve troyounces*. Bruise the Leaf in a stone mortar, sprinkling on it a little water, and express the juice; then, having heated this to the boiling point, strain, and evaporate to the proper consistence." *U. S.*

In the British Pharmacopœia this extract is prepared from "the fresh Leaves and Young Branches of Hyoscyamus" in the same manner precisely as Extract of Aconite. (See *Extractum Aconiti.*)

MM. Solon and Soubeiran have shown that the insoluble matter separated from the expressed juice of henbane by filtering, and that coagulated by heat, are nearly if not quite inert; so that the juice may be usefully clarified before evaporation. (*Amer. Journ. of Pharm.*, viii 228.) The retention of the chlorophyll, however, as provided for in the British formula, is thought to be advantageous. Extract of Henbane has been chiefly derived from England, but it is at present prepared by Messrs. Tilden & Co., of New York, by the vacuum process. Mr. Brande says that one cwt. of the fresh herb affords between four and five pounds. M. Recluz obtained about one part from sixteen.

The extract is of a dark-olive colour, of a narcotic rather unpleasant odour, and a bitterish, nauseous, slightly saline taste. It retains its softness for a long time; but at the end of three or four years becomes dry, and exhibits, when broken, small crystals of nitrate of potassa and chloride of sodium. (*Recluz.*) Like all the inspissated juices, it is of variable strength, according to its age, the care used in its preparation, and the character of the leaves from which it was procured. (See *Hyoscyamus.*)* In its use, therefore, it is advisable to begin with

* Much depends on the choice of the leaves; and too little attention is paid to this point. In reference to the biennial plant, there seems to be no doubt that the leaves of the second year are much more efficacious than those of the first, and should, therefore, always be selected. It is stated under Hyoscyamus, in the first part of this work, that the leaves should be gathered soon after the plant has flowered. Mr. Charles Cracknell gives more particular directions. He thinks that the plant is in a fit state for collection only during a very short period; when the flowers at the top are blown, but have not yet begun to fade, and the seed-vessels and seeds which have been formed are still soft

a moderate dose, two or three grains for instance, and gradually to increase the quantity till some effect is experienced, and the degree of efficiency of the particular parcel employed is ascertained. It is usually given in pill. It is sometimes used externally for the same purposes as extract of belladonna.

Off. Prep. Pilula Colocynthidis et Hyoscyami, *Br.* W.

EXTRACTUM HYOSCYAMI ALCOHOLICUM. *U.S. Alcoholic Extract of Henbane.*

"Take of Henbane Leaf, recently dried and in moderately fine powder, *twenty-four troyounces;* Alcohol *four pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and moisten the powder with a pint of the mixture; then pack it firmly in a conical percolator, and gradually pour upon it the remainder of the mixture. Continue the percolation with Diluted Alcohol until the tincture measures six pints. Lastly, evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

The alcoholic extract of henbane, if prepared from recently dried leaves, is thought to be more uniform and powerful than the inspissated juice or common extract. It is one of the preparations of the French Codex. The dose is one or two grains, to be gradually increased until its effects are obtained. W.

EXTRACTUM IGNATIÆ ALCOHOLICUM. *U.S. Alcoholic Extract of Ignatia.*

"Take of Ignatia, in fine powder, *twelve troyounces;* Alcohol *a sufficient quantity.* Mix the Ignatia with four fluidounces of Alcohol, and allow the mixture to stand for an hour. Then introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until three pints of tincture have slowly passed. Distil off the Alcohol, by means of a water-bath, until the tincture is reduced to half a pint, and evaporate this to the proper consistence." *U. S.*

This was newly introduced into the present edition of the U. S. Pharmacopœia, not so much because the preparation is needed; for it is essentially the same in remedial properties and applications as the extract of nux vomica; as in order to give due officinal sanction to a preparation already in popular use, and, by regulating it duly, to prevent serious consequences from so powerful a medicine.* For the uses of the extract the reader is referred to the article on Ignatia in *Part* I. The dose is from half a grain to three times that quantity, to be repeated three times a day until its effects begin to be experienced. W.

EXTRACTUM JALAPÆ. *U.S., Br. Extract of Jalap.*

"Take of Jalap, in moderately fine powder, *twelve troyounces;* Alcohol *four pints;* Water *a sufficient quantity.* Introduce the powder, previously mixed with three fluidounces of Alcohol, into a conical percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid ceases to pass, pour upon the residue sufficient water to keep its surface covered, until four pints of tincture have passed. Set this aside, and continue the percolation until six pints of

and juicy. For other observations on the preparation of this extract, see a paper by Mr. Cracknell in the *Am. Journ. of Pharm.* (xxiii. 245), from the *Pharm. Journ.*, March, 1851.

An important contribution to our knowledge, as to the proper choice of the parts of this plant to be expressed, has been made by Mr. T. B. Groves, of England. Whatever may be the case with those plants, such as aconite, the roots of which are active, and in which the juice, containing the active matter, on its way from the leaves to the root, might be supposed to exist in the young stems, this does not appear to be the case with the Hyoscyamus; and, accordingly, an extract obtained by inspissating the juice of the stems was found altogether inferior to another obtained in like manner from the leaves, being not only less in amount, but less bitter and odorous, and more saline, showing that it contained more of the ordinary salts of the plant, and less of its active matter. (*Pharm. Journ.*, Jan. 1862, p. 376.)—*Note to the tenth and twelfth editions.*

* According to Prof. Procter, a portion of fixed oil is extracted by the alcohol, which separates when the concentrated tincture is allowed to stand, and, being in itself inert, might be rejected with advantage, care being taken to wash it first with weak alcohol, and add the washings to the liquid. The same result does not happen when diluted alcohol is used as the menstruum; as this does not take up the oil.

infusion have been obtained. Distil off the alcohol from the tincture, and evaporate the infusion until the liquids respectively have been brought to the consistence of thin honey; then mix them, and evaporate to the proper consistence." *U. S.*

"Take of Jalap, in coarse powder, *one pound* [avoirdupois]; Rectified Spirit *four pints* [Imperial measure]; Distilled Water *one gallon* [Imp. meas.]. Macerate the Jalap in the Spirit for seven days; press out the tincture, then filter, and distil off the Spirit, leaving a soft extract. Again macerate the residual Jalap in the Water for four hours, express, strain through flannel, and evaporate by a water-bath to a soft extract. Mix the two extracts, and evaporate, at a temperature not exceeding 140°, until it has acquired a suitable consistence for forming pills." *Br.*

Jalap contains a considerable quantity of starch, which is extracted by decoction, but left behind by cold water; and, as this principle serves only to impede the filtration or straining, and augment the bulk of the extract, without adding to its virtues, cold water is very properly used in both the *U. S.* and *Br.* processes. The use both of alcohol and water has been deemed necessary, in order to extract all the medicinal qualities of the drug; and they are employed successively, under the impression that the previous removal of the resin by the former facilitates the action of the latter.* The use of percolation, as directed by the U. S. Pharmacopœia, enables the cold water to extract the soluble parts without the long maceration which would otherwise be necessary. According to Cadet de Gassicourt, water at ordinary temperatures, and in the old mode, acts so slowly, that fermentation takes place before the active matter is all dissolved. Hence, if the extract be prepared without percolation, the residuum, after the tincture has been decanted, should be digested with water at a heat of about 90° or 100° F., which, while it is insufficient for the solution of the starch, enables the solvent to take up the active matter with sufficient rapidity.

One cwt. of jalap affords, according to Mr. Brande, about fifty pounds of aqueous extract and fifteen of resin. The product of the former is somewhat less by infusion than decoction; and the extract is proportionably stronger.

There is reason to believe, as we have been informed on good authority, that what is sold for extract of jalap is sometimes prepared from tubers which had been previously exhausted of their resin by alcohol; and a spurious substance has been offered in considerable quantities in our markets for extract of jalap, which, on examination by Messrs. Ch. Bullock and Ed. Parrish, proved to owe its purgative property to 42 per cent. of gamboge. (*Am. Journ. of Pharm.*, March, 1862, p. 113.)

Extract of jalap is of a dark-brown colour, slightly translucent at the edges, and tenacious when not perfectly dry. It contains the resin and gummy extractive, and, consequently, has all the medical properties of the root; but it is not often exhibited alone, being chiefly used as an ingredient of purgative pills, for which it is adapted by its comparatively small bulk. It is most conveniently kept for use in the form of powder, which, however, is apt to attract moisture and to aggregate into a solid mass, unless carefully excluded from the air. The dose is from ten to twenty grains, or rather more than half that of jalap.†

Off. Prep. Pilulæ Cathartice Compositæ, *U. S.* W.

* Mr. A. B. Taylor has satisfactorily determined that the substance which water will extract from jalap, previously exhausted by alcohol, has no observable influence on the system; having taken 240 grains of the matter thus extracted without effect. (*Proceedings of the Am. Pharm. Association*, A.D. 1864, p. 215.) But it does not follow that this material is useless in the extract; for it is highly probable that the irritant properties of the resin, which is the real purgative principle of jalap, are so mechanically modified by association with the gum in the root as to render jalap a less irritant cathartic than its extracted resin; and that consequently the present hydro-alcoholic extract, representing the root as it does in this respect, while not less energetic, in proportional doses, as a purgative than the resin, is less apt to provoke irritation of the alimentary mucous membrane. (*Note to the thirteenth edition.*)

† *Fluid Extract of Jalap.* The following process has been proposed by Prof. Procter. Take of jalap, in coarse powder, ℥xvi; sugar ℥viij; carbonate of potassa ℥ss; alcohol,

EXTRACTUM JUGLANDIS. *U. S.* *Extract of Butternut.*

"Take of Butternut, in moderately coarse powder, *twelve troyounces;* Water *a sufficient quantity.* Moisten the Butternut with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the properties of the Butternut. Boil the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence." *U. S.*

This extract was formerly for the most part prepared by the country people, who are said to have used the bark of the branches and even the branches themselves, instead of the inner bark of the root; and to have injured the preparation by too much heat. That it should have proved uncertain in the hands of many physicians is, therefore, not a matter of surprise. It should be prepared by the apothecary, and from the inner bark of the root gathered in May or June. Experiments are yet wanting to prove that water is the best solvent of the active principles of this bark. Prof. Procter informs us that he has found an extract of the fresh bark prepared with diluted alcohol to have much more of the pungency of the bark than the officinal.

The extract of butternut is of a black colour, sweetish odour, and bitter astringent taste. In the dose of twenty or thirty grains, it acts as a mild cathartic. (See *Juglans.*) W.

EXTRACTUM KRAMERIÆ. *U. S.*, *Br.* *Extract of Rhatany.*

"Take of Rhatany, in moderately fine powder, *twelve troyounces;* Water *a sufficient quantity.* Moisten the powder with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the astringent property of the Rhatany. Heat the liquid to the boiling point, strain, and, by means of a water-bath, at a temperature not exceeding 160°, evaporate to the proper consistence." *U. S.*

"Take of Rhatany Root, in coarse powder, *one pound* [avoirdupois]; Distilled Water *a sufficiency.* Macerate the Rhatany in a pint and a half [Imperial measure] of the Water for twenty-four hours; then pack in a percolator, and add more Distilled Water, until twelve pints [Imp. meas.] have been collected, or the Rhatany is exhausted. Evaporate the liquor by a water-bath to dryness." *Br.*

In selecting a plan for the preparation of this extract, it was undoubtedly wise to adopt the mode of displacement, with cold water as the menstruum. (See *page* 516.) It is absolutely necessary to the success of the process, that the root should be well and uniformly comminuted; and the "moderately fine powder" of the U. S. Pharmacopœia is, therefore, preferable to the "coarse powder" of the British. The wood of the root yielded to Prof. Procter only 6·8 per cent. of extract, while the bark separated from the wood yielded 33 per cent. As the wood is of difficult pulverization, the inference is obvious, that, in powdering the roots, the ligneous portion may be rejected with advantage. (*Am. Journ. of Pharm.*, xiv. 270.) As a prolonged exposure of the infusion to the air is attended with the absorption of oxygen, and the production of insoluble apotheme, it is desirable that the evaporation should be conducted rapidly or in a vacuum. There scarcely appears to be occasion, in the case of rhatany, for heating and filtering the infusion before evaporation, the only use of which is to get rid of albumen, which is not among the recognized ingredients of the root.

Very inferior extracts of rhatany are often sold. Such is the South American

water, each, *q. s.* Add to the jalap one pint of a mixture consisting of two parts of alcohol and one of water, and set aside for twenty-four hours. Then put the mixture into a percolator, and pour on it diluted alcohol until half a gallon has passed. Evaporate the filtered liquid one-half, add the sugar and carbonate of potassa, and evaporate to 12 fluidounces. Put the liquid, while warm, into a pint bottle, add four fluidounces of alcohol, and mix. The carbonate of potassa renders the resin soluble in water, and probably favourably qualifies the irritating properties of the jalap. A fluidrachm of this extract would represent a drachm of jalap, so that the dose should be from 15 to 30 minims. (*Am. Journ. of Pharm.*, xxix. 108.)—*Note to the eleventh edition.*

extract, which has been occasionally imported. As the product obtained by decoction is greater than that afforded by the officinal plan, the temptation to substitute the former is not always resisted, although it has been shown to contain nearly 50 per cent. of insoluble matter. Some druggists prepare the extract with an alcoholic menstruum, with a view to the greater product; but the extract thus prepared has from 20 to 30 per cent. less of the active principle than the officinal. A substance has been shown to us, said to have been imported as extract of rhatany from Europe, which was nearly tasteless, and was plausibly conjectured to be the dried coagulated matter of old tincture of kino. Indeed, we are informed that very little of the genuine extract, prepared according to the officinal directions, is to be found in the shops. From a notice by Prof. Procter in the *Am. Journ. of Pharm.* (May, 1862, p. 209), it would appear that the rhatany now imported is much inferior to that formerly in use, having a larger proportion of wood, and yielding much less extract; and a specimen carefully manipulated by himself, gave but 9·14 per cent.

Extract of rhatany should have a reddish-brown colour, a smooth shining fracture, and a very astringent taste; and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed. The dose is from ten to twenty grains.

Off. Prep. Syrupus Krameriæ, *U. S.* W.

EXTRACTUM LACTUCÆ. *Br.* *Extract of Lettuce.*

In the British Pharmacopœia, this extract is prepared from "the Flowering Herb of Lettuce," in the same manner precisely as Extract of Aconite. (See *Extractum Aconiti.*) For the medical properties and uses of extract of lettuce the reader is referred to the article on Lettuce in *Part* I. The dose is from five to fifteen grains. W.

EXTRACTUM LUPULI. *Br.* *Extract of Hop.*

"Take of Hop *one pound* [avoirdupois]; Rectified Spirit *one pint and a half* [Imperial measure]; Distilled Water *one gallon* [Imp. meas.]. Macerate the Hop in the Spirit for seven days; press out the tincture, filter, and distil off the spirit, leaving a soft extract. Boil the residual Hop with the Water for one hour, press out the liquor, strain, and evaporate by a water-bath to the consistence of a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° until it has acquired a suitable consistence for forming pills." *Br.*

This is a great improvement on the old Lond. and Ed. process by maceration with water and evaporation. Alcohol is necessary for the exhaustion of the hop, and very cautious evaporation, to preserve the aroma in the extract. But since the discovery of the fact that the active properties of hops reside chiefly in the lupulin, the extract has been to a great extent superseded by that substance in this country, and has been little used. Lupulin may be advantageously substituted for it in all cases in which it was formerly employed. Mr. Brande says that the average yield of one cwt. of hops is 40 lbs. of the extract. The dose is from ten to thirty grains.

Under the inappropriate name of *humuline*, an extract has been prepared by first treating hops with alcohol and subsequently with water, evaporating the tincture and infusion separately, and mixing the products. (*Pharm. Journ.*, xiii. 231.) W.

EXTRACTUM MEZEREI ÆTHEREUM. *Br.* *Ethereal Extract of Mezereon.*

"Take of Mezereon Bark, cut small, *one pound* [avoirdupois]; *Rectified Spirit eight pints* [Imperial measure]; Ether *one pint* [Imp. meas.]. Macerate the Mezereon in six pints of the Spirit for three days, with frequent agitation; strain and press. To the residue of the Mezereon add the remainder of the Spirit, and again macerate for three days, with frequent agitation; strain

and press. Mix and filter the strained liquors; recover the greater part of the Spirit by distillation, evaporate what remains to the consistence of a soft extract; put this into a stopped bottle with the Ether, and macerate for twenty-four hours, shaking them frequently. Decant the ethereal solution; recover part of the Ether by distillation, and evaporate what remains to the consistence of a soft extract." *Br.*

This is the process of the present French Codex, with slight modifications, which do not affect the result. In the Codex the mezereon is exhausted by means of percolation, instead of by a double maceration; and in this respect the process is, we think, preferable, in the hands of a skilful operator. With those not experienced in percolation, it may be better to follow the British Pharmacopœia.

By the method of proceeding in the preparation of this extract the irritating properties of mezereon are concentrated in a small bulk; all the ingredients of the bark not soluble both in alcohol and in ether being excluded. For external use this is probably desirable; and the extract is therefore chiefly useful as an external irritant; for which purpose it is brought into the state of an ointment, as in the French "*pommade epispastique au garou*," or used in liniments, as in the British "*compound liniment of mustard.*" The French "pommade," which might properly be designated as *Unguentum Mezerei*, or *Ointment of Mezereon*, is prepared in the following manner.

"Take of Ethereal Extract of Mezereon *forty parts;* Lard *nine hundred parts;* White Wax *one hundred parts;* Alcohol *ninety parts.* Dissolve the Extract in the Alcohol, add the Lard and Wax, and heat moderately, with continual agitation, until the alcohol is evaporated. Pass through linen; pour into a pot, and shake until the ointment is partly cooled." (*Fr. Codex.*)

The object of this preparation is to act as an irritant agent, and especially as a dressing for issues and blistered surfaces to keep them open. For this purpose it is preferable to the ointment of cantharides, in all cases in which the latter is disposed to cause strangury. Such a preparation is much needed. An ointment of mezereon was directed in our Pharmacopœia; but was rejected at the revision for the present edition, probably on account of its inefficiency from improper mode of preparation. It would, we think, have been better to improve the process.

Off. Prep. Linimentum Sinapis Compositum, *Br.* W.

EXTRACTUM NUCIS VOMICÆ ALCOHOLICUM. *U. S.* Extractum Nucis Vomicæ. *Br.*, *U. S.* 1850. *Alcoholic Extract of Nux Vomica. Extract of Nux Vomica.*

"Take of Nux Vomica, in fine powder, *twelve troyounces;* Alcohol *a sufficient quantity.* Mix the Nux Vomica with four fluidounces of Alcohol, and allow the mixture to stand for an hour. Then introduce it into a cylindrical percolator, and gradually pour Alcohol upon it until the tincture passes without bitterness Distil off the alcohol, by means of a water-bath, until the tincture is reduced to half a pint, and evaporate this to the proper consistence." *U. S.*

"Take of Nux Vomica *one pound* [avoirdupois]; Rectified Spirit *a sufficiency.* Apply steam to the Nux Vomica until it is thoroughly softened, then dry rapidly, and reduce to fine powder. Exhaust the powder by boiling it with successive portions of the Spirit until the latter comes off nearly free from bitterness. Strain, distil off the spirit and evaporate by a water-bath to the consistence of a soft extract." *Br.*

In both the U. S. and Br. Pharmacopœias the nux vomica is directed in fine powder; but in the latter only are we told how to reduce it to that state. Another method, formerly employed by the Ed. College, was to grind it in a coffee-mill. The method of percolation in the U. S. process is preferable to that of decoction in the British, for exhausting the drug. We prefer the simple British name, which was that of our Pharmacopœia of 1850, to the more prolix one adopted in the late revision As there is no other extract of nux vomica, it appears to

us to have been an unnecessary precision to add the epithet *alcoholicum*, which renders the title more unwieldy, without making it more distinctive. This is one of the few instances in which the U. S. Pharmacopœia deems a preliminary maceration advisable. It is said that, when the extract is kept in powder, it is apt to agglutinate into a tough mass. According to Zippel, this may be prevented by adding a little water before the close of the evaporation, and then continuing the evaporation to dryness. (*Arch. der Pharm.*, July 24, 1859.)

This extract is an active preparation, though not always of uniform strength, owing to the variable proportion of strychnia in the nux vomica. M. Recluz obtained from sixteen ounces of nux vomica the average product of one ounce and a quarter. The dose of the extract is from half a grain to two grains, to be repeated three times a day.* W.

EXTRACTUM OPII. *U. S.*, *Br.* *Extract of Opium.*

"Take of Opium *twelve troyounces;* Water *five pints.* Cut the Opium into small pieces, macerate it for twenty-four hours in a pint of the Water, and reduce it to a soft mass by trituration. Express the liquid, and treat the residue with each of the four remaining pints of water successively in the same manner. Having mixed the liquids, filter the mixture, and evaporate, by means of a water-bath, to the proper consistence." *U. S.*

"Take of Opium, in thin slices, *one pound* [avoirdupois]; Distilled Water *six pints* [Imperial measure]. Macerate the Opium in two pints of the Water for twenty-four hours, and express the liquor. Reduce the residue of the Opium to a uniform pulp, macerate it again in two pints of the Water for twenty-four hours, and express. Repeat the operation a third time. Mix the liquors, strain through flannel, and evaporate by a water-bath until the extract has acquired a suitable consistence for forming pills." *Br.*

These processes are essentially the same. An advantage of the preparation is that, by the solubility of the extract in water, it affords a convenient method of obtaining quickly an aqueous solution of the active ingredients of opium. It is exceedingly doubtful whether anything is left behind after the opium has been exhausted by water, which materially modifies the action of its anodyne principle; and the extract probably has no advantage on this account over opium. Nor has it the advantage of greater uniformity; as the gum, extractive, &c., taken up by the water, bear no fixed proportion to the active ingredients. But, as purely aqueous preparations of opium have been found to agree better with certain individuals than opium alone or its alcoholic preparations, there is reason to believe that there are in the crude drug one or more principles, capable of causing nausea, headache, nervous disturbance, &c., which are insoluble in water, though extracted by alcohol or ether. M. Guibourt states that this extract, when kept, is apt to swell up, owing, as he at first supposed, to the fermentation of glucose; but he now ascribes the phenomenon to the change of meconic acid into the parameconic, with the escape of carbonic acid. (*Journ. de Pharm.*, Août, 1860, p. 138.)

Denarcotized Extract of Opium. Under the impression that the stimulating and unpleasant effects of opium are owing to the narcotina, it has been proposed to separate that principle by treating the extract with ether, which dissolves the narcotina, and leaves the morphia with the other ingredients. Robiquet employed cold ether; but M. Dublanc, convinced that the whole of the narcotina was not thus extracted, proposed the following plan. "Take of watery extract of opium 16 ounces; dissolve it in 8 ounces of distilled water; introduce the solution into the water-bath of a still; pour upon it 104 ounces of pure ether;

* Professor Procter informs us, as the result of his own observation, that in the alcoholic extract of nux vomica there is a considerable proportion of fixed oil (℥iij in ℥xvi of the seeds), which will not remain mixed with the other ingredients, becoming fluid in summer, and concreting in cold weather. This he thinks should be separated from the extract, and shaken with a little diluted alcohol, which takes from it any adhering active matter. The washings should be evaporated, and the residuum mixed with the extract, the fatty matter being thrown away. (*Note to the tenth edition.*)

distil off 24 ounces of the ether; take apart the apparatus, and decant the ether which floats on the top of the extract; wash the latter while hot with the distilled ether; concentrate the residual matter, dissolve it in distilled water, filter the solution, and evaporate to a proper consistence." It is doubtful whether any useful end is gained by this operation commensurate with its costliness; as there is reason to think that narcotina does not in fact produce the unpleasant effects which have been ascribed to it; and the noxious principles in opium, of which ether is capable of depriving it, are probably left behind, for the most part at least, in the formation of the aqueous extract.

Recluz obtained from sixteen ounces of opium an average product of nine ounces by hot water and six by cold; and Prof. Procter informs us that the U. S. formula usually yields about seven and a half ounces from the same quantity. The dose of the extract of opium is about one-half that of opium itself.

Off. Prep. Emplastrum Opii, *U. S.;* Extractum Opii Liquidum, *Br.;* Trochisci Opii, *Br.;* Vinum Opii, *Br.* W.

EXTRACTUM PAPAVERIS. *Br. Extract of Poppies.*

"Take of Poppy Capsules, dried, freed from the seeds, and coarsely powdered, *one pound* [avoirdupois]; Rectified Spirit *two ounces* [avoird.]; Boiling Distilled Water *a sufficiency.* Mix the Poppy Capsules with two pints [Imperial measure] of the Water, and infuse for twenty-four hours, stirring them frequently; then pack them in a percolator, and, adding more of the Water, allow the liquid slowly to pass until about a gallon [Imp. meas.] has been collected, or the Poppies are exhausted. Evaporate the liquor by a water-bath until it is reduced to a pint [Imp. meas.], and, when cold, add the Spirit. Let the mixture stand for twenty-four hours; then separate the clear liquor by filtration, and evaporate this by a water-bath, until the extract has acquired a suitable consistence for forming pills." *Br.*

The Extract of Poppy Capsules was an officinal of the Lond. and Edin. Colleges, but was abandoned in the formation of the first British Pharmacopœia. It has, however, been introduced into the present edition of that work, though with a process somewhat modified. The London Pharmacopœia merely directed the maceration of the capsules in hot water, boiling down and straining, and then evaporating to a proper consistence. Mr. Brande observed, in relation to the extract thus made, that, if boiled over an open fire, it is often nearly inert. He stated, moreover, that it was apt to have a troublesome consistence, being too hard to be formed into pills, and too tough to be pulverized. It was, we presume, in reference to these objections that the present modifications of the old method were adopted. Decoction has been superseded by maceration and percolation, and evaporation by the water-bath is directed in order to avoid an excessive heat. The addition of the spirit is probably intended to produce coagulation of the albumen, which was effected by heat in the former process. The present formula is no doubt a great improvement upon that of the colleges.

According to Brande, one cwt of the capsules without the seeds yields the average product of 35 pounds of extract. Mr. Jos. Ince, in reference to the London process, recommends that the strained hot decoction, after having been brought by evaporation to a syrupy consistence, should be diluted with eight times its bulk of water, then filtered, and ultimately evaporated. In this way substances which had become insoluble in the evaporation were separated. Thus made, the extract will keep well. (*Pharm. Journ.*, xiv. 489.) M. Meurein gives particular directions for making an alcoholic extract of poppy capsules, which may be consulted with advantage by those who may be called on to supply any demand for this preparation. (See *Journ. de Pharm.*, 3e sér., xxiii. 341.) We are told that an extract is prepared in this country from the whole herb, cut after the fruit has formed, but while it is still green. The capsules exclusively should be used; and the best time for collecting them is immediately after they have begun to become yellowish. The extract possesses the virtues of opium, but is greatly inferior, and less uniform in strength. The dose is from five to ten grains. W.

EXTRACTUM PAREIRÆ. *Br.* *Extract of Pareira.*

"Take of Pareira Root, in coarse powder, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure], or *a sufficiency*. Digest the Pareira with a pint [Imp meas.] of the Water for twenty-four hours; then pack in a percolator, and, adding more of the Water, allow the liquor slowly to pass until a gallon [Imp. meas.] has been collected, or the Pareira is exhausted. Evaporate the liquor by a water-bath until the extract has acquired a suitable consistence for forming pills." *Br.*

Like the preceding extract, this was formerly directed by the London and Edinburgh Colleges, was omitted in the first British Pharmacopœia, and has been adopted again in the present edition. By the formula of the London College, it was prepared by boiling the root in water, straining while hot, and then evaporating to dryness. The British Pharmacopœia more wisely exhausts the root by percolation, and evaporates by a water-bath, thus avoiding the bad effects of long-continued heat. The dose is from ten to thirty grains. W.

EXTRACTUM PHYSOSTIGMATIS. *Br.* *Extract of Calabar Bean.*

"Take of Calabar Bean, in coarse powder, *one pound* [avoirdupois]; Rectified Spirit *four pints* [Imperial measure]. Macerate the Bean for forty-eight hours with one pint [Imp. meas.] of the Spirit in a close vessel, agitating occasionally, then transfer to a percolator, and, when the fluid ceases to pass, add the remainder of the Spirit so that it may slowly percolate through the powder. Subject the residue of the Bean to pressure, adding the pressed liquor to the product of the percolation; filter, distil off most of the Spirit, and evaporate what is left in the retort by a water-bath to the consistence of a soft extract." *Br.*

As alcohol is a much better solvent than water of the active principles of the bean, it is preferred in making the extract. For the uses of the extract, see *Physostigmatis Faba* in *Part* I (page 672). The dose for internal use is from one-sixteenth to one-fourth of a grain. W.

EXTRACTUM PODOPHYLLI. *U. S.* *Extract of May-apple.*

"Take of May-apple, in moderately fine powder, *twelve troyounces;* Alcohol *four pints;* Water *a sufficient quantity.* Introduce the powder, previously mixed with three fluidounces of Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the tincture ceases to pass, pour gradually upon the powder sufficient Water to keep its surface covered, until four pints of tincture have passed. Set this aside, and continue the percolation until six pints of infusion have been obtained. Distil off the alcohol from the tincture, and evaporate the infusion, until the liquids respectively have been brought to the consistence of thin honey; then mix them, and evaporate to the proper consistence." *U. S.*

This is possessed of the purgative properties of the root, and may be given in the dose of from five to fifteen grains. It might be substituted in all cases for the extract of jalap.

From experiments made by Mr. John R. Lewis, it is probable that the alcoholic extract would be much more powerful as a purgative than the officinal preparation; but it does not follow that it would be more serviceable. (See *Am. Journ. of Pharm.*, xix. 170.) W.

EXTRACTUM QUASSIÆ. *U. S., Br.* *Extract of Quassia.*

"Take of Quassia, in moderately fine powder, *twelve troyounces:* Water *a sufficient quantity.* Moisten the Quassia with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the properties of the Quassia. Boil down the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence" *U. S.*

"Take of Quassia Wood, rasped, *one pound* [avoirdupois]; Distilled Water

a sufficiency. Macerate the Quassia with eight fluidounces of the Water for twelve hours; then pack in a percolator, and adding more of the Water allow the liquor slowly to pass until the Quassia is exhausted. Evaporate the liquor; filter before it becomes too thick; and again evaporate by a water-bath until the extract is of a suitable consistence for forming pills." *Br.*

According to M. Recluz, sixteen ounces of Quassia yield by infusion in water seven drachms of extract; by maceration in alcohol of 19° Baumé, two ounces five drachms and a half. The difference between these quantities is so great that we suspect some mistake in the table of the Dictionnaire des Drogues from which we quote.

The extract of quassia is dark-brown or black, and excessively bitter. It is apt to become dry and disposed to crumble by time. It concentrates a greater amount of tonic power within a given weight than any other extract of the simple bitters; and may, therefore, be given with great advantage in cases in which it is desirable to administer this class of substances in as small a bulk, and with as little inconvenience to the patient as possible. The dose is about five grains, to be given in the form of pill. W.

EXTRACTUM RHEI ALCOHOLICUM. *U. S.* EXTRACTUM RHEI. *Br., U. S.* 1850. *Alcoholic Extract of Rhubarb. Extract of Rhubarb.*

"Take of Rhubarb, in moderately fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of the Alcohol, pack it in a conical percolator, and gradually pour upon it, first the remainder of the Alcohol, and afterwards Diluted Alcohol, until twelve fluidounces of tincture have been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to six fluidounces. Continue the percolation with Diluted Alcohol until the tincture passes nearly tasteless. Evaporate this in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. With this mix the tincture first obtained, and continue the evaporation until the mixture is reduced to the proper consistence." *U. S.*

"Take of Rhubarb Root, sliced or bruised, *one pound* [avoirdupois]; Rectified Spirit *ten fluidounces* [Imperial measure]; Distilled Water *five pints* [Imp. meas.]. Mix the Spirit and the Water, and macerate the Rhubarb in the mixture for four days; then decant, press, and set by that the undissolved matter may subside; pour off the clear liquor, filter the remainder, mix the liquors, and evaporate by a water-bath, at a temperature not exceeding 160°, until the extract has acquired a suitable consistence for forming pills." *Br.*

Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation is performed with great care and with a moderate heat, it is certain that the purgative principle is, to a greater or less extent, injured or dissipated in the process; and the extract may thus become even less efficient than the root. Among other consequences which result from the boiling temperature, is the formation of a compound of the tannin and starch, which is insoluble in cold water, and upon its precipitation probably carries with it a portion of the purgative principle. There is, moreover, reason to believe that this principle is volatilizable by heat, and that a portion of it escapes with the vapour. When properly prepared, the extract has decidedly the peculiar odour of rhubarb. The dose of the extract is from ten to thirty grains. W.

EXTRACTUM SENEGÆ ALCOHOLICUM. *U. S.* *Alcoholic Extract of Seneka.*

"Take of Seneka, in moderately fine powder, *twelve troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of Diluted Alcohol, pack it in a conical percolator, and gradually pour upon it Diluted Alcohol until three pints of tincture have passed. Evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

This is a good preparation of Seneka, possessing all its virtues in a concentrated form. There seems to have been no necessity for burdening the title

with the epithet "alcoholicum;" as there is no other officinal extract. For its uses, see *Senega* in *Part* I. The dose is from one to three grains. W.

EXTRACTUM STRAMONII. *U.S.* Extractum Stramonii Foliorum. *U. S* 1850. *Extract of Stramonium. Extract of Stramonium Leaves.*

"Take of Stramonium Leaf *twelve troyounces.* Bruise it in a stone mortar, sprinkling on it a little water, and express the juice; then, having heated this to the boiling point, strain, and evaporate, at a temperature not exceeding 160°, to the proper consistence." *U. S.*

Like all the other inspissated narcotic juices, this is an uncertain preparation, varying in strength according to the care used in conducting the process, and the season at which the leaves are collected. The reader will find at *page* 1128, and in the preliminary observations on the Extracts, some general rules which will prove useful in conducting this process. The insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, may be advantageously rejected; as, according to the observations of MM. Solon and Soubeiran, they are nearly or quite inert. This is done in the present process, which, as well in this respect as in directing the temperature not to exceed 160°, is an improvement of the old one. M. Recluz obtained half an ounce of extract from sixteen ounces of the leaves. The dose is a grain night and morning, to be gradually increased till it affects the system.

Off. Prep. Unguentum Stramonii, *U. S.* W.

EXTRACTUM STRAMONII. *Br.* Extractum Stramonii Seminis. *U.S.* 1850. *Extract of Stramonium. Extract of Stramonium Seed.*

"Take of Stramonium Seeds, in coarse powder, *one pound* [avoirdupois]; Ether *one pint* [Imperial measure], or *a sufficiency;* Distilled Water, Proof Spirit, of each, *a sufficiency.* Shake the Ether in a bottle with half a pint of the Water, and after separation decant the Ether. Pack the Stramonium in a percolator, and free it from its oil by passing the washed Ether slowly through it. Having removed and rejected the ethereal solution, pour the Spirit over the residue of the Stramonium in the percolator and allow it to pass through slowly until the powder is exhausted. Distil off most of the Spirit from the tincture, and evaporate the residue by a water-bath until the extract has acquired a suitable consistence for forming pills." *Br.*

Though with the same name, this is a very different preparation from the preceding one of the U. S. Pharmacopœia, which is the inspissated juice of the leaves; while the British is an alcoholic extract of the seeds. The latter was formerly officinal with us under the name of *Extractum Stramonii Seminis,* while that now named Extractum Stramonii in the U. S. Pharmacopœia was then denominated *Extractum Stramonii Foliorum.* Two things are to be regretted in the changes, in reference to the extracts of stramonium, made in the revision of the Pharmacopœia of 1850; first, that the extract of the seeds, which is perhaps the most efficient preparation of stramonium, should have been abandoned, and, secondly, that the old name of Extractum Stramonii Foliorum should not have been retained; for as the nomenclature now stands, there must be inevitable confusion, only to be guarded against by great care.

This is an excellent preparation, not only stronger, but more uniform, and therefore more to be relied on than any other officinal extract of stramonium. As the seeds yield their virtues more freely to spirit than to water alone, the Br. Pharmacopœia has very properly adopted proof spirit as the menstruum. The use of the ether is to separate inert fatty matter, and consequently to make the extract stronger than when prepared according to the Br. process of 1864, in which ether was not used; and the ether is washed, in order to separate any alcohol contained in it, which might dissolve the active matter. According to the table of Recluz, sixteen ounces of the seed afford two ounces and two drachms of extract by maceration in diluted alcohol, and one ounce and a half by decoction. The dose to begin with is the quarter or half of a grain, twice a day, to be gradually increased. W.

EXTRACTUM STRAMONII ALCOHOLICUM. *U. S. Alcoholic Extract of Stramonium.*

"Take of Stramonium Leaf, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. With this mix the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the mixture is reduced to the proper consistence." *U. S.*

There is no such superiority in this preparation over the inspissated juice as to have called for a separate process; especially as the stramonium plant is so abundant that there can be nowhere any difficulty in obtaining the leaves fresh at the proper season. It is, we think, a poor substitute for the abandoned extract of the seeds. The dose is a grain. W.

EXTRACTUM TARAXACI. *U.S., Br. Extract of Dandelion.*

"Take of Dandelion, gathered in September, *sixty troyounces.* Slice the Dandelion, and bruise it in a stone mortar, sprinkling on it a little water, until reduced to a pulp. Then express and strain the juice, and evaporate it in a vacuum, or in a shallow dish over a water-bath, to the proper consistence." *U. S.*

"Take of Fresh Dandelion Root *four pounds* [avoirdupois]. Crush the Root; press out the juice, and allow it to deposit; heat the clear liquor to 212°, and maintain the temperature for ten minutes; then strain, and evaporate by a water-bath, at a temperature not exceeding 160°, until the extract has acquired a suitable consistence for forming pills." *Br.*

This extract is undoubtedly stronger, prepared from the root alone than from the whole plant. It is important that the root should be collected at the right season. The juice expressed from it in the spring is thin, watery, and of a feeble flavour; in the latter part of the summer, and in autumn, thick, opaque, cream-coloured, very bitter, and abundant, amounting to one-third or one-half its weight. It may be collected in August, and afterwards until severe frost. According to Mr. Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the root. An extract prepared by inspissating the juice, as in the present U. S. and Br. processes, is much more efficient than that prepared in the old way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure, during evaporation, changes the bitterness of the juice into sweetness, which is a sign of inferiority. In the British process, it is wisely directed that, before the evaporation of the juice, it shall be exposed for a short time to a heat sufficient to coagulate the albumen, which is then separated and rejected as useless, and indeed injurious by favouring decomposition. As often found in the shops, the extract is dark-coloured, sweet, and in all probability nearly inert. Mr. Houlton took more than an ounce of it in a day, without any sensible effect. (*Pharm Journ.*, i. 421.) When prepared from the root and leaves together, it has a greenish colour. Mr. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained in November, and the least in April and May.

This extract deteriorates by keeping, and should, therefore, be renewed annually. It is most conveniently given dissolved in cinnamon or mint water. The dose is from a scruple to a drachm three times a day. W.

EXTRACTUM VALERIANÆ ALCOHOLICUM. *U. S.* *Alcoholic Extract of Valerian.*

"Take of Valerian, in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of Alcohol, pack it in a percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, and evaporate this, by means of a water-bath, to the consistence of syrup. Lastly, mix the two liquids, and continue the evaporation, at a temperature not exceeding 120°, until the mixture is reduced to the proper consistence." *U. S.*

This extract contains most of the active matter of the root, though a portion of the volatile oil may be lost in the process. It may be used for obtaining the effects of valerian on the system. According to Vielguth and Nentwich, the root yields 23 per cent. of its weight to cold diluted alcohol by percolation The dose of the extract is from ten to thirty grains. W.

EXTRACTA FLUIDA.

Fluid Extracts.

These were first introduced into the U. S. Pharmacopœia of 1850, as a distinct class of preparations; the fluid extract of sarsaparilla being the only one previously directed, either in our own officinal code, or by the British Colleges. Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form. Independently of the greater convenience of administration, the advantage of this class of preparations is that, the evaporation not being carried so far as in the ordinary extracts, the active principles are less liable to be injured by heat. The main difficulty, in relation to them, is the liability of substances in the liquid state to undergo spontaneous decomposition. This is counteracted in some of the fluid extracts by means of sugar, in others by alcohol, and in others, again, by a mixture of the two. Formerly a class of preparations was united with the fluid extracts, which in the present edition of the Pharmacopœia hold a distinct position, under the name of *oleoresins.* In these the extracted matter is in its own nature preservative; but they will be considered elsewhere. In a few of the fluid extracts in which acetic acid is used as one of the menstrua, this also probably contributes to their preservation. In all of them alcohol or alcohol and water are employed as the menstruum, one being preferred to the other according to the character of the active principle or principles to be extracted. In all, moreover, the extraction is effected by percolation; and in the evaporation great care is taken not to injure the product by too great a heat. Though the greater portion of the alcohol is evaporated, a part generally remains, which contributes towards the preservation of the preparation; but, as this alone is often insufficient, it is necessary to have recourse to sugar, which has the subsidiary advantage of improving the flavour. In the fluid extracts, however, instead of two pounds of sugar to each pint of the liquid, as in the case of the ordinary syrups, it is generally sufficient to add an ounce for every fluidounce. Instead of sugar, Mr. Alfred B. Taylor has proposed the use of glycerin, which, while it has the same preservative influence, possesses besides the valuable property of dissolving matters which are deposited by some of the fluid extracts in which sugar is employed, rendering them turbid, and giving them a repulsive aspect. He has tried the glycerin in one or more of the fluid extracts liable to this disadvantage, and found it to answer perfectly. (*Am. Journ. of Pharm.*, Jan. 1865, p. 50.) The British Pharmacopœia has a few of these preparations, which it prefers to name *Extracta Liquida.*

For valuable remarks upon the Fluid Extracts, and many important practical rules in the preparation of the several articles of the class, the reader is referred to reports by Prof. Procter in the *Proceedings of the American Pharmaceutical Association* for 18[illegible] (p. 265), and for 1863 (p. 222). We would strongly impress on practical pharmaceutists the great importance of fulfilling carefully every officinal direction in the several formulas which follow, and especially of conducting most cautiously the process of percolation, upon the due performance of which the efficiency of the product so much depends. Properly prepared, the fluid extracts are among the most efficacious, convenient, and elegant medicinal preparations; whereas, if carelessly or ignorantly made, there are probably none which would be more likely to deceive the hopes of the practitioner.

The high price of alcohol of late has tended greatly to increase the cost, and consequently to limit the use, of the fluid extracts; and it is asserted that in regard to those prepared, a regard to economy has, in many instances, caused deviations from the officinal formulas which have led to variable and uncertain results. It will certainly be very desirable, when another revision of the Pharmacopœia is made, to take all the proposed changes into consideration, and make such modifications of the officinal processes as may be deemed desirable, whether in regard to economy or efficiency. In the mean time, however, the officinal directions should be adhered to, whenever practicable, in reference to all preparations having special officinal names; or, if they are departed from, the fact should be indicated in the title of the preparation.

Two modes have been suggested of preparing the fluid extracts more economically; one, by applying the plan of repercolation, as proposed by Dr. E. R. Squibb, to this class of preparations as well as to the dry extracts; the other by means of expression, as recommended by Mr. N. Spencer Thomas. With the peculiarities of the former method the reader is already familiar. Much may be said in its favour; but it is liable to two objections; one, that, by leaving the medicine incompletely exhausted, it endangers results more or less different from those officinally contemplated; the other, that, in order to obviate this inconvenience, a degree of knowledge and skill is requisite not always met with in those whose business it is to make these preparations. As regards the plan of Mr. Thomas, it consists in exposing the substance to be acted on to successive expressions, by means of a press, with the menstruum divided into different portions; so that fresh portions of liquid are brought to act on the same solid body in different stages of exhaustion; and then mixing the expressed liquids. The due proportion between the weight of the medicine and the bulk of the ultimate fluid extract is secured by regulating the measure of the last-added portion of menstruum, which, in the process as described by Mr. Thomas, is the third. Whatever may be the advantages of this method, and it is not without its recommendations, it is liable to the objection of having been patented. (*Am. Journ. of Pharm.*, May, 1866, p. 219.)

A third method of limiting the quantity of alcohol used, has been very recently proposed by Mr. S. P. Duffield of Detroit. It consists in macerating, for from six to ten days, the medicine to be acted on, previously deprived, by means of a vacuum apparatus, of all the air, and of all readily volatilizable matter contained in its pores, with a certain volume of the menstruum, which is forced through a tube into the vacuum pan by atmospheric pressure, and thus brought into the most intimate contact with all parts of the powder. The process is completed by submitting the mass thus impregnated to hydraulic pressure, and, after allowing the liquid to settle in glass carboys, drawing off the clear liquid into bottles. It is only by experience that the value of this process can be determined. (*Ibid.*, Jan. 1869, p. 2.) It is obviously inapplicable to substances, whose virtues depend in any considerable degree upon readily volatilizable constituents. W.

EXTRACTUM BELÆ LIQUIDUM. *Br. Liquid Extract of Bael.*

"Take of Bael Fruit *one pound* [avoirdupois]; Distilled Water *twelve pints*

[Imperial measure]; Rectified Spirit *two fluidounces.* Macerate the Bael for twelve hours in one-third of the Water; pour off the clear liquor; repeat the maceration a second and third time for one hour in the remaining two thirds of the Water; press the marc; and filter the mixed liquors through flannel. Evaporate to fourteen fluidounces; and, when cold, add the Rectified Spirit." *Br.*

This is a new officinal of the British Pharmacopœia, of which very little is known in the United States. It is one of the forms in which the new India remedy bael is employed, and the reader is referred to the article on that subject in *Part* I. Each fluidounce of the extract represents an avoirdupois ounce of the medicine, and the dose is from one to four fluidrachms. W.

EXTRACTUM BUCHU FLUIDUM. *U. S. Fluid Extract of Buchu.*

"Take of Buchu, in moderately fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the Buchu with six fluidounces of Alcohol, introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, and mix it with the reserved tincture. Allow the mixture to stand for twenty-four hours, and filter through paper." *U. S.*

In consequence of the tenacity of the leaves, it is somewhat difficult to powder them in a mortar, and it will be convenient to resort to a mill for the purpose. As the most active ingredient of buchu is volatile, the direction in the formula to set aside the first portion of tincture obtained, which is a highly concentrated solution, is peculiarly important; for, if it were subjected to evaporation, much of the volatile oil would necessarily escape. The facility of obtaining such concentrated solutions by means of percolation is one of the greatest recommendations of the process, and is especially valuable in the preparation of the fluid extracts. The tincture subsequently obtained probably contains a large proportion of the fixed ingredients of the leaves, and will, therefore, allow of concentration without material loss. This is one of the fluid extracts in which alcohol acts at once as the menstruum and the preservative agent. The preparation is, indeed, nothing more than a very concentrated tincture; and, as buchu is itself a stimulant agent, and generally exhibited in cases admitting or requiring stimulation, there is no medicinal incompatibility in the case.

In a criticism upon this article, contained in the *Proceedings of the Amer. Pharm. Association* of 1866, Dr. E. R. Squibb offers two amendments; one in reference to the fineness of the powder, which he thinks cannot be too fine; the other as to the quantity of alcohol used in percolation, which, in view of the costliness of that fluid, might with propriety be greatly reduced. For successful percolation it is necessary that the process should be slowly performed; and, in the commencement, the filtrate should not be allowed to pass more rapidly than at the rate of one drop in a second. This slowness of percolation cannot be commanded if the powder is coarse; hence his recommendation upon this point. The quantity of alcohol used for obtaining the second portion of percolate might, as he believes, be reduced one-half without perceptibly impairing the virtues of the fluid extract; the last pint that passes extracting comparatively very little from the powder. Dr. Squibb offers a process in conformity with these views, and with his plan of percolation, which may be seen in the *Am. Journ. of Pharm.* (March, 1867, p. 133).

This fluid extract is clear, at first greenish, but at length of a dark reddish-brown colour, and possessed in a high degree of the sensible properties of the leaves. It is said to acquire the odour of mint when long kept, showing that some change takes place in its volatile oil. Each fluidounce of the fluid extract represents a troyounce of the leaves; and the dose is twenty or thirty minims, to be given diluted with water. W

EXTRACTUM CIMICIFUGÆ FLUIDUM. *U. S. Fluid Extract of Cimicifuga.*

"Take of Cimicifuga, in fine powder, *sixteen troyounces;* Stronger Alcohol

a pint and a half; Diluted Alcohol *a sufficient quantity.* Moisten the Cimicifuga with four fluidounces of the Stronger Alcohol, introduce it into a conical percolator, pour upon it the remainder of the Stronger Alcohol, and, when the whole of this has entered the powder, gradually add Diluted Alcohol until a pint and a half of tincture have passed. Set this aside, in a shallow vessel, in a warm place, until reduced by spontaneous evaporation to twelve fluidounces. Continue the percolation with Diluted Alcohol, until two pints more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces; then add the tincture first obtained very gradually so as to avoid precipitation, allow the mixture to stand for twenty-four hours, and filter through paper." *U. S.*

This is essentially the process of Prof. Procter, published in the eleventh edition of the U. S. Dispensatory (*page* 226); stronger alcohol being substituted as the first menstruum for a mixture of alcohol and ether. There can be little doubt, we think, that cimicifuga depends, for its remedial effects, in part upon a volatile principle. Hence the necessity for submitting the pint and a half of concentrated tincture first obtained to spontaneous evaporation, without the aid of the water-bath subsequently employed. As cimicifuga is often given in cases requiring rather a sedative than a stimulant influence, it is desirable to have no more alcohol in the preparation than may be necessary for its preservation. On this account, the first tincture with alcohol is allowed to diminish one-half by spontaneous evaporation; and the process is completed with diluted alcohol, which loses nearly all its spirit in the subsequent concentration. As the result, in the latter case, is little more than a strong aqueous solution, there is some precipitation of resin when the first alcoholic solution is added to it, unless care is taken to make the mixture very gradually. This fluid extract is of a very dense reddish-brown colour, and clear, yet disposed to deposit a resinoid sediment on standing. It is probably one of the fluid extracts in which glycerin might be advantageously employed. It has the peculiar odour and taste of cimicifuga. A fluidounce of it represents a troyounce of the root, and probably contains all or nearly all its virtues. The dose is from thirty minims to a fluidrachm. W.

EXTRACTUM CINCHONÆ FLUIDUM. *U. S.* EXTRACTUM CINCHONÆ FLAVÆ LIQUIDUM. *Br. Fluid Extract of Cinchona. Liquid Extract of Yellow Cinchona.*

"Take of Yellow Cinchona, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *twenty troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Cinchona with ten fluidounces of Diluted Alcohol, allow it to stand for half an hour, pack it firmly in a cylindrical percolator, and gradually pour upon it Diluted Alcohol until four pints of tincture have been obtained. Evaporate this, by means of a water-bath, to two pints; then add the Sugar, evaporate again to two pints, and strain the liquid while hot." *U. S.*

"Take of Yellow-Cinchona Bark, in coarse powder, *one pound* [avoirdupois]; Distilled Water *a sufficiency;* Rectified Spirit *one fluidounce.* Macerate the Cinchona Bark in two pints [Imp. meas.] of the Water for twenty-four hours, stirring frequently; then pack in a percolator, and add more Water, until twelve pints [Imp. meas.] have been collected, or until the Water ceases to dissolve anything more. Evaporate the liquor at a temperature not exceeding 160° to a pint [Imp. meas.]; then filter through paper, and continue the evaporation to three fluidounces, or until the sp. gr. of the liquid is 1·200. When cold, add the Spirit gradually, constantly stirring. The sp. gr. should be about 1·100." *Br.*

Of these two formulas, the first is decidedly preferable. It is essentially that of Mr. Alfred B. Taylor, of Philadelphia, and was described in the eleventh edition of this work (*page* 272). The British Pharmacopœia uses water only as the menstruum, while it adds alcohol to the liquid to preserve it. In the U. S. process diluted alcohol is used as the menstruum, and the alcohol afterwards almost all driven off, sugar being used as the preservative agent. Now it is well known that Peruvian bark cannot be exhausted by water alone; and, though by

its use as a menstruum the resin and cinchonic red are mainly left behind, so also is a considerable proportion of the alkaloids. By using diluted alcohol the U. S. Pharmacopœia extracts all the virtues of the bark, and, though it may also take up some of the resin and cinchonic red, it avoids any gummy matter that may be present, and gets rid of most of the other inert matters during the evaporation. The British preparation contains one-fourth of alcohol, and is in fact a tincture; the U. S. fluid extract is a highly concentrated infusion preserved by sugar. Of the former, four fluidounces are intended to represent an avoirdupois pound or sixteen ounces of the bark; but certainly fail to do so, and to an indefinite degree. Of the latter, two fluidounces actually represent an ounce of the bark, and may be relied on, if well prepared, to produce all its effects. The direction, in the U. S. process, to strain while hot is necessary; because a portion of the cinchonic red and cinchotannates of the alkaloids, which are much more soluble in the hot than in the cold liquid, is deposited when it cools. The U. S. fluid extract is consequently somewhat turbid, at least deposits a sediment on standing, and should be shaken when administered. When shaken, it is opaque, and of a light brownish-red colour, as if prepared rather from red than Calisaya bark.

Mr. Taylor, since his original suggestion of the present U. S. formula, has found that the insoluble matter which renders the fluid extract turbid may be dissolved by a certain proportion of glycerin with the aid of heat. A portion of the turbid fluid extract mixed with an equal bulk of glycerin, and exposed to heat, became perfectly clear, and remained so after cooling. Influenced by this result, he prepared a formula in which glycerin was substituted for sugar in making the fluid extract, in the proportion of 8 fluidounces for 16 troyounces, with the effect of producing a perfectly clear preparation, possessing all the remedial properties of cinchona, not liable to change by fermentation, and having the same strength as the officinal fluid extract. For the precise formula used by Mr. Taylor, see the *Am. Journ. of Pharm.* for Jan. 1865 (p. 51).

The dose equivalent to a drachm of the bark is two fluidrachms; and to produce an antiperiodic effect, at least two fluidounces should be taken between the paroxysms. W.

EXTRACTUM COLCHICI RADICIS FLUIDUM. *U. S.* *Fluid Extract of Colchicum Root.*

"Take of Colchicum Root, in fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water, moisten the Colchicum Root with six fluidounces of the mixture, press it moderately in a conical percolator, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

EXTRACTUM COLCHICI SEMINIS FLUIDUM. *U. S.* *Fluid Extract of Colchicum Seed.*

"Take of Colchicum Seed, in moderately fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water, moisten the Colchicum Seed with six fluidounces of the mixture, press it firmly in a conical percolator, and pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

These two preparations, the one of the cormus, the other of the seeds of Colchicum, are made precisely in the same manner, and are nothing more nor less than strong tinctures. Considering that we had one tincture, two wines, and two extracts of Colchicum, all efficient preparations, these additions to our pharmacy might have been spared, unless some peculiar advantage could have been gained from them. They are, however, well made, and no doubt concentrate the virtues of colchicum within a small space. The proportion of two measures of alcohol

to one of water was preferred to that of equal measures, as in diluted alcohol, because the latter was found to extract an inert matter from the material operated on, which is left behind by the former. The process is one of those published by Prof. Procter in the *Proceedings of the American Pharmaceutical Association* for 1859 (p. 264).

The fluid extracts of colchicum are of a deep-brown colour, and somewhat turbid. In relation to that from the seeds, Mr. Maisch states that it cannot be obtained clear by filtration through either a dry or moist filter; but, on being allowed to stand for some days, it separates into two layers, the upper greenish-brown and of an oily nature, on the removal of which the lower layer is left permanently clear. (*Am. Journ. of Pharm.*, March, 1864, p. 97.) It is probable that the use of glycerin in the preparation would obviate this inconvenience. Supposing the root and seeds to be exhausted by the menstruum employed, and none of the active matter to be lost in the evaporation, a troyounce of each is represented by a fluidounce of the fluid extract, the dose of which, therefore, would be from two to eight minims. W.

EXTRACTUM CONII FLUIDUM. *U. S. Fluid Extract of Hemlock.*

"Take of Hemlock, recently dried and in fine powder, *sixteen troyounces;* Acetic Acid *half a fluidounce;* Diluted Alcohol *a sufficient quantity.* Mix the Acid with three pints of Diluted Alcohol, moisten the powder with half a pint of the mixture, pack it in a conical glass percolator, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation, first with the remainder of the mixture, and afterwards with Diluted Alcohol, until three pints more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

This process has the same origin as the preceding. It is scarcely possible that a liquid preparation of hemlock could be made, in which the virtues of the drug should be more satisfactorily concentrated. By the use of acetic acid we probably increase the solvent powers of the menstruum, contribute to protect the alkaloid against decomposition during the concentration, and aid the alcohol in preserving the fluid extract when completed. Prof. Procter states that the tendency of the alkaloid to decomposition is entirely controlled by acetic acid at any temperature below 150° F. (*Proceedings of the Am. Pharm. Assoc.*, 1859, p. 272.) From the great facility with which conia is destroyed by heat, it is an important provision in the process, to make first as highly concentrated a tincture as possible, containing most of the virtues of the leaves, to be reserved for admixture with the portion which has undergone evaporation. But the fluid extract must partake of the uncertainty of the leaves themselves, and hence the importance of using them immediately after they are dried, and of taking care that they should be properly dried. It is a thick but mobile, very dark liquid, with a yellowish tint in thin layers, and having in a decided degree the peculiar odour of the leaves. When treated with an alkali, it should give out strongly the mouse-like odour of the alkaloid conia; but too frequently this essential characteristic is wanting, either from defect in the leaves used, or some error in performing the process. In a specimen which came under our notice, having all the other qualities of the fluid extract in perfection, this mouse-like odour, on contact with potassa, was entirely wanting. One fluidounce contains the active matter of a troyounce of the leaves; and four or five minims may be given as a commencing dose, to be somewhat rapidly increased until its effects are felt. W.

EXTRACTUM DULCAMARÆ FLUIDUM. *U.S. Fluid Extract of Bittersweet.*

"Take of Bittersweet, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *ten troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Bittersweet with half a pint of Diluted Alcohol, pack it in a coni-

cal percolator, and pour upon it Diluted Alcohol until three pints of tincture have passed. Evaporate this, by means of a water-bath, to a pint, add the Sugar, evaporate again to a pint, and strain the liquid while hot." *U. S.*

In this fluid extract, as, in view of the sedative properties of the medicine, is obviously indicated, the alcohol employed in extracting the virtues of the twigs is almost entirely evaporated, and sugar is depended on for the prevention of spontaneous change. By straining while hot, the active matter deposited on cooling is detained in the preparation, which is therefore somewhat turbid, and should be shaken when administered. This is one of the fluid extracts in which, according to the views of Mr. Taylor, glycerin might be substituted for sugar, with probable advantage in securing a clear preparation. (See *page* 1155.) It is a thickish, almost syrupy liquid, of a dark-olive hue, with the sensible properties of the bittersweet in a concentrated state. One fluidounce represents a troyounce of the twigs. The dose is from thirty minims to a fluidrachm, three or four times a day, and gradually increased if necessary. W

EXTRACTUM ERGOTÆ FLUIDUM. *U. S.* EXTRACTUM ERGOTÆ LIQUIDUM. *Br.* *Fluid Extract of Ergot.* *Liquid Extract of Ergot.*

"Take of Ergot, in fine powder, *sixteen troyounces;* Acetic Acid *half a fluidounce;* Diluted Alcohol *a sufficient quantity.* Mix the Acid with three pints of Diluted Alcohol, and, having moistened the Ergot with four fluidounces of the mixture, introduce it into a conical glass percolator, pressing moderately, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation, first with the remainder of the mixture, and afterwards with Diluted Alcohol, until three pints more of tincture have been obtained. Evaporate this by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

"Take of Ergot, in coarse powder, *one pound* [avoirdupois]; Ether *one pint* [Imperial measure], or *a sufficiency;* Distilled Water *three pints and a half* [Imp. meas.]; Rectified Spirit *eight fluidounces.* Shake the Ether in a bottle with half a pint [Imp. meas.] of the Water, and after separation decant the ether. Place the Ergot in a percolator, and free it from its oil by passing the washed ether slowly through it. Remove the marc, and digest it in three pints [Imp. meas.] of the Water at 160° for twelve hours. Press out, strain, and evaporate the liquor, by the heat of a water-bath, to nine fluidounces; when cold, add the Spirit. Allow it to stand for an hour to coagulate, then filter. The product should measure sixteen fluidounces." *Br.*

These are not identical preparations. The U. S. fluid extract is probably the best officinal preparation of ergot, having all the virtues of the medicine in a concentrated state. It was first suggested by Mr. Jos. Laidley, of Richmond, Va.; but the process has since been variously modified by different writers, and in its present state was taken from the Proceedings of the American Pharmaceutical Association before referred to. (See *page* 1156.) Diluted alcohol dissolves all the active matter of ergot, leaving its oil behind, and the tincture first obtained, holding most of the active principles, is reserved without concentration; while the acetic acid has the effect of counteracting the injurious influence of the heat used in concentrating the tincture subsequently passed, probably by forming fixed salts with the alkaloids. In the British process, the first step is to dissolve out the oil with ether previously deprived of alcohol by washing with water; because ordinary ether, in consequence of the alcohol it contains, dissolves a portion of the active matter along with the oil. The remainder of the process consists simply in forming an infusion with the residue of the ergot by digesting it with water, and then adding the spirit to preserve it. Why the ether should be used to dissolve out the oil, it is difficult to understand, when it is considered that, if this menstruum were not employed, the oil would remain undisturbed in the ergot.

The U. S. fluid extract of ergot is a clear, very dark reddish-brown liquid,

having the taste of ergot, but without its fishy odour, owing to the fixation of the alkaloid propylamia, upon which that odour depends. On the addition, however, of solution of potassa, the odour is strongly developed, and the alkaloid escapes so largely that, if muriatic acid be held near it, a cloud of muriate of propylamia will be perceived. This may be considered as a good test of the efficiency of the preparation; for, though all the virtues of ergot do not depend on its volatile alkaloid, yet, if this be retained in the fluid extract, there can be little doubt that the other more fixed principles will be retained also. One fluidounce of the preparation, made by the U. S. process, represents a troyounce of the ergot; according to the British, an avoirdupois ounce. The dose is from ten to twenty minims. W.

EXTRACTUM FILICIS LIQUIDUM. *Br. Liquid Extract of Fern.*

This, being properly an oleoresin, will be considered under the head of the *Oleoresinæ*, to which the reader is referred.

EXTRACTUM GENTIANÆ FLUIDUM. *U. S. Fluid Extract of Gentian.*

"Take of Gentian, in moderately fine powder, *sixteen troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Gentian with six fluidounces of Diluted Alcohol, introduce it into a conical percolator, pressing moderately, and pour upon it Diluted Alcohol until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this, by means of a water-bath, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

This is a concentrated tincture of gentian, transparent, reddish-brown, with the smell and taste of the root, of which a troyounce is represented by a fluidounce of the preparation. It may be questionable whether it was needed, though it has the advantage that we may obtain from it the tonic effects of the drug, with less alcohol than in an equivalent quantity of the tincture; and pharmaceutically it affords a convenient method of giving to mixtures the tonic properties of gentian when required. The dose is from ten to thirty or forty minims. W.

EXTRACTUM HYOSCYAMI FLUIDUM. *U. S. Fluid Extract of Henbane.*

"Take of Henbane Leaf, in fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water, moisten the powder with six fluidounces of the mixture, pack it firmly in a conical percolator, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation with the same mixture until two pints and a half more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

Like the preceding fluid extract, this is a concentrated alcoholic tincture, in which the menstruum, instead of being diluted alcohol, is somewhat stronger, consisting of two measures of alcohol to one of water. It is clear at first, though apt to become somewhat turbid, is of a dark-brown colour, and possessed of the taste and smell of the leaves in a high degree. It was first proposed by Mr. Ch. A. Smith of Cincinnati (*Am. Journ. of Pharm.*, xxv. 410); but the formula is that of Prof. Procter, taken from the *Proceedings of the American Pharmaceutical Association* for 1859. The commencing dose is from five to ten minims. W.

EXTRACTUM IPECACUANHÆ FLUIDUM. *U. S. Fluid Extract of Ipecacuanha.*

"Take of Ipecacuanha, in fine powder, *sixteen troyounces;* Acetic Acid *a fluidounce;* Alcohol, Water, each, *a sufficient quantity.* Moisten the Ipecacuanha with six fluidounces of Alcohol, introduce it into a conical percolator, press it firmly, and pour Alcohol upon it until three pints of tincture have

slowly passed, or until the Ipecacuanha is exhausted. Distil off the alcohol from the tincture, by means of a water-bath, until a syrupy liquid is left. Mix this with the Acetic Acid and ten fluidounces of Water, boil the mixture gently until it is reduced to half a pint, and the resinous matter has separated. Filter the liquid when cold, and add sufficient Water, through the filter, to make the filtered liquid measure half a pint. Lastly, mix this with half a pint of Alcohol." *U. S.*

A strong tincture is first obtained with officinal alcohol, from which the spirit is afterwards distilled off; the object in using this menstruum being to obtain the active principle of the root, without the gum and starch which give to its liquid preparations a tendency to decomposition. To separate the resinous matter water is then added, together with acetic acid to give stability to the alkaloid during the subsequent boiling. When this is accomplished, the liquid is filtered and diluted with water, and sufficient alcohol to preserve it. A formula for this fluid extract was originally proposed by Mr. Laidley, of Richmond, Va., but was afterwards modified. The addition of acetic acid was suggested by Prof. Procter.

The fluid extract is a thin, dark reddish-brown transparent liquid, of a bitterish slightly acrid taste, but without the nauseous flavour of the root. A fluidounce of it represents an ounce of the root, and the emetic dose would therefore be from fifteen to thirty minims. It is a convenient preparation for adding to expectorant and diaphoretic mixtures, and is used officinally in preparing the syrup of ipecacuanha.

Off. Prep. Syrupus Ipecacuanhæ, *U. S.* W.

EXTRACTUM LUPULINÆ FLUIDUM. *U.S.* *Fluid Extract of Lupulin.*

"Take of Lupulin *sixteen troyounces;* Stronger Alcohol *a sufficient quantity.* Introduce the Lupulin into a percolator, press it firmly, and, having covered it with a piece of muslin, pour upon it Stronger Alcohol very gradually until twelve fluidounces of tincture have passed. Set this aside in a close vessel, and continue the percolation until twenty fluidounces more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, and mix it with the reserved tincture." *U. S.*

This is a concentrated tincture of lupulin, containing the virtues of an ounce of lupulin in a fluidounce. The dose is ten or fifteen minims, which may be conveniently given mixed with syrup of gum arabic, afterwards diluted with water. W.

EXTRACTUM OPII LIQUIDUM. *Br.* *Liquid Extract of Opium.*

"Take of Extract of Opium *one ounce* [avoirdupois]; Distilled Water *sixteen fluidounces* [Imperial measure]; Rectified Spirit *four fluidounces* [Imp. meas.]. Macerate the Extract of Opium in the Water for an hour, stirring frequently; then add the Spirit, and filter. The product should measure one pint [Imp. meas.]." *Br.*

This is a good preparation, one which has long been needed, and in the absence of which from the Pharmacopœias empirical preparations have obtained a certain vogue. It is well known that in opium there are principles, soluble in alcohol but not in water, which often produce various disagreeable effects, not experienced from the watery extract. What was wanted was a liquid preparation meeting this demand. All that was required was to make an aqueous solution of the watery extract, and to add something to preserve it. The British Pharmacopœia uses alcohol for the purpose, and in the original formula employed it in such proportion that an Imperial pint of the liquid should contain three fluidounces of the spirit, or between one-sixth and one-seventh by measure. But this amount of alcohol, according to Mr. Squire, is insufficient for its preservation, and should be doubled. In the present Pharmacopœia the spirit has been increased to four fluidounces, and the water diminished from seventeen to sixteen fluidounces; but even with this increase the spirit constitutes

only one-fifth, which is considerably short of the proportion recommended by Mr. Squire. A preparation similar to the British was made some years since by Mr. Eugene Dupuy, of New York, an account of which is given in a note to Opium in *Part* I. of this work (*page* 653). In the new *Deodorized Tincture of Opium* of the U. S. Pharmacopœia, the advantages of the preparation have, we think, been still better secured. (See *Tinctura Opii Deodorata.*) The dose of the liquid extract, equivalent to a grain of opium, would be about 10 minims. W.

EXTRACTUM PAREIRÆ LIQUIDUM. *Br.* *Liquid Extract of Pareira.*

"Take of Pareira Root, in coarse powder, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure], or *a sufficiency;* Rectified Spirit *three fluidounces.* Digest the Pareira with a pint [Imp. meas.] of the Water for twenty-four hours, then pack in a percolator, and, adding more of the Water, allow the liquor slowly to pass until a gallon [Imp. meas.] has been collected, or the Pareira is exhausted. Evaporate the liquor by a water-bath to thirteen fluidounces, and, when it is cold, add the Spirit, and filter through paper." *Br.*

This is a concentrated infusion, preserved by adding somewhat less than one-fourth of its measure of alcohol, and is said by those who have used it to have all the virtues of the root. The fluid extract would probably be still more efficient if made with diluted alcohol. The dose is one or two fluidrachms. W.

EXTRACTUM PRUNI VIRGINIANÆ FLUIDUM. *U. S.* *Fluid Extract of Wild-cherry Bark.*

"Take of Wild-cherry Bark, in fine powder, *sixteen troyounces;* Sweet Almond *two troyounces;* Sugar, in coarse powder, *twenty-four troyounces;* Alcohol, Water, each, *a sufficient quantity.* Introduce the Bark, previously mixed with four fluidounces of Alcohol, into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until three pints of tincture have slowly passed. From this distil off two pints and a half of alcohol, and, having mixed the residue with a pint of Water, evaporate, by means of a water-bath, to half a pint.

"Beat the Almond into a paste, and rub this with successive portions of Water until, after straining through a coarse sieve or cloth, nearly all the substance of the Almond has been converted into an emulsion, and twelve fluidounces of liquid have been obtained. Mix this with the liquid first obtained, in a suitable bottle, and, having closely stopped it, agitate occasionally during twenty-four hours. Then express quickly and strongly through a cloth; and, if the expressed liquid measure less than eighteen fluidounces, add Water to the residue, and again express until that quantity is obtained. Filter the expressed liquid through cotton flannel, in a covered funnel, into a bottle containing the Sugar. Shake the bottle occasionally during the process until the Sugar is dissolved, and continue the filtration until the syrupy liquid measures two pints. Lastly, mix the whole thoroughly together." *U. S.*

This is an ingenious and effectual method of obtaining the virtues of wild-cherry bark in a concentrated liquid form, adopted from a process originally devised and published by Prof. Procter. For various reasons it is expedient to use alcohol as the menstruum for extracting the soluble principles of the bark; the chief reasons being that substances are thus left behind, which if extracted would dispose the preparation to spontaneous change, and that less heat, or a shorter continuance of it, is required in the concentration than if water were the solvent. But by the use of alcohol we prevent those reactions which, by the production of volatile oil and hydrocyanic acid, give the medicine its peculiar value; and the addition of water to the tincture obtained, though in connection with the bark itself it would give rise to the requisite reactions, fails to produce them because the emulsin of the bark, which is essential to the result, is not only not extracted by the alcohol, but is rendered inert by it. It is through the agency of this principle

that the amygdalin of the bark reacts with water so as to generate volatile oil and hydrocyanic acid. The alcohol extracts the amygdalin but not the emulsin, nor can the latter principle be now procured from the bark, because it has been destroyed by the alcohol. If, therefore, we wish to obtain the characteristic remedial principles of the bark, such as they exist in the infusion, we must seek for emulsin from another source; and the most convenient is sweet almond. Hence the direction to obtain an emulsion from almonds, which contain emulsin largely. But, if added to the alcoholic liquid first obtained, it would be wholly inoperative, and indeed would be rendered inert for future action. It is, therefore, necessary to separate all the alcohol from that liquid, and replace it with enough water to hold the amygdalin in solution. This is done by first distilling off two and a half of the three pints of alcohol, then adding water, and lastly evaporating all the remainder. This is an essential step of the operation, and success need not be expected unless the alcohol is got rid of. We now have an aqueous solution of amygdalin and whatever other bitter principles the bark may contain; and, when the almond emulsion is added, all the conditions exist requisite to the generation of the oil of bitter almonds with hydrocyanic acid. Nothing now remains but to allow full time for the requisite reaction, then to strain the liquid, adjust the proportion of water necessary to give the desired measure of fluid extract, and add enough sugar to preserve it. Heat is contraindicated in the latter part of the process, as it must interfere with the action of the emulsin, and would certainly drive off a portion of the active volatile principles. Hence, all the requisite concentration must be effected before the almond emulsion is added. If properly made, the fluid extract is a clear syrupy liquid, of a light sherry-wine colour, having strongly the peculiar bitter taste and hydrocyanic acid flavour of the infusion, and capable of dilution to any extent with water, without becoming turbid. As two pints of fluid extract are produced, and the quantity of bark used is sixteen troyounces, it follows that an ounce of the bark is represented by two fluidounces of the fluid extract, the dose of which, therefore, is from one to two fluidrachms. W.

EXTRACTUM RHEI FLUIDUM. *U. S.* *Fluid Extract of Rhubarb.*

"Take of Rhubarb, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Moisten the Rhubarb with four fluidounces of the Alcohol, introduce it into a conical percolator, press it gently, and pour upon it the remainder of the Alcohol. When the liquid has disappeared from the surface, gradually pour on Diluted Alcohol until a pint of tincture has passed. Set this aside in a warm place until reduced by spontaneous evaporation to six fluidounces, and continue the percolation until two pints more of tincture have been obtained. Evaporate this by a gentle heat to six fluidounces; then add the Sugar, and, when this is dissolved, the reserved tincture, and continue the heat until the whole is reduced to the measure of a pint." *U. S.*

The fluid extract of 1850 contained the aromatic oils of fennel and anise, which have been omitted in the new formula, probably for the good reason that they might not always be wanted, and that, should these or any similar oils be desired by any one, they might be readily added. In consequence of the use, in the former process, of diluted alcohol as a menstruum, much of the gummy and other principles soluble in water was extracted, rendering the resulting fluid extract inconveniently thick. Hence, in the arrangement of the present formula, alcohol was substituted; but, unfortunately, care was not taken sufficiently to get rid of this liquid; and the consequence has been that, though the extract when freshly prepared is sufficiently liquid, yet it soon begins to deposit saccharine matter, and in the end becomes so loaded with granular sugar as to be unfit for use. To obviate this result, Prof. Procter proposes to modify the process by allowing the first tincture to be reduced by spontaneous evaporation to *five* instead of six fluidounces, and by evaporating the second tincture made with diluted alcohol only to *eight* instead of six fluidounces; thus diminishing the proportion of alcohol and increasing that of

water. (*Proceed. of the Amer. Pharm. Assoc.*, 1863, p. 239.) At best, however, the preparation is inconveniently thick, though excellent in other respects, having the flavour of the root in perfection. The substitution of glycerin for the sugar in the preparation, as suggested by Mr. A. B. Taylor, would probably obviate this inconvenience. The colour of the officinal fluid extract is a deep reddish-brown, and even in dilution, as we have seen it, does not exhibit the yellow hue which might have been expected. This fluid extract may be used directly for obtaining the effects of rhubarb, but it is probably more employed in the preparation of the syrup. A fluidrachm of it should contain the virtues of a drachm of the root; and the dose, therefore, for an adult may be twenty or thirty minims as a purgative, and from five to ten minims as a laxative. W.

EXTRACTUM SARSAPARILLÆ FLUIDUM. *U. S.* Extractum Sarsæ Liquidum. *Br.* *Fluid Extract of Sarsaparilla.*

"Take of Sarsaparilla, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *ten troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Sarsaparilla with half a pint of Diluted Alcohol, pack it firmly in a cylindrical percolator, and gradually pour upon it Diluted Alcohol until four pints of tincture have been obtained. Evaporate this, by means of a water-bath, to a pint; then add the Sugar, and continue the evaporation until the liquid is reduced to the measure of a pint, and strain while hot." *U. S.*

"Take of Jamaica Sarsaparilla, cut transversely, *one pound* [avoirdupois]; Distilled Water, at 160°, *fourteen pints* [Imperial measure]; Rectified Spirit *one fluidounce.* Digest the Sarsaparilla in one-half of the Water for six hours, and decant the liquor. Digest the residue in the remainder of the Water for the same time, express, and filter the mixed liquors, and evaporate them by a water-bath to seven fluidounces, or until the sp. gr. of the liquid is 1·13. When cold, add the Spirit. The sp. gr. should be about 1·095." *Br.*

Of these two processes, that of the U. S. Pharmacopœia, except in respect to the high price of alcohol, is greatly preferable; and this objection will be in great measure obviated by recovering the alcohol, which can be done by using a distillatory apparatus in the evaporation. There can be no doubt that Sarsaparilla is more thoroughly exhausted when submitted, in the state of powder, to percolation with diluted alcohol, than it can be by maceration and subsequent digestion of the whole root in water, even though continued for twelve hours; the subsequent evaporation of the tincture requires less heat than that of the infusion, and thus less danger of injury is incurred from this cause; and the sugar is preferable as a preservative to alcohol, even admitting, what is scarcely probable, that the quantity of spirit directed in the Br. formula is sufficient to prevent decomposition, especially in our hot summer weather. There is some difficulty in properly mixing the powder with the menstruum, as it is apt to agglutinate in lumps; but this can be obviated by suitable manipulation, and a uniformly moistened mass obtained. If care be taken to have the powder of the due degree of fineness, to moisten it uniformly, and to pack it well in the percolator, it will be exhausted by a smaller amount of diluted alcohol than that indicated in the U. S. formula. The introduction of a simple fluid extract of sarsaparilla into our Pharmacopœia was judicious; as it enables the physician to associate this medicine with others at his pleasure, and in such proportions as he may deem expedient. He may rely upon the efficiency of the preparation, if made with sufficient care and skill, and from good parcels of the root. The U. S. fluid extract is a somewhat thickish, turbid, but sufficiently mobile liquid, of a dark reddish-brown colour, and of a sweet and a slightly though persistently acrid taste. The dose is from thirty to sixty minims, equivalent to the same number of grains of sarsaparilla in substance. The dose of the British preparation is stated in the Pharmacopœia to be from two to four fluidrachms. W.

EXTRACTUM SARSAPARILLÆ FLUIDUM COMPOSITUM. *U. S.* Extractum Sarsaparillæ Fluidum. *U. S.* 1850. *Compound Fluid Extract of Sarsaparilla.*

"Take of Sarsaparilla, in moderately fine powder, *sixteen troyounces;* Liquo-

rice Root, in moderately fine powder, Bark of Sassafras Root, in moderately fine powder, each, *two troyounces;* Mezereon, in moderately fine powder, *three hundred and sixty grains;* Sugar *twelve troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with ten fluidounces of Diluted Alcohol, pack it firmly in a cylindrical percolator, and gradually pour upon it Diluted Alcohol until four pints of tincture have been obtained. Evaporate this, by means of a water-bath, to twelve fluidounces; then add the Sugar, and continue the evaporation until the liquid is reduced to the measure of eighteen fluidounces, and strain while hot." *U. S.*

This is the Extractum Sarsaparillæ Fluidum of the U. S. Pharmacopœia of 1850, now necessarily entitled "Compositum," to distinguish it from the simple fluid extract newly introduced. The present is a much neater formula than the old one by maceration, but more liable to miscarry unless skilfully executed. Everything depends upon having the several ingredients equably powdered, mixing them well and duly moistening them, and then packing them properly in the percolator. The moistening of the mixed powders is more easily effected, as they are less disposed to form lumps than the sarsaparilla powder alone. The preparation is intended to represent, in a concentrated state, the compound decoction of sarsaparilla, having all its ingredients with the exception of the guaiacum wood, which probably adds little to the efficacy of the decoction. It was originally proposed by Wm. Hodgson, Jun. (*Journ. of the Philad. Col. of Pharm.*, ii. 285); and the officinal process differs from his mainly in the omission of the guaiacum wood, the resin of which, separating during the evaporation, somewhat embarrassed the process, without adding to the virtues of the extract. The dose is from thirty minims to a fluidrachm, equivalent to half a drachm or a drachm of the root, three or four times a day. W.

EXTRACTUM SENNÆ FLUIDUM. *U. S. Fluid Extract of Senna.*

"Take of Senna, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Senna with six fluidounces of Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until a pint of tincture has passed. Set this aside in a warm place until reduced by spontaneous evaporation to half a pint. Continue the percolation until two pints more of tincture have been obtained. To this add the Sugar, and, having evaporated it, by means of a water-bath, to half a pint, mix it with the reserved tincture, and strain." *U. S.*

The present officinal fluid extract of senna differs materially from that of the Pharmacopœia of 1850, containing neither the oil of fennel before used as a flavouring material, nor the Hoffmann's anodyne which was added for its preservative influence. It was deemed better to leave to the prescriber the choice of the volatile oil; and to depend for the preservation of the fluid extract upon the sugar and what might remain of the alcohol after the evaporation. Another alteration, undoubtedly judicious, was to set aside the first strong tincture for spontaneous evaporation, thus avoiding the application of heat to the greater portion of the active matter. The fluid extract is a dark, reddish-brown, thickish and somewhat turbid liquid, with a strong flavour of senna. The dose is from one to four fluidrachms for an adult. In consequence of its griping tendency it should be mixed with one of the volatile oils, as of fennel, anise, or caraway, in the proportion of about two minims to the fluidounce; and is well adapted for exhibition with saline cathartics, such as Epsom salt or cream of tartar, which also obviate its griping. In this case not more than one-half of the full dose of the fluid extract should be given at once.

Off. Prep. Extractum Spigeliæ et Sennæ Fluidum, *U. S.* W.

EXTRACTUM SERPENTARIÆ FLUIDUM. *U. S. Fluid Extract of Serpentaria.*

"Take of Serpentaria, in moderately fine powder, *sixteen troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Serpentaria with five fluidounces of

Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, at a temperature not exceeding 150°, until it is reduced to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

This is among the new officinal fluid extracts, and, though simply a concentrated tincture, is a good preparation, containing the virtues of the root within a small bulk. The fluid extract of serpentaria originated with Mr. J. C. Savery, whose formula was published in the eleventh edition of the U. S. Dispensatory (*page* 713). It was afterwards modified by Mr. A. B. Taylor (*Am. Journ. of Pharm.*, xxv. 206); and the formula ultimately adopted was that contained in Prof. Procter's Report (A. D. 1859). The fluid extract is thin, reddish-brown, and transparent, with the peculiar bitterness of the root in perfection, but its odour less obviously. A fluidounce of it is equivalent to a troyounce of the powder, and the dose is twenty or thirty minims, to be frequently repeated. W.

EXTRACTUM SPIGELIÆ ET SENNÆ FLUIDUM. *U. S. Fluid Extract of Spigelia and Senna.*

"Take of Fluid Extract of Spigelia *ten fluidounces;* Fluid Extract of Senna *six fluidounces;* Carbonate of Potassa *half a troyounce;* Oil of Anise, Oil of Caraway, each, *twenty minims.* Mix the Fluid Extracts, and dissolve in the mixture the Carbonate of Potassa and the Oils, previously rubbed together." *U. S.*

This fluid extract was formerly made from powdered pinkroot and senna by percolation and concentration; but it is now more conveniently prepared by simply mixing the two fluid extracts. It combines the cathartic property of senna with the anthelmintic virtues of pinkroot, and is a very good vermifuge, being generally acceptable to the stomach, and, what is of no little importance in such medicines, not offensive to the taste. It has been in use in Philadelphia for several years, and with satisfactory results. The use of the carbonate of potassa is to enable any resinous matter which may be deposited to be dissolved, and also to counteract the griping property of the senna. The dose is from two fluidrachms to half a fluidounce for an adult, from thirty minims to a fluidrachm for a child two years old. W.

EXTRACTUM SPIGELIÆ FLUIDUM. *U. S. Fluid Extract of Spigelia.*

"Take of Spigelia, in fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Spigelia with six fluidounces of Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until a pint of tincture has passed. Set this aside in a warm place until it is reduced by spontaneous evaporation to half a pint. Continue the percolation until two pints more of tincture have been obtained. To this add the Sugar, and, having evaporated it, by means of a water-bath, to half a pint, mix it with the reserved tincture, and strain." *U. S.*

This process is the same as that for the fluid extract of senna, and yields a dark-brown, translucent, syrupy liquid, with the flavour of the root. A fluidounce of it represents the virtues of a troyounce of spigelia, and the dose of it is one or two fluidrachms for an adult, from ten to twenty minims for a child two or three years old, to be repeated morning and evening for three or four days, and then followed by a brisk cathartic. It is, however, most used in connection with the fluid extract of senna.

Off. Prep. Extractum Spigeliæ et Sennæ Fluidum, *U. S.* W.

EXTRACTUM TARAXACI FLUIDUM. *U. S. Fluid Extract of Dandelion.*

"Take of Dandelion, in moderately fine powder, *sixteen troyounces;* Diluted

Alcohol *a sufficient quantity.* Moisten the Dandelion with four fluidounces of Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until half a pint of tincture has passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, at a temperature not exceeding 120°, until it is reduced to half a pint, mix it with the reserved tincture, and filter through paper." *U. S.*

This is a concentrated tincture of dandelion, containing only about one-fourth by measure of officinal alcohol, and therefore weak in alcoholic strength, yet strong enough to keep well. The formula is based on sound principles, and the fluid extract, if well prepared from the root in an efficient state, may be relied on for producing the effects of the medicine on the system. It is mobile, of a dark reddish-brown colour, translucent, and a sweet not disagreeable taste; and may be given in the dose of one or two fluidrachms three times a day. W.

EXTRACTUM UVÆ URSI FLUIDUM. *U. S. Fluid Extract of Uva Ursi.*

"Take of Uva Ursi, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Uva Ursi with six fluidounces of Diluted Alcohol, introduce it into a conical glass percolator, press it firmly, and gradually pour upon it Diluted Alcohol until half a pint of tincture has passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, by means of a water-bath, to four fluidounces, and, having dissolved the Sugar in it while hot, mix it with the reserved tincture, and strain. Lastly, evaporate the whole by a gentle heat until it is reduced to a pint." *U. S.*

Like the preceding, this is a concentrated tincture, in which the aid of sugar is called in apparently to contribute to its preservation, though scarcely required for the purpose, as it contains nearly 20 per cent. of officinal alcohol. The saccharine constituent, however, unless it may granulate, is useful by improving the flavour of the medicine. It is a thickish, syrupy, dark-brown, somewhat translucent liquid, of a sweet, bitterish, astringent, but not very disagreeable taste. The dose of this preparation is from thirty minims to a fluidrachm three times a day. W.

EXTRACTUM VALERIANÆ FLUIDUM. *U. S. Fluid Extract of Valerian.*

"Take of Valerian, in fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the Valerian with six fluidounces of Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour Alcohol upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this to four fluidounces at a temperature not exceeding 120°, mix it with the reserved tincture, and filter through paper." *U. S.*

This is another concentrated tincture, strong both in alcohol and the virtues of valerian. It is probable that all or nearly all the volatile ingredients of the root are extracted by the twelve fluidounces of alcohol which first pass, and which, not being exposed to evaporation, lose none of the volatile oil and acid which they have dissolved; while the soluble matter subsequently extracted, consisting chiefly of the fixed principles, will not be dissipated by the concentration ordered; and, as this is directed to be made at a heat not exceeding 120°, even the volatile principles which may have escaped the first alcohol, will scarcely be driven off to an appreciable amount. The fluid extract may, therefore, be considered as fully representing the virtues of the root. The formula is, with some modification, that of Prof. Grahame, late of Baltimore, now of Philadelphia, published in the *Am. Journ. of Pharm.* (xxxi. 379). The preparation is a dark soot-coloured liquid, transparent in thin layers, with the smell and taste of valerian. The dose is about a fluidrachm. W.

EXTRACTUM VERATRI VIRIDIS FLUIDUM. *U. S.* *Fluid Extract of American Hellebore.*

"Take of American Hellebore, in fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the Hellebore with six fluidounces of Alcohol, introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until half a pint of tincture has passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to half a pint, mix it with the reserved tincture, and filter through paper." *U. S.*

It may be doubted whether this fluid extract is among those demanded by the wants of the profession. We have already a tincture, which, supposing none of the virtues of the medicine to be lost in preparing the fluid extract, will be at least half as strong, and at all events is quite strong enough. It is true that the proportion of alcohol is somewhat less in the fluid extract; but, in so powerful a preparation, this is of little consequence. The tincture itself purports to be saturated; and, though it is probable that, by the concentration of the alcoholic solution, more of the active matter is held by it in the same measure of alcohol than by the tincture; yet a portion of this active matter may be deposited during the evaporation; and, as the deposit is separated by the filtration, no accurate ground of calculation is left as to the real strength of the fluid extract. It may be but little stronger than the tincture, or may possibly be of double the strength; a point which can be determined only by analysis, or physiological experiment, to ascertain how much, if any, of the active matter may be contained in the separated deposit. In the mean time, it would be injudicious to prescribe more of it, as a commencing dose, than from two to four minims. W.

EXTRACTUM ZINGIBERIS FLUIDUM. *U.S.* *Fluid Extract of Ginger.*

"Take of Ginger, in fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the Ginger with four fluidounces of alcohol, introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until twenty fluidounces more of tincture have been obtained. Evaporate this to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

The fluid extract of ginger is a highly concentrated alcoholic solution of the active principles of ginger. It is transparent, and of a reddish-brown colour; and each minim represents a grain of the root. The dose, therefore, is from ten to twenty minims, or double the number of drops. W.

FEL BOVINUM.

Preparation of Ox-gall.

In the British Pharmacopœia of 1864, crude Ox Bile was placed in the *Appendix*, as one of the substances used in preparing medicines; and, in the second part of the work, the following process was given for its purification. In the present edition the crude bile is referred to solely as the source of the purified, which is defined to be "the purified gall of the Ox, Bos Taurus," and is prepared in the same manner as before.

FEL BOVINUM PURIFICATUM. *Br.* *Purified Ox Bile.*

"Take of Fresh Ox Bile *one pint* [Imperial measure]; Rectified Spirit *two pints* [Imp. meas.]. Mix the Bile and the Spirit by agitation in a bottle, and set aside for twelve hours until the sediment subsides. Decant the clear solution, and evaporate it in a porcelain dish by the heat of a water-bath, until it acquires a suitable consistence for forming pills." *Br.*

The properties and uses of Ox Bile are fully treated of in *Part* III. of this

work (see *Ox-gall*). The purified bile is sometimes used in cases of debility of the alimentary canal in which the due proportion of bile is wanting. The dose is from two to five grains, and is best given in pill, as there is some chance that it may then pass unchanged into the bowels, where its effects are wanted. W.

FERRUM.

Preparations of Iron.

In accordance with the U. S. Pharmacopœia, we arrange all the preparations of iron under the several heads to which, by the character of the preparation, they appear to belong; the pills, for example, with the Pilulæ or Pills, and the solutions with the Liquores or Solutions. Formerly some of them were distributed according to this plan of arrangement, others were treated of among the preparations of iron. The rule is now made uniform. The preparations of iron considered elsewhere than in the present place are *Plaster of Iron*, with the Emplastra or *Plasters; Aromatic and Compound Mixtures of Iron*, with the Misturæ or *Mixtures; Solutions of Citrate, Iodide, Nitrate, Perchloride, Persulphate, Subsulphate*, and *Tersulphate of Iron*, with the Liquores or *Solutions; Pills of Aloes and Iron*, and *of Carbonate of Iron, Compound Pills of Iron*, and *Pills of Iodide of Iron*, with the Pilulæ or *Pills; Syrups of Iodide* and *Phosphate of Iron* with the Syrupi or *Syrups; Tinctures of Acetate* and *of Chloride of Iron* with the Tincturæ or *Tinctures; Troches of Reduced Iron*, and *of Carbonate of Iron*, with the Trochisci or *Troches;* and the *Wine of Iron* and *Wine of Citrate of Iron*, with the Vina or *Wines*. The preparations contained in the old Pharmacopœias, and omitted in the present, are the *Sulphuret of Iron*, Ed., Dub., the *Valerianate of Iron*, Dub., the *Ammoniated Iron*, U. S., Lond.; and the *Tincture of Ammonio-chloride of Iron*, Lond.

FERRI ARSENIAS. *Br.* *Arseniate of Iron.*

"Take of Sulphate of Iron *nine ounces* [avoirdupois]; Arseniate of Soda, dried at 300°, *four ounces* [avoird.]; Acetate of Soda *three ounces* [avoird.]; Boiling Distilled Water *a sufficiency*. Dissolve the Arseniate and Acetate of Soda in *two pints* [Imperial measure], and the Sulphate of Iron in *three pints* [Imp. meas.] of the Water, mix the two solutions, collect the white precipitate which forms, on a calico filter, and wash until the washings cease to be affected by a dilute solution of chloride of barium. Squeeze the washed precipitate between folds of strong linen in a screw press, and dry it on porous bricks, in a warm chamber whose temperature shall not exceed 100°." *Br.*

This is an officinal of the first British Pharmacopœia, which as yet is the only one that has adopted it. Of the salts used in the process, omitting their water of crystallization, the sulphate of iron consists of one eq. of protoxide of iron and one of sulphuric acid, the arseniate of soda of two eqs. of soda and one eq. of arsenic acid, and the acetate of soda of one eq. of base and one of acid; while the salt to be obtained consists of three eqs. of protoxide of iron and one of arsenic acid. The reactions which result in the production of the last-mentioned salt take place between three eqs. of sulphate of iron and one eq. of each of the other salts. The three eqs. of protoxide of iron of the sulphate unite with the one eq. of arsenic acid of the arseniate to form one eq. of arseniate of iron, which is deposited; while the three eqs. of sulphuric acid, thus liberated, combine with the two liberated eqs. of soda of the arseniate of soda, and one eq. of soda of the acetate, to make three eqs. of sulphate of soda, which, with the separated acetic acid, remain in solution. The quantities of the several salts are very nearly in due equivalent proportion; the arseniate and acetate of soda, however, being very slightly in excess.

Arseniate of iron is white when first formed, but quickly becomes green on exposure to the air. It is an amorphous powder, without smell or taste, insoluble in water, but readily dissolved by muriatic acid. It consists of three eqs. of protoxide of iron and one of arsenic acid ($3FeO,AsO_5$), but, like other salts of protoxide of iron, absorbs oxygen, and probably, therefore, contains an indefi-

nite proportion of sesquioxide of iron. The British Pharmacopœia gives the following characters of the salt. Its solution in muriatic acid causes a copious light-blue precipitate with the yellow prussiate of potash (ferrocyanide of potassium), and a still more abundant one, of a deeper colour, with the red prussiate of potash (ferridcyanide of potassium). A small quantity, boiled with an excess of soda, and filtered, gives, when exactly neutralized by nitric acid, a brick-red precipitate on the addition of solution of nitrate of silver. The former test proves the presence both of protoxide and sesquioxide of iron, the latter of arsenic acid. The solution in muriatic acid, when diluted, gives no precipitate with chloride of barium, showing the absence of any sulphate. "Twenty grains dissolved in an excess of hydrochloric acid diluted with water continue to give a blue precipitate with the red prussiate of potash (ferridcyanide of potassium), until at least 170 grain-measures of the *volumetric solution of bichromate of potash* have been added." *Br.* This test proves that there is a due proportion of the protoxide of iron present; for the bichromate of potassa oxidizes the protoxide, and, until this is wholly converted into sesquioxide, a blue precipitate continues to be produced, ceasing, however, when the conversion is complete.

Medical Properties. The arseniate of iron is said to unite the virtues of the two metals which enter into its composition; but the quantity of iron in any permissible dose is so small as to be nearly or quite insignificant; and the activity of the medicine is in fact due to the arsenic alone. The complaints in which it has been found efficient are those in which arsenic in other forms has proved to be a most valuable remedy; and, judging from our own observation, there is no one of them in which the common solution of arsenite of potassa will not produce all the effects that can be obtained from the arsenical preparations, with which this ought undoubtedly to be ranked rather than with the chalybeates. Should the coexistence of an anemic state of the system with any disease requiring the use of arsenic, indicate the joint use of iron, it would be unsafe to depend on the arseniate of iron alone. This remedy is peculiarly useful in chronic affections of the skin, especially those of a scaly character, as lepra, psoriasis, and the advanced stage of eczema and impetigo. It is useful also in lupus; and, mixed with twelve times its weight of simple cerate, may be employed externally in cancerous ulcers, though much caution is requisite. The dose is from the eighth to the tenth of a grain, of which about one-half only is protoxide of iron. It may be given in pill, three times a day. W.

FERRI CARBONAS SACCHARATA. *Br. Saccharated Carbonate of Iron.*

"Take of Sulphate of Iron *two ounces* [avoirdupois]; Carbonate of Ammonia *one ounce and a quarter* [avoird.]; Boiling Distilled Water *two gallons* [Imperial measure]; Refined Sugar *one ounce* [avoird.]. Dissolve the Sulphate of Iron and the Carbonate of Ammonia each in half a gallon [Imp meas.] of the Water, and mix the two solutions with brisk stirring in a deep cylindrical vessel, which is then to be covered as accurately as possible. Set the mixture by for twenty-four hours, and from the precipitate which has subsided separate the supernatant solution by a siphon. Pour on the remainder of the Water, stir well, and, after subsidence, again remove the clear solution. Collect the resulting carbonate on a calico filter, and, having first subjected it to expression, rub it with the Sugar in a porcelain mortar. Finally dry the mixture at a temperature not exceeding 212°." *Br.*

When solutions of sulphate of iron and carbonate of soda are mixed together, there are formed, by double decomposition, sulphate of soda which remains in solution, and carbonate of protoxide of iron which falls as a pale-blue precipitate. This precipitate begins immediately to alter in nature by the absorption of oxygen, and, if washed and dried in the ordinary way, becomes sesquioxide of iron, associated with a small quantity of the carbonate of the protoxide, which has escaped change; in other words, it is converted into the subcarbonate of iron of the U. S. Pharmacopœia. (See *Ferri Subcarbonas.*) As the preparations

of iron containing the protoxide are most esteemed, the change which this precipitate undergoes was always matter of regret, and various attempts were made to prevent it. Now saccharine matter has been ascertained to possess the required property; and, in the preparation under consideration, it is used to prevent the protoxide of iron of the carbonate as first precipitated from passing into sesquioxide, with loss of carbonic acid.

Dr. Becker, a German physician, was the first to suggest the use of saccharine matter as a means of protection against the absorption of oxygen; and the idea was carried out by Klauer, a German chemist, who first made the saccharine carbonate of iron. The use of boiling distilled water in the process is to avoid the action of the air contained in unboiled water. The washed precipitate is pressed so as to free it from water as far as possible, and then incorporated with the sugar in fine powder. The mode of treating the precipitate unnecessarily exposes it to the action of the air; and the late London method of incorporating it with the sugar immediately after washing was on this account preferable. The final drying heat should not exceed 130°. The protection from oxidation, however, is more complete, when both the materials and product of the process are maintained constantly in contact with saccharine matter, by using weak syrup both for dissolving the salts and washing the precipitate, after the improved method of Vallet, of Paris. This improved method of proceeding is adopted for forming the U. S. pills of carbonate of iron, or Vallet's ferruginous pill. (See *Pilulæ Ferri Carbonatis, U. S.*)

Properties. Saccharine carbonate of iron is in small coherent lumps, of a grayish-brown colour, permanent in the air, having a sweet, styptic taste, and wholly and readily soluble in muriatic acid with brisk effervescence. According to the British Pharmacopœia, it is a "carbonate of iron (FeO,CO_2), mixed with peroxide of iron and sugar, and forming at least 57 per cent. of the mixture." The presence of sesquioxide of iron is a defect, which is avoided in Vallet's ferruginous pills.

Its solution in dilute muriatic acid is but slightly affected by ferrocyanide of potassium, showing the presence of the sesquioxide of iron in only small proportion, but yields a copious blue precipitate with the ferridcyanide, proving the abundance of the protoxide. The same solution should give but a very slight precipitate with chloride of barium, evincing that very little sulphate either of iron or soda has escaped the washing process. "Twenty grains dissolved in excess of hydrochloric acid, and diluted with water, continue to give a blue precipitate with red prussiate of potash until at least 330 grain-measures of the *volumetric solution of bichromate of potash* have been added." *Br.* This test determines the quantity of protoxide of iron present, requiring the stated amount of the bichromate to convert it into sesquioxide.

Medical Properties. This preparation is an excellent chalybeate, possessing the advantages of having nearly all the iron in it in the state of protoxide, and of being readily soluble in acids. Originally introduced into the officinal list by the Edinburgh College, it appeared for the first time in the Dublin and London Pharmacopœias of 1850 and 1851. It is probably more active than the subcarbonate of iron, and must be used in a smaller dose. It is, however, inferior to Vallet's ferruginous mass, in the preparation of which the anti-oxidizing influence of saccharine matter is more fully applied. The dose of the saccharine carbonate of iron is from five to thirty grains, given in the form of pill.

Off. Prep. Pilula Ferri Carbonatis, *Br.* B.

FERRI CHLORIDUM. *U. S.* *Chloride of Iron. Sesquichloride of Iron. Perchloride of Iron.*

"Take of Iron, in the form of wire and cut in pieces, *two troyounces;* Muriatic Acid *twelve troyounces;* Nitric Acid *a troyounce,* or *a sufficient quantity.* To eight troyounces of the Muriatic Acid, introduced into a two-pint flask, add the Iron, and apply a gentle heat, until the Acid is saturated and effervescence has ceased. Filter the solution, add to it the remainder of the Muriatic Acid,

heat the mixture nearly to the boiling point in a four-pint porcelain capsule, and add Nitric Acid in successive portions until red fumes are no longer evolved, and a drop of the liquid ceases to yield a blue precipitate with ferridcyanide of potassium. Transfer the liquid to a smaller capsule, evaporate it by a gentle heat, on a sand-bath, until reduced to eight troyounces and three hundred and sixty grains, and set it aside, covered with glass, for several days, in order that it may form a solid, crystalline mass. Lastly, break this into pieces, and keep the fragments in a well-stopped bottle protected from the light." *U. S.*

This is a new formula of the U. S. Pharmacopœia, adopted with little alteration from that of Wittstein. (*Pract. Pharm. Chem., Darby's Transl.* p. 265.) When iron is heated with muriatic acid, water is decomposed, the hydrogen escapes with effervescence, and the oxygen uniting with the iron forms the protoxide of that metal, which reacts with the muriatic acid to form water and protochloride of iron. This is believed by the author to be the true rationale; though a simpler explanation is usually given, according to which the chlorine of the acid unites directly with the iron, and the hydrogen is set free. The next step of the process is to convert the protochloride into the sesquichloride of iron. This is effected by treating it with muriatic and nitric acids, and heating till red fumes no longer escape. The nitric acid is decomposed into nitric oxide, which, escaping, forms red hyponitric acid fumes by combining with the oxygen of the air, and into oxygen which sesquioxidizes a portion of the iron of the protochloride, thus converting the remainder into sesquichloride, while the sesquioxide produced reacts with the additional muriatic acid to form an additional portion of sesquichloride; or the oxygen of the nitric acid may combine with the hydrogen of the muriatic acid, and thus liberate sufficient chlorine to form a sesquichloride with the iron. The solution is then evaporated, and, on cooling, concretes into a crystalline mass. The relative proportions of iron and the two acids are adjusted very nearly to the production of these results.

Properties. Sesquichloride of iron (Ferri Chloridum, *U. S.*) is in fragments of a crystalline structure, an orange-yellow colour, inodorous, and of a strong chalybeate and styptic taste. It is deliquescent, very soluble in water, and soluble also in alcohol and ether. It consists of two eqs. of iron and three of chlorine (Fe_2Cl_3), with a variable proportion of water according to the crystalline forms it is made to assume, having about 40 per cent. or 12 eqs. when in fine acicular crystals, and only 22 per cent. or five eqs. when in the form of larger tables. (*Brande and Taylor.*) Its solution in water gives with ammonia a brown precipitate of sesquioxide of iron, and does not yield a blue one with the ferridcyanide of potassium, proving the absence of protochloride or protoxide of iron.

Internally the sesquichloride of iron is used almost exclusively in the form of tincture; and in reference to its effect and application we refer to the *Tinctura Ferri Chloridi.* Externally it is as generally used in the form of watery solution; and as the British Pharmacopœia has an officinal solution, which it will be necessary to treat of under a special head, we shall postpone a further consideration of the subject till this preparation is treated of. (See *Liquor Ferri Perchloridi.*) It is kept in the solid state, because, when dissolved, it is apt to deposit sesquioxide of iron (oxychloride of iron, *Brurin du Buisson*) in an insoluble condition, whereby an excess of acid is produced, which renders the preparation too irritant for many of the purposes for which it is used. (Squibb, *N. Y. Journ. of Med.*, March, 1860, p. 170.) As a solid, it keeps indefinitely without change. When used, it may be dissolved in water in such proportions as may be required. Six, three, two, and one and a half drachms to a fluidounce of water have been recommended; the stronger solutions being used in the treatment of varices, the weaker for injection into aneurisms, and for application to bleeding surfaces, &c. Mr. J. Z. Lawrence, of England, has used it as a styptic in a semi-deliquesced state, and found it extremely efficient. He keeps it in a bottle, in which it gradually deliquesces; and, while it is in this condition, he applies the thick liquid portion, by means of a brush of spun-glass, to the bleed-

ing surface. He has employed it in arresting hemorrhage after excision of the tonsils, and from the deeper-seated gums. (*Med. Times and Gaz.*, Aug. 1859, p. 219.) Chloride of iron has been employed internally, by Messrs. Jodin and Aubrun, of Paris, and with great asserted success, in the treatment of pseudo-membranous croup, in quantities varying, according to the severity of the disease and the age of the patient, from ninety grains to half an ounce, in divided doses, in the twenty-four hours, and continued for three or four days. (*Ann. de Thérap.*, 1861, p. 201.) W.

FERRI CITRAS. *U.S.* *Citrate of Iron.*

"Take of Solution of Citrate of Iron *a convenient quantity*. Evaporate it to the consistence of Syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

Citrate of iron, as thus prepared, is in thin transparent pieces, of a beautiful garnet-red colour. It is an uncrystallizable salt, slowly soluble in cold, but readily soluble in boiling water, and possessing a mild chalybeate taste. It probably consists of one eq. of citric acid 165, and one of sesquioxide of iron 80 = 245.

Citrate of iron was introduced to the notice of the profession, in 1831, by M. Béral, of Paris. It is a pleasant chalybeate, and is best given in solution. Prof. Procter finds that a solution of this salt in distilled water, containing 240 grains in a fluidounce, keeps perfectly, and is very convenient for dispensing. It may be given in the dose of ten minims, containing five grains of the salt, several times a day. (See *Liquor Ferri Citratis.*) B.

FERRI ET AMMONIÆ CITRAS. *U. S.*, *Br.* *Citrate of Iron and Ammonia.*

"Take of Solution of Citrate of Iron *a pint;* Water of Ammonia *six fluidounces*. Mix the Solution of Citrate of Iron with the Water of Ammonia, evaporate the mixture, at a temperature not exceeding 150°, to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

"Take of Solution of Persulphate of Iron *eight fluidounces;* Solution of Ammonia *nineteen and a half fluidounces;* Citric Acid *four ounces* [avoirdupois]; Distilled Water *a sufficiency*. Mix fourteen fluidounces of the Solution of Ammonia with two pints [Imperial measure] of Distilled Water, and to this add gradually the Solution of Persulphate of Iron, previously diluted with two pints [Imp. meas.] of Distilled Water, stirring them constantly and briskly. Let the mixture stand for two hours, stirring it occasionally, then put it on a calico filter, and when the liquid has drained away, wash the precipitate with Distilled Water until that which passes through the filter ceases to give a precipitate with chloride of barium. Dissolve the Citric Acid in eight [fluid]ounces of Distilled Water, and having applied the heat of a water-bath, add the oxide of iron, previously well drained, and stir them together until the whole or nearly the whole of the oxide has dissolved. Let the solution cool, then add five and a half fluidounces of Solution of Ammonia. Filter through flannel, evaporate to the consistence of syrup and dry it in thin layers on flat porcelain or glass plates at a temperature not exceeding 100°. Remove the dry salt in flakes, and keep it in a stoppered bottle." *Br.*

In the U. S. Pharmacopœia, the process consists simply in evaporating a mixture of solution of citrate of iron and water of ammonia. In the British, hydrated sesquioxide of iron is first precipitated from a solution of the tersulphate, then digested at a boiling heat with a solution of citric acid, and lastly neutralized by ammonia. It has, however, been found by Dr. Squibb that a heat above 180° acts injuriously in the preparation of the citrate of iron; and the boiling heat directed in the British Pharmacopœia of 1864 was, therefore, improper. (*Am. Journ. of Pharm.*, xxvii. 297.) This error has been corrected in the present Pharmacopœia, which directs that the salt should be dried at a heat not above 100°. In the U. S. formula the citrate of iron is used already prepared, in the British is prepared in the process. The direction as to the

evaporation, at the close of the original British process, was not sufficiently explicit. The solution should be concentrated to a syrupy consistence, as ordered in the U. S. and existing British formulas, before being poured out on porcelain or glass to dry; and it is important that the heat employed in the concentration should not exceed 150°.

Properties, &c. Ammonia-citrate of iron is in garnet-red translucent scales, having a slightly chalybeate taste, and readily and wholly soluble in water, forming a solution of a clear ruby colour. It is much more readily soluble in water than the citrate of iron, described in the last article. It is almost insoluble in alcohol. It is neutral to test paper ("feebly reddens litmus paper," *Br.*); and its solution in water, acidulated with muriatic acid, though not rendered blue by ferridcyanide of potassium, gives a copious blue precipitate with the ferrocyanide, at once proving the absence of protoxide of iron and the presence of the sesquioxide. In heated solution it is decomposed by potassa, soda, and lime-water, which throw down sesquioxide of iron and evolve ammonia; and the alkaline solution from which the iron has been thrown down, if acidulated with muriatic acid in slight excess, does not yield a crystalline deposit, showing that the acid is not the tartaric. When incinerated in the air, it leaves 26·5 per cent. (not less than 27 per cent., *Br.*) of peroxide of iron. Its precise chemical constitution is not determined; but it probably consists of one eq. of each of its three constituents, besides water ($Fe_2O_3,NH_4O,HO,C_{12}H_5O_{11}+2HO$). (*Br.* 1864.) This salt is a pleasant chalybeate. Its ready solubility gives it an advantage over the citrate. The dose is five grains, repeated several times a day, and given in solution. According to Dr. Paris, it may be mixed with the carbonated alkalies without decomposition, and given in a state of effervescence with citric acid.

Off. Prep. Vinum Ferri Citratis, *Br.* B.

FERRI ET AMMONIÆ SULPHAS. *U.S.* *Sulphate of Iron and Ammonia. Ammonio-ferric Alum.*

"Take of Solution of Tersulphate of Iron *two pints;* Sulphate of Ammonia *four troyounces and a half.* Heat the Solution of Tersulphate of Iron to the boiling point, add the Sulphate of Ammonia, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air." *U. S.*

This is an ammonia iron-alum, in which the place of the sesquioxide of aluminium (alumina) is occupied by sesquioxide of iron. It is prepared by heating the solution of tersulphate of iron with sulphate of ammonia until the latter salt is dissolved, and then allowing the solution to cool. The two salts unite to form the sulphate of iron and ammonia, which, being insoluble in the amount of liquid employed, crystallizes when it cools. The process is based on one published by Wm. Hodgson, jun. in the *Am. Journ. of Pharm.* for July, 1856 (p. 305). The salt consists of one eq. of each of the two salts composing it, with probably 24 eqs. of water of crystallization ($Fe_2O_3,3SO_3+NH_4O,SO_3+24HO$).

Ammonio-ferric alum is in octohedral crystals, of a pale violet colour, and sour astringent taste, slowly efflorescent on exposure, and soluble in 1·5 parts of water at 60°, and in less than their weight of boiling water. The sulphuric acid is recognised by giving a precipitate with chloride of barium insoluble in nitric acid; the sesquioxide of iron by being thrown down of a reddish-brown colour, by potassa; and the ammonia, by the emission, when the moistened salt is rubbed with the same alkali, of its peculiar odour. According to H. Rose, the pure salt is white, and gives a coloured solution with water, in consequence of the formation of a basic ferruginous salt. This decomposition is prevented by dissolving it in dilute sulphuric acid, when the solution is colourless.

Instead of sulphate of ammonia, sulphate of potassa may be employed along with the tersulphate of iron, in which case a potassa iron-alum is produced, called *potassio-ferric alum,* which has all the properties, physical and remedial, of the ammonio-ferric salt; and the two appear to have been indiscriminately used. The formula of this salt would be $Fe_2O_3,3SO_3+KO,SO_3+24HO$.

The iron alums were brought to the notice of the Pharmaceutical Society of London, in Dec. 1853, by Mr. Lindsley Blyth, as a new remedy, prescribed in St. Mary's Hospital. Dr. Tyler Smith found them to be more astringent than common alum, and devoid of the stimulating effects of the other salts of iron. They have been used internally in leucorrhœa, with great asserted benefit, in diarrhœa and chronic dysentery, and in other affections requiring combined tonic and astringent treatment. (*Pharm. Journ.*, Jan. 1854, p. 306.) The dose is from three to twelve or fifteen grains, to be repeated twice or three times a day. B.

FERRI ET AMMONIÆ TARTRAS. *U. S.* *Tartrate of Iron and Ammonia.*

"Take of Tartaric Acid *twelve troyounces;* Solution of Tersulphate of Iron *two pints and a half;* Carbonate of Ammonia, Distilled Water, each, *a sufficient quantity.* Dissolve six troyounces of the Tartaric Acid in two pints of Distilled Water, and saturate it carefully by means of Carbonate of Ammonia; then add the remainder of the Acid, dissolved in half a pint of Distilled Water, and mix the solutions. With the Solution of Tersulphate of Iron, prepare the Hydrated Oxide of Iron according to the formula for that substance, and add it gradually to the solution of bitartrate of ammonia, kept at the temperature of 150°, until it is no longer dissolved. Then filter the solution, and evaporate to the consistence of syrup. Lastly, spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

This is a new officinal of the U. S. Pharmacopœia, adopted from Prof. Procter, whose process was published in the *American Journal of Pharmacy*, so long since as in 1841 (xii. 276). Tartrate of ammonia is first prepared, which is converted into bitartrate by the addition of tartaric acid; and the excess of acid is then combined with hydrated sesquioxide of iron freshly prepared from the officinal solution of the tersulphate. A double salt of tartrate of ammonia and tartrate of iron is thus made in solution, which is obtained by filtering and concentrating the solution. The bibasic view of tartaric acid requires a different explanation. According to this, the salt must be considered as consisting of one eq. of tartaric acid, with a doubled equivalent number, and two eqs. of base, one consisting of ammonia and the other of sesquioxide of iron. In the first view, it would be represented by the formula $Fe_2O_3,C_4H_2O_5+NH_4O,C_4H_2O_5$; in the second, by $Fe_2O_3,NH_4O+C_8H_4O_{10}$, independently of the water, which has been estimated between four and five equivalents.

This salt is in transparent garnet-red scales, which when powdered assume a rust-brown colour. It has a sweetish not disagreeable taste, and is very soluble in water though slowly, being taken up by somewhat more than its own weight. It is insoluble in alcohol and ether. Test paper is not affected by it. The fixed alkalies do not precipitate it from its solution, nor is it rendered blue by ferrocyanide of potassium, showing that it contains no protoxide of iron. Incinerated in the air, it leaves 29 per cent. of sesquioxide of iron. It is a mild chalybeate, and may be given in a dose of from ten to thirty grains. W.

FERRI ET POTASSÆ TARTRAS. *U. S.* FERRUM TARTARATUM. *Br.* *Tartrate of Iron and Potassa. Tartarated Iron. Potassio-tartrate of Iron.*

"Take of Solution of Tersulphate of Iron *a pint;* Bitartrate of Potassa *seven troyounces;* Distilled Water *four pints.* With the Solution of Tersulphate of Iron, prepare the Hydrated Oxide of Iron according to the formula for that substance. Mix the Bitartrate of Potassa with the Distilled Water, heat the mixture to 140°, and, keeping it at that temperature, gradually add the Hydrated Oxide, frequently stirring, until it ceases to be dissolved. Then filter the solution, evaporate it by means of a water-bath to the consistence of syrup, and spread it upon plates of glass or porcelain, so that, on drying, the salt may be obtained in scales." *U. S.*

"Take of Solution of Persulphate of Iron *five and a half fluidounces* [Imperial measure]; Solution of Ammonia *ten fluidounces* [Imp. meas.]; Acid Tartrate of Potash, in powder, *two ounces* [avoirdupois]; Distilled Water *a*

sufficiency. Mix the Solution of Ammonia with *three pints* [Imp. meas.] of Distilled Water, and to this add gradually the Solution of Persulphate of Iron previously diluted with two pints [Imp. meas.] of Distilled Water, stirring constantly and briskly. Let the mixture stand for two hours, stirring it occasionally, then put it on a calico filter, and when the liquid has drained away, wash the precipitate with Distilled Water until that which passes through the filter ceases to give a precipitate with chloride of barium. Mix the washed and drained precipitate intimately with the Acid Tartrate of Potash in a porcelain dish and let the mixture stand for twenty-four hours; then, having applied a gentle heat, not exceeding 140°, add gradually a pint [Imp. meas.] of Distilled Water, and stir constantly until nothing more will dissolve. Filter; evaporate at a temperature not exceeding 140° to the consistence of syrup, and dry it in thin layers on flat porcelain or glass plates in a drying closet at 120°. Remove the dry salt in flakes and keep it in stoppered bottles." *Br.*

The object of these processes is to combine the excess of acid in the bitartrate of potassa with sesquioxide of iron. In both, the plan of Soubeiran is adopted; namely, that of dissolving the moist hydrated sesquioxide to saturation in a mixture of the bitartrate and water, aided by a moderate heat. The sesquioxide is now obtained from the tersulphate of sesquioxide of iron, which is precipitated by ammonia. Potassa, which was used in the former British process, is not a good precipitant; because the alkali adheres obstinately to the precipitated sesquioxide, and cannot be completely separated even by repeated washings. The sesquioxide should be gradually added to the bitartrate and water, heated to 140°, as recommended by Soubeiran, at which temperature the oxide dissolves more readily and in larger quantity than when a higher temperature is employed. Besides, in the latter case, a portion of the sesquioxide is converted into protoxide. (*Gmelin's Handbook*, x. 315.) In both formulas, the liquid is poured out on a plane surface, so as to dry in scales. When duly carried into effect, they yield a product at all times identical, and having all the required qualities of the salt.*

The late Dr. Ure proposed the *tartrate of protoxide of iron* for medical use. He made it by acting on clean iron filings, or bits of iron wire, with a

* *A new method of preparing this salt.* M. Roger, having found the tartrate of iron and potassa, as existing in the shops of Paris, a very variable salt, seldom presenting perfect identity of composition in any two specimens, and ascribing this result to the imperfection of the prevalent mode of preparing it, which requires a large amount of water, and consequently a prolonged evaporation, resulting in the reduction of the sesquioxide, and the production of a yellowish insoluble ferrous salt, and is attended besides with various other inconveniences, proposes the following method, which he conceives to be free from these objections, and to present in all instances an identical product. The newly proposed method consists in causing, as a first step, strongly hydrated sesquioxide of iron to be dissolved in tartaric acid to complete saturation, for which purpose the water of hydration of the sesquioxide is sufficient at a temperature of 100° to 120° F. The solution takes place completely and quickly; and the point of saturation is known when the liquid, at first clear, becomes turbid, thickens, and at last concretes in the form of a jelly. No more of the sesquioxide, which is in slight excess, is now to be added. Upon this jelly is to be poured, little by little, a very concentrated solution of *pure* carbonate of potassa, of which the quantity to be used should be the equivalent of that of the tartaric acid employed. But this precision as to the quantity of the carbonate is not absolutely necessary; as the cessation of effervescence is a sufficient criterion of saturation. Should, however, the solution, upon testing it, be found slightly acid, the solution of carbonate of potassa should be cautiously added till the reaction becomes slightly alkaline. The vessel is then to be removed from the water-bath, and the liquid allowed to cool. Twelve hours afterwards, the liquid is decanted, filtered, and evaporated by means of a water-bath, with constant agitation, to a syrupy consistence. It is then to be spread by means of a brush, in thin layers, on plates of glass, which are to be placed in the drying room. The salt is thus obtained in beautiful spangles, of a deep garnet red. Or it may be dried in moulds of tinned iron with a large surface; but in this case, instead of scales, it forms little black masses not unlike jet. Thus prepared, it always presents the same composition, dissolves in water without residue, and, besides, is little disposed to deliquescence, so that it may be readily employed in pills. The solution, however, is slow in forming, as the salt at first agglomerates at the bottom of the vessel; but in half an hour it is complete, and may be kept long unchanged. (*Journ. de Pharm.*, Juin, 1861, p. 401.)—*Note to the twelfth edition.*

solution of tartaric acid. It is a pulverulent salt, insoluble in water, and possessing a mild chalybeate taste.

Properties. Tartrate of iron and potassa, as obtained by the above formulas, is in transparent scales of a ruby-red colour, wholly soluble in about four parts of water, and "sparingly soluble in spirit." *Br.* It has a sweetish slightly chalybeate taste. Its solution does not change the colour of litmus, and at common temperatures is not precipitated by potassa, soda, or ammonia. Ferrocyanide of potassium does not render it blue, unless an acid be added. The non-action of this test shows that the iron is in a peculiar state of combination. Acidulated with muriatic acid, the solution gives a copious blue precipitate with the ferrocyanide of potassium, but none with the ferridcyanide, showing the absence of protoxide of iron. In boiling solution, soda precipitates sesquioxide of iron, without evolution of ammonia; and the filtered solution, acidulated with muriatic acid, deposits a crystalline substance when it cools; the latter test showing the presence of tartrate of potassa, the former that of the sesquioxide of iron without ammonia, and both together the character of the salt. According to the view of its nature taken in the U. S. Pharmacopœia, it is a double salt, consisting of one eq. of tartrate of sesquioxide of iron and one of tartate of potassa ($Fe_2O_3,C_4H_2O_5+KO,C_4H_2O_5+HO$); according to the bibasic view of tartaric acid, it is a tartrate with a double base ($Fe_2O_3,KO,C_8H_4O_{10}+HO$), the eq. of tartaric acid being doubled. "By incinerating 50 grains at a red heat, washing what is left with distilled water, and again incinerating, a residue of peroxide is obtained, weighing 15 grains." (*Br.*) The salt is incompatible with astringent vegetable infusions, which give rise to a dark-coloured precipitate.

Medical Properties. Tartrate of iron and potassa is an agreeable chalybeate, and may be depended upon for activity and uniformity of composition. It has a somewhat laxative effect, which makes it suitable to the treatment of certain cases. It is the chalybeate preferred by M. Mialhe, who conceives that it is more readily absorbed than any other ferruginous preparation. It is also well borne by the stomach, whether taken fasting, or with the food. From its slight taste and ready solubility, it is one of the best ferruginous preparations for children. The dose for an adult is from ten grains to half a drachm, given preferably in solution. B.

FERRI ET QUINIÆ CITRAS. *U. S., Br. Citrate of Iron and Quinia.*

"Take of Solution of Citrate of Iron *ten fluidounces;* Sulphate of Quinia *a troyounce;* Diluted Sulphuric Acid, Water of Ammonia, Distilled Water, each, *a sufficient quantity.* Triturate the Sulphate of Quinia with six fluidounces of Distilled Water, and, having added sufficient Diluted Sulphuric Acid to dissolve it, cautiously pour into the solution Water of Ammonia, with constant stirring, until in slight excess. Wash the precipitated Quinia on a filter, and, having added it to the Solution of Citrate of Iron, maintained at the temperature of 120° by means of a water-bath, stir constantly until it is dissolved. Lastly, evaporate the solution to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

"Take of Solution of Persulphate of Iron *four and a half fluidounces;* Sulphate of Quinia *one ounce* [avoirdupois]; Diluted Sulphuric Acid *twelve fluidrachms* [Imperial measure]; Citric Acid *three ounces* [avoird.]; Solution of Ammonia, Distilled Water, of each, *a sufficiency.* Mix eight fluidounces [Imp. meas.] of the Solution of Ammonia with two pints [Imp. meas.] of Distilled Water, stirring them constantly and briskly. Let the mixture stand for two hours, stirring it occasionally, then put it on a calico filter, and when the liquid has drained away, wash the precipitate with Distilled Water until that which passes through the filter ceases to give a precipitate with chloride of barium.

"Mix the Sulphate of Quinia with eight [fluid]ounces of Distilled Water, add the Diluted Sulphuric Acid, and when the salt is dissolved precipitate the quinia with a slight excess of Solution of Ammonia. Collect the precipitate on a filter, and wash it with a pint and a half of Distilled Water.

"Dissolve the Citric Acid in five [fluid]ounces of Distilled Water, and, having applied the heat of a water-bath, add the oxide of iron previously well drained; stir them together, and when the oxide has dissolved, add the precipitated quinia, continuing the agitation until this also has dissolved. Let the solution cool, then add in small quantities at a time twelve fluidrachms of Solution of Ammonia diluted with two fluidounces of Distilled Water, stirring the solution briskly, and allowing the quinia which separates with each addition of ammonia to dissolve before the next addition is made. Filter the solution, evaporate it to the consistence of a thin syrup, then dry it in thin layers on flat porcelain or glass plates at a temperature of 100°. Remove the dry salt in flakes, and keep it in a stoppered bottle. *Br.*"

The U. S. process is based on a published formula of Prof. Procter, described in the eleventh edition of this Dispensatory (*page* 1393). It consists simply in dissolving, at a temperature of 120°, in a definite measure of solution of citrate of iron (U. S.), the quinia obtained by precipitating a given weight of sulphate of quinia by water of ammonia. The British process of 1864 was more complicated. First, a mixture of sesquioxide and protoxide of iron was obtained by precipitating a mixture of the sesquisulphate and sulphate in solution by means of soda. Secondly, the mixed oxides thus obtained were digested with a solution of citric acid, so as to produce in solution a citrate of the two oxides. Thirdly, sulphate of quinia, dissolved by means of dilute muriatic acid, was precipitated by chloride of barium so as to separate the sulphuric acid, and from the solution of the muriate of quinia remaining, the quinia was thrown down by ammonia. Lastly, the quinia thus procured was digested with the solution of citrate of iron, and the resulting citrate of iron and quinia was obtained by evaporation. This process has been much altered, and, we think, amended in the present Pharmacopœia. Indeed, M. Fleurot, after trying the process, came to the conclusion that it was fallacious. (*Pharm. Journ.*, July, 1864, p. 21.) M. Fleurot has proposed a formula of his own, which appears to have served as the basis of the amended British process, especially in reference to the addition of ammonia to the solution of the oxide of iron and the quinia in the citric acid. (*Journ. de Pharm.*, 4e sér., i. 443.) The use of the two sulphates of iron has been abandoned, and only the solution of the persulphate retained. From this the freshly precipitated hydrated sesquioxide of iron is obtained by precipitation with ammonia. The next step is to separate quinia from the sulphate, by simply dissolving the salt in water with the aid of sulphuric acid, and then precipitating by ammonia. Thirdly, the sesquioxide and quinia are dissolved successively, with the heat of a water-bath, in solution of citric acid, whereby a citrate of iron and of quinia is obtained. The ammonia appears to be added in order to render the citrate of iron and quinia more soluble by the agency of a portion of citrate of ammonia. It is important that the ammonia should not be added in excess; on the contrary, the solution should retain a slight acid reaction. (*Fleurot.*) After evaporation, the salt is dried, as in the other process, on glass or porcelain, so as to be obtained in thin scales.

The U. S. and Br. preparations now essentially agree; both consisting of citric acid, sesquioxide of iron, and quinia; the British, however, containing in addition a little citrate of ammonia. The Br. preparation of 1864 consisted of citric acid, mixed sesquioxide and protoxide of iron, and quinia. No such analysis of either salt has been made as to determine precisely its equivalent composition; but the U. S. salt is probably a mixture of the proper citrate of iron and quinia with citrate of the sesquioxide.

The characters of the U. S. salt, as given in the Pharmacopœia, are the following. "In thin transparent scales, varying in colour from reddish-brown to yellowish-brown with a tint of green, according to the thickness of the scales. Its taste is ferruginous and moderately bitter. It is slowly soluble in cold water, more readily so in hot water, but insoluble in ether and officinal alcohol. Ammonia, added to the aqueous solution, deepens its colour to reddish-brown, and causes a whitish curdy precipitate of quinia; but no sesquioxide of iron is thrown down."

The British citrate is described as in thin scales of a greenish golden-yellow colour, of a bitter and chalybeate taste, somewhat deliquescent, which does not seem to be the case with the former salt, and entirely soluble in cold water. "The solution is very slightly acid, and is precipitated reddish-brown by solution of soda, white by solution of ammonia, blue by the red and yellow prussiates* of potash, and grayish-black by tannic acid." *Br.* The following additional tests are given in the Br. Pharmacopœia. "When burned with exposure to air, it leaves a residue which when moistened with water is not alkaline to test paper [oxide of iron]. Fifty grains, dissolved in a fluidounce of water, and treated with a slight excess of ammonia, give a white precipitate [quinia] which, when collected on a filter and dried, weighs 8 grains. The precipitate is almost entirely soluble in pure ether [showing the absence of cinchonia and quinidia] and when burned leaves but a minute residue." *Br.* When dissolved by the aid of an acid, it forms a solution which, decolorized by a little purified animal charcoal, turns the plane of polarization strongly to the left; a character of quinia; cinchonia turning it to the right. (*Squire.*)

The salt is said to be sometimes adulterated by cinchonia, which would be at once detected by the test of solubility in ether and the effect on polarized light, above given. As it occurs in the British market, it is of exceedingly variable composition, containing, according to Mr. J. C. Braithwaite, who examined 35 different specimens, a proportion of quinia varying from 1·5 to 17 per cent.; scarcely any two specimens being exactly alike. (*Pharm. Journ. and Trans.*, Sept. 1868, p. 157.)

Citrate of iron and quinia combines the virtues of its two bases, and may be given in all cases in which iron and quinia are jointly indicated. It is, therefore, admirably adapted to the cases of anæmia, with enlarged spleen, which are so apt to accompany and follow our autumnal fevers. It may be given in pill or solution, in the dose, as a tonic, of five or six grains, containing about a grain of quinia, three or four times a day. This dose may be greatly increased, if deemed advisable. . W.

FERRI FERROCYANIDUM. *U. S.* Ferri Ferrocyanuretum. *U.S.* 1850. *Ferrocyanide of Iron. Ferrocyanuret of Iron. Pure Prussian Blue.*

"Take of Ferrocyanide of Potassium *nine troyounces;* Solution of Tersulphate of Iron *a pint;* Water *three pints.* Dissolve the Ferrocyanide of Potassium in two pints of the Water, and add the solution gradually to the Solution of Tersulphate of Iron, previously diluted with the remainder of the Water, stirring the mixture during the addition. Then filter the liquid, and wash the precipitate on the filter with boiling water until the washings pass nearly tasteless. Lastly, dry it, and rub it into powder." *U. S.*

In the U. S. Pharmacopœia of 1850, tersulphate of sesquioxide of iron was prepared as the first step of the process; in the present formula, it is taken already prepared, in the form of the officinal solution. This salt is decomposed by the gradual addition of the solution of ferrocyanide of potassium. Three eqs. of ferrocyanide and two of tersulphate of sesquioxide of iron are mutually decomposed, with the result of forming one eq. of Prussian blue, or the 3–4 ferrocyanide of iron, which precipitates, and six eqs. of sulphate of potassa, which remain in solution. Ferrocyanogen is a tercyanide of iron ($FeCy_3$); and representing it by its symbol Cfy, we may compactly express the above reaction by the following equation: $3K_2Cfy$ and $2(Fe_2O_3,3SO_3)=Fe_4Cfy_3$ and $6(KO,SO_3)$. Prussian blue contains the elements of six eqs. of water, which cannot be separated without the destruction of the compound. Adding these elements, we may suppose it to become a hydroferrocyanate of the sesquioxide of iron, represented by the formula $2Fe_2O_3,3H_2Cfy$. From the formula given for the anhydrous com-

* Has not this test been retained by inadvertence, from the former British Pharmacopœia? It indicates the presence of both protoxide and sesquioxide of iron, which was true of the preparation of 1864, but is not so of the present, which contains only the sesquioxide.

pound (Fe_4Cfy_3), it is evident that it contains seven eqs. of iron and nine of cyanogen.

Preparation for Use in the Arts. Prussian blue is manufactured on the large scale as follows. A mixture made of equal parts of carbonate of potassa (pearl-ash of commerce) and of animal matter, such as dried blood, hair, the shavings of horn, &c., is calcined at a red heat, in an iron vessel, until it becomes pasty. The mass, when cold, is thrown, by portions at a time, into twelve or fifteen times its weight of water, with which it is stirred for half an hour. The whole is then put upon a linen filter; and the clear solution obtained is precipitated by a mixed solution of two parts of alum and one of sulphate of protoxide of iron. An effervescence occurs, due principally to carbonic acid; and a very abundant precipitate is thrown down of a blackish-brown colour. This precipitate is washed, by decantation, by means of a large quantity of water, which is removed every twelve hours. By these washings, which last from twenty to twenty-five days, the precipitate becomes successively greenish-brown, bluish, and finally deep-blue. When of the latter colour, it is collected and allowed to drain upon a cloth, after which it is divided into cubical masses and dried. In relation to the manufacture of Prussian blue, see the *Pharmaceutical Journal* (March, 1856, p. 423, and May, 1856, p. 511).*

Properties. Pure Prussian blue is a tasteless powder, insoluble in water and alcohol, and having a rich deep-blue colour. It is insoluble in dilute acids, decomposed by fuming nitric acid, and dissolved without decomposition by strong sulphuric acid, forming a white mass of the consistence of paste, from which the Prussian blue may be precipitated unchanged by water. Concentrated muriatic acid decomposes it, dissolving sesquioxide of iron, and liberating hydroferrocyanic acid (H_2Cfy). Boiled with red oxide of mercury, it generates bicyanide of mercury. (See *Hydrargyri Cyanidum.*) By the contact of a red-hot body, it takes fire and burns slowly, leaving a residue of sesquioxide of iron. When it is heated in close vessels, water, hydrocyanic acid, and carbonate of ammonia are evolved, and carburet of iron is left. Its composition has been given above. The Prussian blue of commerce was discovered by accident, in 1710, by Diesbach, a preparer of colours at Berlin. It has the same general properties as the pure substance. It occurs in small rectangular masses, which are heavier than water, and have a fracture presenting a bronzed appearance. Besides the constituents of pure Prussian blue, it always contains uncombined sesquioxide of iron, and a portion of alumina, derived from the alum employed in its manufacture, which serves to give it body as a pigment. These substances may be detected by boiling the pigment with dilute muriatic acid, and precipitating the filtered solution with ammonia. Pure Prussian blue, treated in this manner, yields no precipitate.

Medical Properties, &c. Prussian blue is deemed a tonic, febrifuge, and alterative. Dr. Zollickoffer, of Maryland, recommended it in intermittent and remittent fevers, and deemed it to be particularly adapted to the cases of children, on account of the smallness of the dose and its want of taste. He considered it more certain, prompt, and efficacious than the bark; while it has the advantage of being admissible in the state of pyrexia, and of not disagreeing with the most irritable stomach. It has also been used by Dr. Kirchoff, of Ghent, in epi-

* *Soluble Prussian Blue.* A preparation under this name has been introduced into use for injecting anatomical preparations by Schrœder Van Der Kolk, and is said to be much esteemed for this purpose. To obtain it there must be a great excess of the yellow prussiate of potassa in concentrated solution. The iron should be in the state of sesquichloride, in the proportion of not more than $\frac{1}{8}$ or $\frac{1}{10}$ of the prussiate employed. After their mixture, the precipitate is washed with water till it begins to become blue, when it is expressed and dried in the air. On the small scale it may be economically obtained in the following manner. Take solutions of the prussiate containing 217 grammes to the litre of water, and of the sesquichloride containing one part of the solid salt in 10 parts of water. Then, taking equal volumes of the two solutions, add to each one twice its volume of a cold concentrated solution of sulphate of soda, and mix the solutions. Put on a filter, and treat as directed above. The product dried in the air is perfectly soluble, and admirably adapted for injection. (*Journ. de Pharm.*, 4e sér., iv. 238.)—*Note to the thirteenth edition.*

lepsy with advantage. Dr. Bridges, of this city, exhibited it in a case of severe and protracted facial neuralgia, with considerable relief, after the usual remedies for this complaint had been tried with little or no benefit. It is sometimes employed as an application to ill-conditioned ulcers, mixed with simple ointment in the proportion of a drachm to the ounce. The dose of pure Prussian blue is from three to five grains, repeated several times a day, and gradually increased until some obvious effect is produced. B.

FERRI IODIDUM. *Br. Iodide of Iron.*

"Take of Fine Iron Wire *one ounce and a half* [avoirdupois]; Iodine *three ounces* [avoird.]; Distilled Water *fifteen fluidounces*. Put the Iodine, Iron, and twelve [fluid]ounces of the Water into a flask, and having heated the mixture gently for about ten minutes, raise the heat and boil until the froth becomes white. Pass the solution as quickly as possible through a wetted calico filter into a dish of polished iron, washing the filter with the remainder of the Water, and boil down until a drop of the solution taken out on the end of an iron wire solidifies on cooling. The liquid should now be poured out on a porcelain dish, and, as soon as it has solidified, should be broken into fragments, and enclosed in a well-stoppered bottle." *Br.*

The solid iodide of iron is omitted in the present edition of the U. S. Pharmacopœia, which directs it in the form of pills and syrup prepared immediately from the materials; the iodide itself being so liable to spontaneous change, as to render its preservation for any length of time unaltered almost impossible.

In the Br. process, which is a modification of that of the late Dublin Pharmacopœia, iron is made to unite with iodine by the intervention of water, and the combination takes place readily and quickly. The liquid at first is red or orange-coloured, from the circumstance that all the iodine has not united with the iron; but, after the application of heat, it becomes fully saturated and limpid, and assumes a greenish colour. It is now a solution of iodide of iron, and yields the solid salt by evaporation. The proportion of the iron taken is half the weight of the iodine. Fine iron wire, recently cleaned, is directed on account of its purity; but iron filings dissolve more readily, and, if carefully selected, will be sufficiently pure. It is exceedingly difficult to obtain this salt in the solid state perfectly pure, so great is the proneness of its solution to absorb oxygen, whereby the iodide becomes, in part, converted into sesquioxide. This change is prevented to a certain extent by evaporating to dryness in an *iron* vessel.

The Messrs. T. & H. Smith, of Edinburgh, recommend the following improved process, which more effectually excludes atmospheric air. Boil, in a Florence flask, six drachms of pure iron filings with two ounces and a quarter of iodine, in four and a half ounces of distilled water, until the liquid loses its dark colour. Then filter the liquid rapidly into another flask, and evaporate it, at a boiling heat, until its green shade passes into black. After this period, the heat is kept up as long as the evaporation of moisture continues, which may be ascertained by its condensation on a cold piece of glass, placed, from time to time, over the mouth of the flask. When this ceases, the flask contains pure, anhydrous, spongy iodide of iron, which, when cold, is to be removed by breaking the flask, bruised coarsely in a warm dry mortar, and enclosed immediately in small well-corked bottles. If it is wished to obtain the iodide as a crystallized hydrate, the heat is to be withdrawn as soon as the liquid is sufficiently concentrated to congeal, in a dry and hard crust, on the end of an iron wire dipped into it. A modification of this process by Dr. Squibb will be found in the *American Journal of Pharmacy* for Jan. 1859 (p. 52).

Properties. Iodide of iron is a crystalline substance, exceedingly deliquescent, of a greenish-black colour, and styptic, chalybeate taste. Its solution, by evaporation with as little contact of air as possible, affords transparent, green, tabular crystals. When heated moderately it fuses, and, on cooling, becomes an opaque crystalline mass, having an iron-gray colour and metallic lustre. At a higher temperature it emits violet-coloured vapours, and the iron is left in the state of

sesquioxide. It is very soluble both in water and alcohol. When recently prepared it is wholly soluble in water, forming a pale-green solution; but, if made for some time, it almost unavoidably contains some sesquioxide of iron, from a partial decomposition, and will not entirely dissolve. M. Lecoq, of Saint-Quentin, has proposed to preserve it in a wide-mouthed, ground-stoppered bottle, covered with a layer of reduced iron, which cannot decompose it, and protects it from the action of the air. When the iodide is wanted, the iron is removed with a bone spatula, or a little brush. The aqueous solution is very liable to spontaneous decomposition, becoming at last orange-red from the generation of free iodine, and depositing sesquioxide of iron. According to Mr. Richard Phillips, jun., the first step in this change is the formation of protoxide of iron and hydriodic acid, from the decomposition of water. As the protoxide immediately begins to be converted into sesquioxide by absorbing oxygen from the air, and in this state is precipitated, the hydriodic acid is set free; and hence is explained the acidity of the solution from the first moment the sesquioxide is deposited. Afterwards, the hydriodic acid is decomposed by the air, and iodine liberated. When the solution is prevented from generating free iodine, by placing in it a coil of iron wire, according to the plan of Mr. Squire, the iron acts by combining with the iodine of nascent hydriodic acid, and not with nascent iodine. (*Pharm. Journ.*, iv. 19.) The plan of Mr. Squire does not prevent the deposition of sesquioxide, and has, therefore, been superseded by the use of saccharine matter, which affords a better protection to the solution. (See *Syrupus Ferri Iodidi.*) Iodide of iron is incompatible with alkalies and their carbonates, with lime-water, and with all other substances by which sulphate of iron is decomposed. When crystallized it consists of one eq. of iodine 126·3, one of iron 28, and five of water 45 = 199·3. "Mixed with mucilage of starch, it acquires a blue colour on the addition of a minute quantity of solution of chlorine" (*Br.*); showing the presence of iodine, which is separated by the chlorine.*

Medical Properties and Uses. Iodide of iron was first employed in medicine by Dr. Pierquin in 1824. It was first used in the United States in 1832 by Professor Samuel Jackson, of this city, at whose request it was prepared in solution by Mr. E. Durand. Its powers are those of a tonic, alterative, diuretic, and emmenagogue. It acts more like the preparations of iron than like those of iodine. It sometimes sharpens the appetite and promotes digestion, and occasionally proves laxative. When it does not operate on the bowels, it generally augments the urine. Its use blackens the stools and lessens their fetor. It is chiefly employed in scrofulous complaints, swellings of the cervical glands, visceral obstructions attended with deficient action, chlorosis, atonic amenorrhœa, and leucorrhœa. In the two diseases last mentioned, Dr. Pierquin employed it with success. Dr. Burguet, of Bordeaux, cured a case of diabetes, of long standing, by the use of the remedy for several months. In obstinate syphilitic ulcers, M. Baumes, of Lyons, used it with satisfactory results. He gave it in the form of pill, conjoined with extract of opium, and sometimes increased the dose to 20 grains in the course of twenty-four hours. In secondary syphilis, occurring in debilitated and scrofulous subjects, Ricord has found it a valuable remedy. The dose is a grain, gradually increased to eight grains or more.

This salt, on account of its deliquescent property, and proneness to decomposition, should not be given in pill, unless protected from change by saccharine matter, or other means. (See *Pilulæ Ferri Iodidi.*) The most convenient form of exhibition is that of syrup or glycerate.†

* *Preservation of the Protiodide and Protosulphate of Iron.* A new method of accomplishing this object has been proposed by M. Carlo Pavesi of Mortara. His method consists in incorporating the salt with gum arabic in concentrated solution, evaporating with a gentle heat, and drying on porcelain plates, so as to obtain the salt in scales. These are to be kept in bottles well stopped. (*Journ. de Pharm.*, 4e sér., iii. 49.)—*Note to the thirteenth edition.*

† *Glycerate of Iodide of Iron.* Glycerin has the property at once of dissolving and preserving iodide of iron, and therefore makes an excellent excipient. M. Veza proposes the following formula. "Take of Iodine 35 parts, Iron, in powder, 70 parts, and Gly-

For forming enemata, injections for the vagina, and lotions for ulcers, one or two drachms of the iodide may be dissolved in a pint of water. B.

FERRI LACTAS. *U. S.* *Lactate of Iron.*

"Take of Lactic Acid *a fluidounce;* Iron, in the form of filings, *half a troyounce;* Distilled Water *a sufficient quantity.* Mix the Acid with a pint of Distilled Water in an iron vessel, add the Iron, and digest the mixture on a water-bath, supplying Distilled Water, from time to time, to preserve the measure. When the action has ceased, filter the solution, while hot, into a porcelain capsule, and set it aside to crystallize. At the end of forty-eight hours, decant the liquid, wash the crystals with a little alcohol, and dry them on bibulous paper. By evaporating the mother-water in an iron vessel to one-half, filtering while hot, and setting the liquid aside, more crystals may be obtained." *U. S.*

In this process the iron is protoxidized by the water, and the lactic acid unites with the protoxide, forming lactate of iron, a part of which crystallizes when the solution cools, and the remainder is obtained by evaporation and crystallization. It may be more cheaply prepared, on the large scale, by digesting the impure acid first obtained in M. Louradour's process (see *page* 49), with iron filings, or by reaction between sulphate of iron and the lactate of lime or lactate of zinc prepared as a step in obtaining lactic acid. (*Ibid.*) The following is M. Gobley's process for making lactate of lime, preparatory to its conversion into lactate of iron. Add to 2 pints of skim-milk, diluted with twice its bulk of water, and contained in an earthen pan, 64 drachms of powdered lactin, and 51 drachms of powdered chalk. Allow the whole to ferment for eleven or twelve days, at a temperature of from 80° to 90°, supplying water as it evaporates. Transfer the liquor to a capsule, heat it gradually to boiling, and stir it constantly. Boil for a quarter of an hour to coagulate casein, allow the insoluble matters to subside, and strain the liquid through flannel. The clear liquid is a solution of lactate of lime. In this process the casein of the milk, acting as a ferment, converts not only the lactin of the milk, but the lactin added, into lactic acid; a result which would not take place were it not for the presence of the chalk, which saturates the lactic acid as it is formed, and prevents it from uniting with the casein, whereby the power of the latter as a ferment would be destroyed. (*Journ. de Pharm.*, 3e sér., vi. 54.) Lactate of lime may be expeditiously converted into lactate of iron by the following process of M. Lepage. Dissolve 100 parts of lactate of lime, obtained by M. Gobley's process, in 500 parts of boiling water; and 68 parts of pure crystallized sulphate of protoxide of iron in 500 parts of cold distilled water. Mix the filtered solutions in a matrass, acidulate slightly with lactic acid, and heat in a water-bath, stirring frequently until the double decomposition is completed. Then filter to separate the sulphate of lime, and evaporate rapidly to one-half, either in an iron vessel, or in a porcelain capsule containing a few turnings of iron. Filter again, and set aside to crystallize; and, having washed the crystals in a funnel with a little alcohol, dry them on bibulous paper. (*Journ. de Pharm.*, 3e sér., ix. 272.) In relation to the precautions to be observed in preparing this lactate, so as to prevent the partial sesquioxidation of the iron, see the paper of M. C. J. Thirault in the *Journal de Pharmacie*, copied into the *Am. Journ. of Pharm.* for Nov., 1853 (p. 556).

Lactate of iron is in greenish-white crystalline crusts or grains, undergoing little change in the air. When in the form of a yellowish or greenish-white powder it is impure. It is but sparingly soluble in water, requiring 48 parts of cold and 12 of boiling water to dissolve it, and is insoluble in alcohol. It has an acid reaction, and possesses a mild, sweetish, ferruginous taste. The aqueous solution quickly becomes yellow, in consequence of the iron passing to a higher state of oxidation. M. Louradour has seen several samples of this lactate, variously

cerin 400 parts. Mix them." The colour of the solution is an emerald green; its taste is bitter and astringent; and tests do not detect in it the presence of free iodine. It may be used for preparing the syrup or pills. Five grains of it contain one of the iodide of iron. (*Journ. de Pharm.*, Oct. 1862, p. 338.)—*Note to the twelfth edition.*

adulterated; as with effloresced sulphate of iron, starch, and lactin; the sophistication being concealed by the sale of the salt in powder. These impurities may be detected by appropriate reagents; but M. Louradour recommends, as a simpler way of avoiding them, the rejection of the salt when not in crystalline crusts. "Exposed to heat it froths up, gives out thick, white, acid fumes, and becomes black; sesquioxide of iron being left. If it be boiled for fifteen minutes with nitric acid of the sp. gr. 1·20, a white granular deposit of mucic acid will occur on the cooling of the liquid." (*U. S.*) These tests indicate that it is a lactate of iron.

Medical Properties. Lactate of iron has the general medical properties of the ferruginous preparations. It has a marked effect in increasing the appetite. The disease in which it was principally tried in Paris was chlorosis, with or without amenorrhœa; and in this disease, Andral, Fouquier, Bouillaud, and others obtained very favourable results. The dose is one or two grains, repeated at intervals and gradually increased. As much as 12 or even 20 grains may be given in the course of a day. It may be administered in lozenge, pill, or syrup. The *lozenge* may be made of one grain of the lactate to twelve of sugar; and the *pill*, of one grain of the salt, with an equal weight of some inert powder free from astringent matter, and sufficient honey. The following is the formula for a *syrup* proposed by M. Cap, expressed in the nearest weights and measures used in this country. Take of lactate of iron *a drachm;* white sugar *twelve ounces and a half;* boiling distilled water *six fluidounces and a half.* Rub the salt to powder with half an ounce of the sugar; and dissolve the mixture quickly in the boiling water. Pour the solution into a matrass placed on a sand-bath, and add to it the rest of the sugar in small pieces. When the sugar is dissolved, filter the syrup, and, as soon as it is cold, transfer it to bottles which must be well stopped. This syrup has a very light amber colour, and contains about four grains of the salt to the fluidounce. The dose is from two to four fluidrachms. Bread, called *chalybeate bread*, containing lactate of iron in the proportion of about a grain to the ounce, has been used with advantage by chlorotic patients in one of the hospitals of Paris. The bread is not injured in taste or quality. Prof. Brainard, of Chicago, has treated, with success, a large erectile tumour of the orbit, by infiltrating it by injection with a fluidrachm of a solution of lactate of iron, containing eight grains of the salt. (*Ranking's Abstract*, xviii. 253.) B.

FERRI OXIDUM HYDRATUM. *U.S.* Ferri Peroxidum Humidum. *Br.* Ferrugo. *Ed.* *Hydrated Oxide of Iron. Hydrated Peroxide of Iron. Hydrated Sesquioxide of Iron. Moist Peroxide of Iron.*

"Take of Solution of Tersulphate of Iron *a pint;* Water of Ammonia, Water, each, *a sufficient quantity.* To the Solution of Tersulphate of Iron, previously mixed with three pints of Water, add Water of Ammonia, with constant stirring, until in slight excess. Then pour the whole on a wet muslin strainer, and wash the precipitate with water until the washings pass nearly tasteless. Lastly, mix the precipitate with sufficient Water to make the mixture measure a pint and a half, and transfer it to a wide-mouthed bottle, which must be well stopped.

"When Hydrated Oxide of Iron is to be made in haste for use as an antidote, the washing may be performed more quickly, though less perfectly, by pressing the strainer forcibly with the hands until no more liquid passes, and then mixing the precipitate with sufficient Water to bring the mixture to the measure of a pint and a half." *U. S.*

The British Pharmacopœia defines this preparation to be hydrated peroxide of iron with about 86 per cent. of uncombined water, and gives the following formula:

"Take of Solution of Persulphate of Iron *four fluidounces;* Solution of Soda *thirty-three fluidounces;* Distilled Water *a sufficiency.* Mix the Solution of Persulphate of Iron with a pint [Imperial measure] of the Distilled Water, and add this gradually to the Solution of Soda, stirring them constantly and briskly. Let the mixture stand for two hours, stirring it occasionally, then put it on a calico filter, and when the liquid has drained away, wash the precipitate

with Distilled Water, until what passes through the filter ceases to give a precipitate with chloride of barium. Lastly, enclose the precipitate, without drying it, in a stoppered bottle or other suitable vessel from which evaporation cannot take place. This preparation, when used, should be recently made." *Br.*

This preparation was introduced into the officinal catalogues on account of its importance as an antidote to arsenious acid. In the former processes the first step was to convert the sulphate of protoxide of iron into the tersulphate of sesquioxide; but in the present the officinal solution of tersulphate of iron (persulphate, *Br.*) is taken already containing the iron in the proper state of oxidation. This is simply treated with water of ammonia (*U. S.*), or diluted solution of soda (*Br.*), which throws down the sesquioxide combined with water, constituting the hydrated sesquioxide required. After due washing, it is mixed with water in order to maintain its pulpy state, and then carefully enclosed in bottles, which should be wide-mouthed, in order to permit its ready extraction.

Besides having this antidote ready formed in the pulpy state, it is the duty of the apothecary to be always prepared to make it, by keeping the necessary solutions for its precipitation; namely, the solution of tersulphate of sesquioxide of iron and solution of ammonia. In relation to this subject the reader is referred to a paper by Prof. Procter, in the *American Journal of Pharmacy* for March, 1853 (p. 104).

Properties. Hydrated oxide of iron, as directed to be kept by the U. S. formula, is a soft, moist, reddish-brown magma. If dried at a heat not exceeding 180°, and afterwards pulverized, it forms a reddish-brown powder, not attracted by the magnet, being the sesquioxide in the state of hydrate, containing about 18 per cent. of water. In this state it is wholly and readily soluble in muriatic acid without effervescence; and the solution gives a copious blue precipitate with the yellow but not with the red prussiate of potash. "A little of it dried at 212°, until it ceases to lose weight, gives off moisture when heated to dull redness in a test tube." *Br.* If exposed to a red heat it loses the combined water, and becomes the anhydrous sesquioxide, less easily soluble in acids, improper for medicinal use, and altogether without effect as an antidote. Hydrated oxide of iron consists of one eq. of sesquioxide 80, and two of water 18=98, and is represented by the formula Fe_2O_3+2HO. Kept for some time in the pulpy state, it loses half its combined water, and becomes less soluble in acids, and less efficient as an antidote.

Medical Properties and Uses. The hydrated oxide of iron is not an eligible ferruginous preparation for medical use. Its antidotal powers in poisoning by arsenic, the manner in which it acts, the circumstances which impair its efficiency, and the mode of using it are fully explained under arsenious acid (*page* 29). Its power of rendering arsenious acid insoluble is readily shown by agitating a solution of the acid with a considerable excess of the moist oxide, filtering, and then testing the filtered solution for the acid; not a trace of the metal can be detected, even by sulphuretted hydrogen. The hydrated oxide, as obtained by the U. S. formula, contains a little ammonia, which is thought by some to assist its antidotal powers. At least it has been ascertained that the sesquioxide, when precipitated by potassa as formerly directed by the Dublin College, is less efficient than when precipitated by ammonia, and must be employed in quantities three or four times as large to produce the same effect. The dry hydrate, rubbed up with water, is in the same proportion weaker than the pulpy hydrate. It has already been mentioned, under arsenious acid, that the officinal subcarbonate of iron (formerly called precipitated carbonate) possesses antidotal powers to arsenic, though in an inferior degree; but this statement will not apply to it, after it has been exposed to a red heat, to which it is improperly subjected by some manufacturing chemists. By ignition it becomes anhydrous, and altogether inefficient as an antidote.

Off. Prep. Ferri Peroxidum Hydratum, *Br.* B

FERRI OXIDUM MAGNETICUM. *Br.* *Magnetic Oxide of Iron. Martial Ethiops.*

"Take of Solution of Persulphate of Iron *five and a half fluidounces* [Imperial measure]; Sulphate of Iron *two ounces* [avoirdupois]; Solution of Soda *four pints* [Imp. meas.]; Distilled Water *a sufficiency*. Dissolve the Sulphate of Iron in two pints [Imp. meas.] of the Water, and add to it the Solution of Persulphate of Iron, then mix this with the Solution of Soda, stirring them well together. Boil the mixture, let it stand for two hours, stirring it occasionally, then put it on a calico filter, and when the liquid has drained away, wash the precipitate with Distilled Water, until what passes through the filter ceases to give a precipitate with chloride of barium. Lastly, dry the precipitate at a temperature not exceeding 120°." *Br.*

Though the object of this formula is the same as that of the Br. Pharmacopœia of 1864, the proceeding is different. The point aimed at is to get an oxide of iron containing one eq. of the protoxide and one of the sesquioxide (FeO,Fe_2O_3) or (Fe_3O_4, *Br.*). This was attained in the former process by converting a portion of sulphate of protoxide of iron by boiling with nitric acid into sulphate of sesquioxide, and then, having mixed this in solution with solution of the sulphate of the protoxide, precipitating the two oxides conjointly with solution of soda. In the present formula the two sulphates are taken already formed; and the process consists essentially in precipitating, as before, their joint solutions by solution of soda; the proportion of the ferruginous salts being so adjusted as to yield an eq. each of the protoxide and sesquioxide. The solution of the salts of iron is directed to be added to that of the alkali; because, if the alkaline be added to the ferruginous solution, as there would be a great excess of the salt of iron, an insoluble basic sulphate would be precipitated, and might wholly or partially escape decomposition. (Redwood, *Pharm. Journ. and Trans.*, April, 1868, p. 464.) Now such a compound oxide corresponds in composition with the native magnetic black oxide. The precipitate is washed to remove sulphate of soda, and the washings are known to be completed when the chloride of barium ceases to give a precipitate with them.

Properties, &c. The artificial magnetic oxide of iron is a brownish-black powder, without taste, and strongly magnetic. According to the Br. Pharmacopœia, it consists of a 3-4 oxide of iron, Fe_3O_4, with about 20 per cent. of water of hydration, and a portion of peroxide (sesquioxide) of iron. It dissolves without effervescence in muriatic acid diluted with half its bulk of water; and the solution gives a blue precipitate both with the ferrocyanide and ferridcyanide of potassium, showing the presence of the protoxide and sesquioxide of iron.

The Br. Pharmacopœia gives the following tests. "When a small quantity is heated in a dry test tube by the flame of a lamp, a deposit of moisture takes place on the cool part of the tube. Twenty grains dissolved in hydrochloric acid continue to give a blue precipitate with the red prussiate of potash [ferridcyanide of potassium] until 83 grain-measures of the *volumetric solution of bichromate of potash* have been added." The former test simply indicates the presence of water in the oxide; the second the quantity of protoxide present, which must be such as to require the indicated quantity of the bichromate for its sesquioxidation. The dose is from five to twenty grains, given several times a day.

Scales of iron (*ferri squamæ*) were formerly officinal with the Dublin College under the name of black oxide. They were prepared from the scales found at the blacksmith's anvil, by washing them with water, separating them from impurities by means of a magnet, and reducing them to a fine powder. They are of variable composition; being mixtures of the two oxides of iron with metallic iron. In view of their want of uniformity in composition, they were abandoned by the College for the magnetic oxide. B.

FERRI PEROXIDUM HYDRATUM. *Br.* FERRI PEROXIDUM. *Br.* 1864. *Hydrated Peroxide of Iron. Peroxide of Iron. Sesquioxide of Iron.*

"Take of Moist Peroxide of Iron *one pound* [avoirdupois]. Dry it at a tem-

perature not exceeding 212° until it ceases to lose weight, then reduce it to fine powder." *Br.*

This is the late Dublin process slightly modified. The hydrated oxide (Fe_2O_3, 2HO) loses, by the process, one-half of its combined water, and is converted into the monohydrated sesquioxide (Fe_2O_3,HO), which is the present officinal preparation. As prepared by the Dublin process, in which it was heated to redness, it lost the second eq. of water, and became the anhydrous sesquioxide (Fe_2O_3), identical with the *colcothar* of commerce.

Properties, &c. This oxide is a reddish-brown, tasteless, insoluble powder, differing from colcothar in containing an eq. of water. Hence, "heated to dull redness in a test tube it gives off moisture." *Br.* It should not be deliquescent, and should dissolve entirely in muriatic acid without effervescence. Its solution in diluted muriatic acid yields a copious blue precipitate with the ferrocyanide of potassium, but none with the ferridcyanide; showing that it contains sesquioxide of iron but no protoxide. If it contain copper, its muriatic solution will deposit this metal on a bright piece of iron. M. Dawies states that, if the hydrated oxide recently prepared be kept for four or five days in boiling water, it loses a large proportion of its water, containing at the end of that time only 5·77 per cent. The larger portion of the oxide has, therefore, become dehydrated; and the same thing happens at a lower temperature (106°) in two or three months. It becomes of a brick-red colour, and is but slightly soluble in nitric acid. (*Journ. de Pharm.*, 4e sér., iv. 400.) This oxide is not used as a medicine. It is employed in making iron plaster and reduced iron, for which purposes other forms of oxidized iron would answer as well. The former Dublin *rubigo ferri* or *rust of iron*, formed by exposing moistened iron wire to the air till converted into rust, is essentially the sesquioxide, containing a little carbonate of the protoxide.

Off. Prep. Emplastrum Ferri, *Br.*; Ferrum Redactum, *Br.* B.

FERRI PHOSPHAS. *U. S.*, *Br.* *Phosphate of Iron.*

"Take of Sulphate of Iron *five troyounces;* Phosphate of Soda *six troyounces;* Water *eight pints.* Dissolve the Salts separately, each in four pints of the Water; then mix the solutions, and set the mixture by that the precipitate may subside. Lastly, having poured off the supernatant liquid, wash the precipitate with hot water, and dry it with a gentle heat." *U. S.*

"Take of Sulphate of Iron *three ounces* [avoirdupois]; Phosphate of Soda *two ounces and a half* [avoird.]; Acetate of Soda *one ounce* [avoird.]; Boiling Distilled Water *four pints* [Imperial measure]. Dissolve the Sulphate of Iron in one-half the Water, and the Phosphate and Acetate of Soda in the remaining half. Mix the two solutions, and, after careful stirring, transfer the precipitate to a calico filter, and wash it with hot distilled water, till the filtrate ceases to give a precipitate with chloride of barium. Finally dry the precipitate at a temperature not exceeding 120°." *Br.*

The U. S. preparation is the result of a double decomposition between the saline materials employed. As the medicinal phosphate of soda is the middle tribasic phosphate, having the composition $2NaO,HO,PO_5$, it follows that it requires two eqs. of sulphate of protoxide of iron for its decomposition, as shown by the following equation: $2(FeO,SO_3)$ and $2NaO,HO,PO_5$,$=2FeO,HO,PO_5$ and $2(NaO,SO_3)$. The resulting salts, therefore, are one eq. of the middle tribasic phosphate of iron, the salt under notice, and two eqs. of sulphate of soda, which are washed away. If the ferruginous sulphate be a perfect sulphate of the protoxide, the precipitate as first thrown down will be white; but it quickly absorbs oxygen and becomes bluish-white. When perfect it consists of two eqs. of protoxide of iron, one of basic water, and one of phosphoric acid; but generally it contains some phosphate of the sesquioxide without basic water (Fe_2O_3,PO_5).

The British phosphate of iron is a different salt; for, while the former has two eqs. of oxide of iron, this has three to one of the acid; the third being supplied by means of the acetate of soda used in the process. Supposing the double decomposition to have occurred, as in the U. S. process, between two eqs. of the

sulphate of iron and one of the double-based phosphate of soda, producing two eqs. of sulphate of soda and one of the double-based phosphate of iron; the reaction next takes place between the generated eq. of phosphate of iron, one eq. of sulphate of iron, and one of acetate of soda, resulting in the production of an additional eq. of sulphate of soda, an eq. of free acetic acid, and the addition of a third eq. of oxide of iron to the phosphate, which, being insoluble, is precipitated. This latter result arises from the strong disposition of the tribasic phosphoric acid to combine with three bases, which could only be satisfied by the liberation of an eq. of the acetic acid of the acetate. This salt, when first formed, is represented by the formula $3FeO,PO_5$; but the strong affinity of its protoxide for oxygen causes the gradual production of sesquioxide, which, therefore, to a certain extent always exists in the preparation.

Phosphate of iron, by whichever process procured, is in the form of a powder of a bright slate colour, insoluble in water, but soluble in acids. The solution in dilute muriatic acid gives a blue precipitate with both ferridcyanide and ferrocyanide of potassium, but much the more copiously with the former, proving the presence both of protoxide and sesquioxide of iron, but a great preponderance of the protoxide. With ammonia the same solution yields a precipitate insoluble in an excess of the alkali. This is a test of the U. S. Pharmacopœia, probably intended to show that the salt, while containing a portion of phosphate of sesquioxide of iron, has been quite freed by washing from phosphate of soda; for, though a precipitate is produced by ammonia with the phosphate of the protoxide, it is redissolved by an excess of the precipitant, whereas, with the sesquioxide salt, the precipitate is not redissolved by such excess, unless by the aid of phosphate of soda or other salt of similar powers. If the preparation contain arsenic, it will be detected by producing a dark precipitate on the surface of a slip of pure copper introduced into the solution.

Phosphate of iron, dissolved to saturation in a boiling solution of metaphosphoric acid (HO,PO_5), under the name of *superphosphate of iron*, was proposed as a new remedy, in Jan. 1851, by Dr. Routh, of London. Mr. Thomas Greenish, of the same city, states that the solution of the salt, on cooling, hardens into a mass of pilular consistence, soluble in water in all proportions, and free from any disagreeable or inky taste. He has prepared from it a syrup, containing five grains of the salt to the fluidrachm.

Medical Properties. Phosphate of iron possesses the general properties of the ferruginous preparations, and has been given with advantage in amenorrhœa and some forms of dyspepsia. It was introduced into the U. S. Pharmacopœia at the suggestion of the late Dr. Hewson, of this city, who found it, after an extensive experience, to be a valuable chalybeate. The dose is from five to ten grains.* B.

* *Compound Syrup of Phosphate of Iron. Chemical Food.* For a formula for a compound syrup of phosphate of iron by Mr. Wiegand, made by introducing into it the phosphates of lime, potassa, and soda, and for remarks on the pharmacy of the phosphates by Prof. Procter, see the *Am. Journ. of Pharm.* for March, 1854 (pp. 111 and 112). A formula similar to Mr. Wiegand's, communicated by Mr. Edward Parrish, as probably representing the process for a secret preparation considerably used in this city, may be found in the *Am. Journ. of Pharm.* for Nov. 1857 (p. 573). These formulas are too complicated to have any therapeutic value. Nevertheless, as the preparations have had much vogue, under the name of *chemical food*, we give the formula of Mr. Parrish from the journal referred to. "Take of Protosulphate of Iron ℥x; Phosphate of Soda ℥xii; Phosphate of Lime ℥xii; Glacial Phosphoric Acid ℥xx; Carbonate of Soda ℈ij; Carbonate of Potassa ℥i; Muriatic Acid, Water of Ammonia, each, q. s.; Powdered Cochineal ʒij; Water q. s. to make f℥xx; Sugar lbiij (troy); Oil of Orange ♏x. Dissolve the Sulphate of Iron in f℥ij, and the Phosphate of Soda in f℥iv of boiling Water. Mix the solutions, and wash the precipitated phosphate of iron till the washings are tasteless. Dissolve the Phosphate of Lime in f℥iv of boiling Water with sufficient Muriatic Acid to make a clear solution, precipitate it with Water of Ammonia, and wash the precipitate. To the freshly precipitated phosphates add the Phosphoric Acid previously dissolved in Water. When clear add the Carbonates of Soda and Potassa, and afterwards sufficient Muriatic Acid to dissolve the precipitate. Now add Cochineal mixed with the Sugar, apply heat, and when the syrup is formed, strain and flavour it. Each teaspoonful contains about ol.

FERRI PYROPHOSPHAS. *U. S. Pyrophosphate of Iron.*

"Take of Phosphate of Soda *seven troyounces and a half;* Solution of Tersulphate of Iron *seven fluidounces,* or *a sufficient quantity;* Citric Acid *two troyounces;* Water of Ammonia *five fluidounces and a half,* or *a sufficient quantity;* Water *a sufficient quantity.* Heat the Phosphate of Soda, in a porcelain capsule, until it undergoes the watery fusion, and continue the heat until it becomes dry. Transfer the dry salt to a shallow iron capsule, and heat it to incipient redness, without fusion. Then dissolve it in three pints of Water, with the aid of heat, and, having filtered the solution and cooled it to the temperature of 50°, add Solution of Tersulphate of Iron until this ceases to produce a precipitate. Stir the mixture thoroughly, and pour it upon a muslin strainer, and, when the precipitate has drained, wash it with water until the washings pass nearly tasteless, and transfer it to a weighed porcelain capsule.

"To the Citric Acid, contained in a suitable vessel, add Water of Ammonia until the Acid is saturated and dissolved. Then add the solution to the precipitate in the weighed capsule, stir them together, and evaporate until the liquid is reduced to sixteen troyounces. Spread this on plates of glass or porcelain, so that, on drying, the salt may be obtained in scales. Lastly, preserve it in a well-stopped bottle, protected from the light." *U. S.*

This formula appears to be based upon a method, proposed by M. E. Robiquet to the Academy of Medicine at Paris, in Feb. 1857, of preparing pyrophosphate of iron for use, by dissolving a gelatinous precipitate of the salt in a solution of citrate of ammonia, and forming a syrup with the solution. Prof. Procter devised a formula upon this plan, published in the *Am. Journ. of Pharm.* (Nov. 1857, p. 573), the result of which also was a syrup. The officinal formula, which provides for the preparation of the salt in the solid form, capable of being readily made into a syrup if desired, is that of Dr. Squibb published in the same journal (Jan. 1860, p. 37).

The first step in the officinal process is to convert the common tribasic phosphate of soda ($2NaO,HO,PO_5+24HO$), by moderately igniting it, into the pyrophosphate or bibasic phosphate of soda ($2NaO,PO_5$), which may be obtained crystallized by dissolving it in boiling water and evaporating, in which state it is represented by the formula $2NaO,PO_5+10HO$. The uncrystallized pyrophosphate is dissolved and mixed with solution of tersulphate of iron, when the pyrophosphate of sesquioxide of iron is deposited. This, while in a pulpy state, is added to a solution of citrate of ammonia formed by a direct union of its constituents, by which it is dissolved. The process is completed by evaporating the solution sufficiently, and then spreading it out to dry on glass or porcelain so that the salt may be obtained in scales. The reactions which result in the formation of the ferruginous salt, contained in this compound, probably take place between three eqs. of the bibasic phosphate of soda $3(2NaO,PO_5)$ and two eqs. of the tersulphate of iron $2(Fe_2O_3,3SO_3)$, forming six eqs. of sulphate of soda, and one eq. of sesquiphosphate of sesquioxide of iron, having (according to Gmelin) the equivalent composition represented by the formula $2Fe_2O_3,3PO_5+9HO$.

grain of phosphate of iron and two and a half grains of phosphate of lime, with smaller quantities of the alkaline phosphates, all in perfect solution." The objection to such preparations as this is not that each of the ingredients may not be useful; but that they are so numerous that a morbid state of system must be extremely rare in which they can all be indicated, and every medicine is more or less noxious if given when it is not needed. The probability is that the therapeutic value of the preparation depends mainly on its ferruginous ingredient, and that, as a general rule, its therapeutic effects may be equally as well, if not better obtained, from a simple syrup of phosphate of iron.

Simple Syrup of Phosphate of Iron. Subsequently, Mr. Wiegand gave a formula for a simple syrup of phosphate of iron, made by dissolving the recently precipitated salt in muriatic acid, and adding the requisite quantity of sugar. By a misprint the phosphate of soda taken is double what it should be. The same writer has proposed to make a syrup of the phosphates of iron and lime, by dissolving in the above a definite quantity of recently precipitated phosphate of lime, made by double decomposition between solutions of chloride of calcium and phosphate of soda. See his formulas in the *Am. Journ. of Pharm.* for March, 1855 (p. 104).—*Notes to the tenth, eleventh, and twelfth editions*

The preparation is probably an intimate mixture of the ferruginous and ammoniacal salts in the solid form; at least such must be the view of the revisers of the Pharmacopœia, who name it pyrophosphate of iron. It is in scales of an apple-green colour, and an acidulous somewhat saline taste. It is wholly and freely dissolved by water. Ferrocyanide of potassium occasions no precipitate with its solution, though it causes a pale-blue colour, showing that the iron is in the state of sesquioxide, and that there is a substance present (citrate of ammonia) capable of holding ferrocyanide of iron in solution. The salt contains 48 per cent. of anhydrous pyrophosphate of iron. (*U. S.*) It is a very good chalybeate, mild yet efficient in its action on the system, without disagreeable taste, and, from its solubility, readily administered in any form that may be desirable, whether that of pill, simple solution in water, or syrup. The dose is from two to five grains. A syrup may be readily prepared by dissolving it in water, and mixing the solution with simple syrup.*

Mr. S. P. Duffield, of Detroit, has failed in obtaining, by the U. S. process, a product capable of being satisfactorily dried in the form of scales, and proposes a modification consisting in digesting the magma of pyrophosphate of iron obtained in the first part of the process with water of ammonia, and then gradually adding solution of citric acid till a solution is effected. If evaporated to the consistence of syrup and spread in thin layers on glass, the product may be obtained in scales. But as the resulting salt does not, according to Mr. Duffield, contain the pyrophosphate of iron at all, but consists of a mixture of citrate of sesquioxide of iron and pyrophosphate of ammonia, however excellent the preparation may be, it cannot properly be considered as the substance officinally aimed at, the main ingredient of which is pyrophosphate of iron. (For the details of Mr. Duffield's process, see *Am. Journ. of Pharm.*, Jan. 1869, p. 58.) Mr. R. W. Gardner, of Bergen, N. J., found, in his first trials, the same difficulty in obtaining the salt in scales; but, having ascertained that he used nitric acid of less than the officinal strength in preparing the solution of tersulphate of iron employed in the formula, and consequently obtained the salt not completely sesquioxidized, and having corrected this error, he afterwards ex-

* This ferruginous pyrophosphate is soluble in pyrophosphate of soda; and hence, if an excess of pyrophosphate of soda is used in the double decomposition, the ferruginous pyrophosphate, first thrown down, is redissolved. This solution was proposed as a medicine by M. Persoz in 1848, and by M. Leras in 1849. M. Leras conceives that pyrophosphate of iron, rendered soluble by pyrophosphate of soda, is the only ferruginous preparation which is not precipitated in the stomach by the agency of the food or gastric juice. Mr. Alex. Ure, of London, tried this solution, calling it *soda-pyrophosphate of iron*, in scrofula, and found it a mild and efficient chalybeate. The same solution, as prepared by M. Leras, has been employed with marked success in anemic diseases, by MM. Follet and Baume, who found it easily administered and rapidly absorbed. In the preparation used by him, the sulphate of soda, resulting from the double decomposition, was allowed to remain. The same solution, including the sulphate of soda, has been prepared as a syrup by M. Soubeiran.

Syrup of Pyrophosphate of Iron. M. Soubeiran's formula is as follows. Add 55 *grains* of tersulphate of sesquioxide of iron, dissolved by a gentle heat in two *fluidounces* of water, to 462 grains of crystallized pyrophosphate of soda, dissolved in 7½ *fluidounces* of water and 3½ *fluidounces* of mint water, and mix. So soon as the precipitate formed redissolves, filter the solution, and add to the filtrate 19 *troyounces* of white sugar, which must be allowed to dissolve without heat. The dose of this syrup, which is easy to take, is a tablespoonful, containing about a third of a grain of iron.

An equivalent preparation may be made from the U. S. pyrophosphate of iron by dissolving 2·6 grains in a fluidounce of syrup; but this would be a feeble preparation; and, besides, the quantity of sugar might be embarrassing to the stomach. A better plan would probably be to dissolve 20 grains in a fluidounce of syrup, giving 2·5 grains of the salt to each fluidrachm, and making the dose from one to two teaspoonfuls. The salt may be dissolved in a little water before being incorporated with the syrup, care being taken that the resulting liquid should contain 20 grains to the fluidounce.

Dr. Squibb prepares a syrup of the pyrophosphate by adding to 24 parts of the solution of the formula, after filtration, 248 parts of Syrup, and thus obtains a preparation containing about two grains of the officinal salt, or one grain of the anhydrous pyrophosphate in a fluidrachm. (*Notes to the eleventh and twelfth editions.*)

perienced no difficulty, and believes that the U. S. process, if proper attention be given to its details, will always yield satisfactory results. (*Ibid.*, May, 1869.)
W.

FERRI SUBCARBONAS. *U. S. Subcarbonate of Iron. Sesquioxide of Iron. Red Oxide of Iron. Precipitated Carbonate of Iron. Aperitive Saffron of Mars.*

"Take of Sulphate of Iron *eight troyounces;* Carbonate of Soda *nine troyounces;* Water *eight pints.* Dissolve the salts separately, each in four pints of the Water; then mix the solutions, and, having stirred the mixture, set it by that the precipitate may subside. Having poured off the supernatant liquid, wash the precipitate with water until the washings pass nearly tasteless, and dry it on bibulous paper without heat." *U. S.*

When the solutions of carbonate of soda and sulphate of iron are mixed together, a hydrated carbonate of protoxide of iron, of a pale-blue colour,* is thrown down, and sulphate of soda remains in solution. The equivalent quantities of the *crystallized salts* for mutual decomposition are 139 of the sulphate and 143·3 of the carbonate. Taking the quantity of sulphate of iron at 8 parts, the U. S. Pharmacopœia orders 9 parts of the carbonate of soda, which gives a slight excess of the latter. The precipitate, during the washing and drying, absorbs oxygen, and loses nearly all its carbonic acid, whereby it is converted almost entirely into sesquioxide of iron. Hence, the London College gave it the name of *Ferri Sesquioxidum;* but, as this is applicable to the red oxide, obtained by calcining the sulphate, or igniting the hydrated sesquioxide, the U. S. name of *Ferri Subcarbonas*, adopted in allusion to the small quantity of carbonic acid present in it, is more distinctive. Carbonate of soda is preferred to carbonate of potassa for decomposing the ferruginous sulphate; because it produces in the double decomposition sulphate of soda, which, from its greater solubility, is more readily washed away than sulphate of potassa. The direction to dry the precipitate without heat is important; as even a moderate elevation of temperature has been shown, by the experiments of Mr. J. A. Rex, to modify the resulting product unfavourably, diminishing its solubility in muriatic acid in proportion to the heat employed. (*Am. Journ. of Pharm.*, May, 1862, p. 193.)

Properties. Subcarbonate of iron is a reddish-brown powder, of a disagreeable, slightly styptic taste; insoluble in water, and not readily dissolved by any acid except the muriatic, with which it effervesces slightly. When of a bright-red colour it should be rejected, as this colour shows that it has been injured by exposure to heat. After precipitation from its muriatic solution by ammonia or potassa, either of which throws down the sesquioxide of iron, the supernatant liquor should give no indications of containing any metal in solution by the test of sulphuretted hydrogen or ferrocyanide of potassium. It is incompatible with acids and acidulous salts. In composition it is a hydrated sesquioxide of iron, containing a little carbonate of the protoxide. By exposure to a red heat, it absorbs oxygen, and loses water and carbonic acid, being converted into the *astringent saffron of Mars* of the French Codex. After ignition it is no longer a subcarbonate, but is converted into the pure sesquioxide, which is less soluble in acids, and less efficient as a medicine than the preparation in its original state. Hence it is wrong to expose the subcarbonate to a red heat, as some manufacturing chemists are in the habit of doing, in order to give it a bright-red colour.

Medical Properties and Uses. Subcarbonate of iron is tonic, alterative, and emmenagogue, and is employed for all the purposes to which the preparations of iron are generally applicable. It was recommended by Mr. Carmichael in cancer, and is said sometimes to prove useful. Mr. Hutchinson brought it into notice as a remedy for neuralgia; and an extensive experience with it in that disease has established its value. It is also useful in chorea, chlorosis, and, gene-

* The carbonate of the protoxide of iron is white if perfectly pure; but as the sulphate of iron used is not absolutely pure, containing almost always a little sesquioxide, this is thrown down with the carbonate, giving it a bluish tinge.

rally, in those diseases in which the blood is deficient in red corpuscles. It has been used by Dr. Woollam, Dr. Shearman, Dr. Elliotson, and others in traumatic tetanus, with success in twelve cases, and failure in three. In the second stage of hooping-cough, Dr. Steymann represents it to be a prompt and efficacious remedy. When prescribed as a tonic, the usual dose is from five to thirty grains three times a day, given in pill or powder, and frequently combined with aromatics and vegetable tonics. In neuralgia, chorea, and tetanus, it is administered in doses of from one to two teaspoonfuls. No nicety need be observed in the dose; as its only obvious effect in very large doses is a slight nausea, and a sense of weight at the stomach. It blackens the stools.

The subcarbonate of iron acts as an antidote to the poison of arsenious acid, provided it has not been exposed to a red heat; and, though not so powerful as the hydrated oxide in the form of magma, should always be used until the latter can be procured. (See *pages* 29, 30.)

Off. Prep. Emplastrum Ferri, *U. S.;* Ferrum Redactum, *U. S.;* Trochisci Ferri Subcarbonatis, *U. S.* B.

FERRI SULPHAS. *U.S., Br. Sulphate of Iron. Green Vitriol.*

"Take of Iron, in the form of wire, and cut in pieces, *twelve troyounces;* Sulphuric acid *eighteen troyounces;* Water *eight pints.* Mix the Sulphuric Acid and Water, and add the Iron; then heat the mixture until effervescence ceases. Pour off the Solution, and, having added thirty grains of Sulphuric Acid, filter through paper, allowing the lower end of the funnel to touch the bottom of the receiving vessel. Evaporate the filtered liquor in a matrass until sufficiently concentrated; then set it aside in a covered vessel to crystallize. Drain the crystals in a funnel, dry them on bibulous paper, and keep them in a well-stopped bottle." *U. S.*

"Take of Iron Wire *four ounces* [avoirdupois]; Sulphuric Acid *four fluidounces* [Imperial measure]; Distilled Water *one pint and a half* [Imp. meas.]. Pour the Water on the Iron placed in a porcelain dish, add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filtering paper placed on porous bricks, and preserved in a stoppered bottle." *Br.*

The object of these processes is to make a pure sulphate of protoxide of iron by direct combination. Sulphuric acid, in a concentrated state, acts but imperfectly on iron; but when diluted, a vigorous action takes place, the oxygen of the water converts the metal into protoxide, with which the sulphuric acid unites, and hydrogen is evolved. The equivalent quantities for mutual reaction are 28 of iron to 49 of acid. This proportion is one part of iron to one and three-quarters of acid. The *U. S.* proportion is one part of iron to one and a half of acid, and gives a quantity of iron one-sixth more than the acid can dissolve. The *British Council* uses an excess of acid, the weight of acid taken being 7·38 avoirdupois ounces, instead of 7. An excess of iron, however, is desirable; as it tends to secure the production of a perfect sulphate of the protoxide. The remaining steps of the U. S. process are peculiar, and are intended to secure the formation of a salt, entirely free from sesquioxide, by the method of Bonsdorff. This chemist found that, when a perfect sulphate of protoxide of iron was formed in solution by heating dilute sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid were added to the liquid before filtration, in order to hold in solution any sesquioxide that may have been formed; at the same time avoiding, as much as possible, the contact of the air. Hence the directions in the U. S. formula to acidulate with sulphuric acid, to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air, and to cover the vessel containing the concentrated liquid, when it is set aside to crystallize. The *London* and *Edinburgh Colleges* prepared this officinal by purifying the impure commercial sulphate; but their plan was superseded by that of the *Dublin College* in the consolidation of the several pharmacopœias in the British.

Properties. Sulphate of iron is in the form of transparent crystals, efflorescent in the air, of a pale bluish-green colour, and having the shape of oblique rhombic prisms. It has a styptic taste, and an acid reaction. As prepared by Bonsdorff's method, it is blue verging to green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. By exposure to the air the crystals absorb oxygen, and become first green, and ultimately covered with a yellow efflorescence of monosulphate of the sesquioxide, insoluble in water. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. Sulphate of iron is soluble in about twice its weight of cold water and in three-fourths of its weight of boiling water, but is insoluble in alcohol. The aqueous solution is bluish-green; but by standing it attracts oxygen, and becomes first green and then reddish, depositing, in the mean time, a portion of sesquisulphate of the sesquioxide, having the composition $2Fe_2O_3,3SO_3+8HO$. (Wittstein, *Chemical Gazette*, May 15, 1849; from *Buchner's Repert.*) When heated moderately, it parts with six-sevenths of its water of crystallization, and becomes grayish-white. (See *Ferri Sulphas Exsiccata.*) At a red heat it loses its acid, and is converted into the anhydrous sesquioxide of iron called *colcothar*. It is incompatible with the alkalies and their carbonates, soaps, lime-water, the chlorides of calcium and barium, the borate and phosphate of soda, nitrate of silver, and the acetate and subacetate of lead. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesquioxide be present, a black compound of the nature of ink. The extent to which this change lessens the activity of the salt is not well ascertained. Sulphate of iron, as kept in the shops, is often the impure commercial sulphate, which is not fit for medicinal use.* The perfectly pure salt is precipitated white by ferrocyanide of potassium; but that of ordinary purity gives a greenish precipitate, more or less deep, with this test, owing to the presence of some sesquioxide of iron. Copper may be detected by immersing in the solution a bright piece of iron, on which a cupreous film will be deposited. Both copper and zinc may be discovered by sesquioxidizing the iron by boiling the solution of the salt with nitric acid, and then precipitating the iron by an excess of ammonia. If the filtered solution is blue, copper is present; and if it contain zinc, this will be separated in flakes of white oxide, on expelling the excess of ammonia by ebullition. Sulphate of iron, when crystallized, consists of one eq. of acid 40, one of protoxide 36, and seven of water 63=139, and its formula is FeO,SO_3+7HO.

It is often desirable to protect the sulphate of iron against the oxidation to which it is liable on exposure. Sugar acts as a preservative in the case of this

* *Commercial Sulphate of Iron.* FERRI SULPHAS VENALIS. *Lond. Green Vitriol. Copperas.* This was formerly officinal in the London Pharmacopœia, in which it was employed for preparing the pure sulphate. It is manufactured on a large scale for the purposes of the arts, from the native sulphuret of iron, or iron pyrites, by roasting, oxidation by exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and protoxide of iron, which, by their union, form the salt. Sulphate of iron is also obtained in many chemical processes as a collateral product, as in the manufacture of alum, in the precipitation of copper from solutions of sulphate of copper by scraps of iron, &c.

Commercial sulphate of iron is far from being pure. Besides containing some sesquioxide of iron, it is generally contaminated with metallic and earthy salts; such as those of copper, zinc, alumina, and magnesia. Two principal kinds occur in the market; one in large grass-green crystals, the surface of which is studded with ochreous spots; the other, of a bluish-green colour, and ordinarily mixed with the powder of the effloresced salt. The commercial sulphate should never be dispensed by the apothecary, until it has undergone a careful purification. The following was the formula of the London College for effecting this object.

"Take of Commercial Sulphate of Iron *four ounces* [*troy*]; Sulphuric Acid *a fluidounce* [Imperial measure]; Iron wire *an ounce* [*troy*]; Distilled Water *four pints* [Imp. meas.]. Mix the Acid with the Water, and add to them the Sulphate and Iron, then apply heat, stirring occasionally, till the Sulphate is dissolved. Filter the solution while hot, and set aside to crystallize. Pour off the liquor, and evaporate it that crystals may again form. Dry all the crystals." (*Note to the twelfth edition.*)

salt, as in that of protiodide of iron. It may be added to the solution, or incorporated with the sulphate in substance. M. E. Latour has given a formula for crystallizing the salt with sugar. Mr. Geo. Welborn has found a small lump of camphor, wrapped in tissue paper, and placed in the bottle with the sulphate, to prevent its oxidation. (*Pharm. Journ. and Trans.*, May, 1868, p. 537.) M. Pavesi, of Mortara, effects the same object by incorporating it with an equal weight of gum arabic, by evaporating a joint solution of the two substances with a gentle heat. (*Journ. de Pharm.*, 4e sér., iii. 49.)

Medical Properties and Uses. Sulphate of iron is astringent and tonic. In large doses it is apt to produce nausea, vomiting, griping, and purging; and its use, when long continued, injures the stomach. As its effect is chiefly that of an astringent, it cannot be used with advantage to improve the quality of the blood. As an astringent it is given in diseases attended with immoderate discharges; such as passive hemorrhages, colliquative sweats, diabetes, chronic mucous catarrh, leucorrhœa, gleet, &c. As a tonic it is used in dyspepsia, and in the debility following protracted diseases. In amenorrhœa with deficient action it is resorted to with supposed advantage, either alone or conjoined with the fetid and stimulant gums. Externally, the solution is used in chronic ophthalmia, leucorrhœa, and gleet, made of various strengths, from one or two, to eight or ten grains of the salt to the fluidounce of water. M. Velpeau has found it an excellent remedy in erysipelas, applied topically in the form of solution or ointment. In forty cases in which it was tried, it cut short the disease in from 24 to 48 hours. The solution was made of three and a half drachms of the salt to a pint of water, and applied by compresses, kept constantly wet. In a few cases convenience required the application of the ointment, made of eight parts of the salt to thirty of lard. An ointment, made of one or two parts of the sulphate to sixty of lard, was found by M. Devergie to be particularly efficacious in certain skin diseases, especially in the different forms of eczema. In scaly affections it had no effect. The dose is one or two grains, in the form of pill, which should be made from the dried sulphate. (See *Ferri Sulphas Exsiccata.*) When given in solution, the water should be previously boiled to expel the air, which, if allowed to remain, would partially decompose the salt. Taken in an over dose it acts as a poison.

The sulphate of iron has disinfecting properties, and in France is largely used in solution for the disinfection of the fecal matters of animals, manures, slaughter-houses, ditches, and all places giving rise to noxious emanations. It is mixed with the infectious matters, and applied by washing to the surface of all infected places. (*Chem. News*, April 20, 1866, p. 190.) We understand that it is also used for similar purposes in this country. Mixed with hydrated lime, and sprinkled on privy walls, it rapidly corrects the fetid emanations; the protoxide of iron and excess of lime neutralizing the sulphurretted hydrogen.

FERRI SULPHAS EXSICCATA. *U. S., Br. Dried Sulphate of Iron.*

"Take of Sulphate of Iron, in coarse powder, *twelve troyounces*. Expose it, in an unglazed earthen vessel, to a moderate heat, with occasional stirring, until it has effloresced; then increase the heat to 300°, and maintain it at about that temperature until the salt ceases to lose weight. Lastly, reduce the residue to fine powder, and keep it in a well-stopped bottle." *U. S.*

"Take of Sulphate of Iron *four ounces*. Expose it in a porcelain or iron dish to a heat commencing at 212°, but which may be finally raised to 400°, until aqueous vapour ceases to be given off. Reduce the residue to a fine powder, and preserve it in a stoppered bottle." *Br.*

In these processes six eqs. out of seven of the water of crystallization of the salt are driven off. The heat should not exceed 400°, otherwise the salt itself

would suffer decomposition. Dried sulphate of iron is used for making pills, the crystallized sulphate not being adapted to that purpose. In prescribing the dried sulphate it is necessary to recollect that three grains are equivalent to five of the crystallized salt. B.

FERRI SULPHAS GRANULATA. *Br.* *Granulated Sulphate of Iron.*

"Take of Iron Wire *four ounces* [avoirdupois]; Sulphuric Acid *four fluidounces* [Imperial measure]; Distilled Water *one pint and a half* [Imp. meas.]; Rectified Spirit *eight fluidounces* [Imp. meas.]. Pour the Water on the Iron placed in a porcelain capsule, add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes, and then filter the solution into a jar containing the spirit, stirring the mixture so that the salt shall separate in minute granular crystals. Let these, deprived by decantation of adhering liquid, be transferred on filtering paper to porous tiles, and dried by exposure to the atmosphere. They should be preserved in a stoppered bottle." *Br.*

The directions given in the first part of this process are precisely the same as those laid down by the British Council for making Sulphate of Iron; but the hot solution of the iron in the sulphuric acid, instead of being allowed to filter into an empty vessel, is made to drop into a portion of rectified spirit, the mixture being stirred while it cools. The acid directed is in excess; and the filtrate is consequently an acid solution of sulphate of protoxide of iron, mixed with spirit. The stirring as the mixture cools finely granulates the salt, which separates perfectly pure; the spirit holding in solution any tersulphate of sesquioxide of iron which may have been formed, and the excess of acid dissolving any free sesquioxide. This process, in its main features, is the same as that of M. Berthemot, given in the eighth edition of this work. It was adopted from the Dublin Pharmacopœia.

Properties, &c. Granulated sulphate of iron is a crystalline, granular, bluish-white powder. When carefully dried it undergoes no change by keeping. It appears to have been introduced into the catalogue of the Dublin Pharmacopœia of 1850, as the best form of the sulphate for conversion into the officinal dried salt; and its peculiar state of aggregation would seem to fit it for that purpose; yet this intention, if it existed, seems to have been overlooked in the revision of the British Pharmacopœia, in which the granulated salt is not directed in the formula for the dried sulphate. The only reason for its retention was probably that it is less liable to oxidation on exposure than the sulphate in its ordinary form.

Off. Prep. Syrupus Ferri Phosphatis, *Br.* B.

FERRUM REDACTUM. *U. S.*, *Br.* Ferri Pulvis. *U. S.* 1850. *Reduced Iron. Powder of Iron.*

"Take of Subcarbonate of Iron *thirty troyounces.* Wash the Subcarbonate thoroughly with water until no traces of sulphate of soda are indicated by the appropriate tests, and calcine it in a shallow vessel until free from moisture. Then spread it upon a tray, made by bending an oblong piece of sheet-iron in the form of an incomplete cylinder, and introduce this into a wrought-iron reduction-tube, of about four inches in diameter. Place the reduction-tube in a charcoal furnace; and, by means of a self-regulating generator of hydrogen, pass through it a stream of that gas, previously purified by bubbling successively through solution of subacetate of lead, diluted with three times its volume of water, and through milk of lime, severally contained in four-pint bottles, about one-third filled. Connect with the further extremity of the reduction-tube, a lead tube bent so as to dip into water. Make all the junctions air-tight by appropriate lutes; and, when the hydrogen has passed long enough to fill the whole of the apparatus to the exclusion of atmospheric air, light the fire, and bring that part of the reduction-tube, occupied by the Subcarbonate, to a dull-red heat, which must be kept up so long as the bubbles of hydrogen, breaking

from the water covering the orifice of the lead tube, are accompanied by visible aqueous vapour. When the reduction is completed, remove the fire, and allow the whole to cool to the ordinary temperature, keeping up, during the refrigeration, a moderate current of hydrogen through the apparatus. Withdraw the product from the reduction-tube, and, should any portion of it be black instead of iron-gray, separate such portion for use in a subsequent operation. Lastly, having powdered the Reduced Iron, keep it in a well-stopped bottle. When thirty troyounces of Subcarbonate of Iron are operated on, the process occupies from five to eight hours." *U. S.*

"Take of Hydrated Peroxide of Iron *one ounce* [avoirdupois]; Zinc, granulated, Sulphuric Acid, Chloride of Calcium, each, *a sufficiency*. Introduce the Hydrated Peroxide of Iron into a gun-barrel, confining it to the middle part of the tube by plugs of asbestos. Pass the gun-barrel through a furnace, and when it has been raised to a strong red heat, cause it to be traversed by a stream of hydrogen gas, developed by the action on the Zinc of some of the Sulphuric Acid diluted with eight times its volume of water. The gas before entering the gun-barrel must be rendered quite dry by being made to pass first through the remainder of the Sulphuric Acid, and then through a tube eighteen inches long, packed with small fragments of the Chloride of Calcium. The farther end of the gun-barrel is to be connected by a cork with a bent tube dipping under water; and when the hydrogen is observed to pass through the water at the same rate that it bubbles through the Sulphuric Acid, the furnace is to be allowed to cool down to the temperature of the atmosphere, the current of hydrogen being still continued. The reduced iron is then to be withdrawn, and enclosed in a dry stoppered bottle." *Br.*

This preparation was introduced into the U. S. and Dublin Pharmacopœias of 1850, and is retained in the present edition of our own, and in the British. It consists of metallic iron in fine powder, obtained by reducing the sesquioxide by hydrogen at a dull-red heat. The subcarbonate of the U. S. Pharmacopœia, which is essentially the sesquioxide of iron, is deprived of water by calcination, and then subjected to the reducing influence of a stream of hydrogen, purified from sulphuretted hydrogen and other acid by passing successively through a solution of subacetate of lead and milk of lime. The hydrogen unites with the oxygen of the sesquioxide to form water, and leaves the iron in the metallic state. The subcarbonate should be perfectly free from sulphate of soda, which it is apt to contain when imperfectly washed. If this salt be present it will be reduced by the hydrogen to the state of sulphuret of sodium, which will contaminate and spoil the metallic iron formed, and cause the preparation, when taken, to give rise to unpleasant eructations. The heat should be carefully regulated; for if it fall below dull redness, part of the oxide will escape reduction; and, if it exceed that point considerably, the particles of reduced iron will agglutinate, and the preparation will be heavy and not readily pulverizable. The British process is not so well fitted for practical purposes as that of the U. S. Pharmacopœia. The direction to dry the hydrogen is unnecessary. On the subject of powder of iron, manufacturing chemists will find it useful to consult the paper of MM. Soubeiran and Dublanc, in which full directions are given for purifying the hydrogen, constructing the furnace, regulating the heat, and avoiding explosions. (*Amer. Journ. of Pharm.*, xviii. 303; from the *Journ. de Pharm.*, viii. 187.) Prof. Procter, of Philadelphia, has made some improvements in the process of Soubeiran and Dublanc, which he has communicated in a paper, embracing many useful details. (*Amer. Journ. of Pharm.*, xix. 11.)

Since the tenth edition of this work was published, several processes have been proposed for obtaining powder of iron. Mr. Arthur Morgan, of Dublin, recommends the use of dried ferrocyanide of potassium, thoroughly mixed with anhydrous red oxide of iron, and calcined with pure carbonate of potassa at a low red heat. The product contains all the iron in a reduced state, mixed with soluble matters, which are carefully washed away. (See *Amer. Journ. of Pharm.*, Sept. 1854, p. 450.) A similar process to the above has been proposed by a

German chemist, named Zängerle; the oxalate of protoxide of iron being substituted for the red oxide. (See *Pharm. Journ.*, May, 1857, p. 565.) Prof. Wöhler recommends the use of the same oxalate, not in connection with ferrocyanide of potassium; but as a suitable compound of iron for reduction by hydrogen. Oxalate of protoxide of iron is a salt of a lemon-yellow colour, and may be obtained by precipitating a concentrated solution of sulphate of iron with oxalic acid. Another eligible compound for reduction is the crystalline powder of oxide of iron, prepared by fusing, in a clay crucible, pure dried sulphate of iron with three times its weight of chloride of sodium, and then washing the melted mass when cold, until everything soluble is removed. (*Wöhler.*) The process of M. Eugene Fegueux consists in reducing the oxide of iron by carbonic oxide, formed by passing a stream of carbonic acid over red-hot charcoal in the reduction-tube, before it reaches the oxide of iron. The carbonic acid, thus reduced to carbonic oxide, is formed again by the deoxidizing of the ferruginous oxide.

Under the name of "*alcoholized iron*," a powder of iron has been introduced into this country, said to be prepared, in the eastern parts of Germany, by attrition of iron filings with honey, by some cheap method, as by attachment to a saw-mill or steam machinery. It has the appearance of powdered plumbago, but under the magnifying glass is seen to contain particles with the metallic lustre, and rounded as if by friction. It is soluble in dilute sulphuric acid, with the escape of hydrogen free or nearly so from sulphur; but a small quantity of a black powder remains undissolved. (*Am. Journ. of Pharm.*, Jan. 1867, p. 11.) The relation of the epithet "alcoholized" to this powder is not very obvious. Prof. Procter authorizes us to state that it is not much inferior to reduced iron, and is better than some that is sold by that name.

Properties. Powder of iron, called by the French, *fer reduit*, is a light, tasteless powder, soft to the touch, of an iron-gray colour, and without metallic lustre. If black the preparation is to be rejected as not being fully deoxidized. When thrown into a dilute acid, it causes a lively effervescence of hydrogen without odour. A small portion of it, struck on an anvil with a smooth hammer, forms a scale, having a brilliant metallic lustre. It takes fire upon the application of a burning body. On account of its great liability to oxidation, it should be kept in a dry bottle, well stopped. A black powder, having a composition corresponding with that of the magnetic oxide of iron, has been sold in London and Edinburgh under the name of Quevenne's iron. The spurious powder may be known by its having a black instead of an iron-gray colour, and by its effervescing but slightly with acids. In the process for making reduced iron, part of the sesquioxide almost always escapes full deoxidation, and comes out of the tube of a black colour. This part should be rejected, instead of being sold as reduced iron, as appears to have been done by some manufacturing chemists. If the preparation has been very badly made, its solution in dilute sulphuric acid will produce an intensely red colour with sulphocyanide of potassium.

Medical Properties. Powder of iron, reduced from the oxide by hydrogen, was first prepared for medicinal purposes by Quevenne and Miquelard, of Paris. The general therapeutic properties of the preparations of iron, and the mode in which they should be given, have been stated under another head. (See *page* 403.) Of these, the preparation under consideration is among the most important. It is that which introduces the largest proportion of iron into the gastric juice, according to Quevenne, and to M. Costes, of Bordeaux. The chief objection to it is the difficulty of obtaining it well prepared. Much of the powder of iron found in the shops is not to be depended on, in consequence of imperfect reduction. The principal diseases in which it has been employed are anæmia, chlorosis, amenorrhœa, chorea, and enlargement of the spleen following intermittent fever. Its general mode of action is to improve the quality of impoverished blood. Observations to determine its therapeutic value, compared with that of the other ferruginous preparations, were made by M. Costes, for nearly

four years, at the hospital Saint-André, of Bordeaux, and with results highly favourable to it. The dose is from three to six grains several times a day. given in powder or pill. It is sometimes prepared with chocolate in the form of lozenges. B.

GLYCERATA.

Glycerates.

Syn. GLYCERINA. *Br. Glycerines.*

These are solutions of medicinal substances in glycerin. Various names have been given to the class, of which the one at the head of this article, which was proposed in a previous edition of the Dispensatory, appears to us, on the whole, preferable to any of those hitherto brought into notice, and especially so to that adopted by the British Pharmacopœia, which is very objectionable. The nomenclature of these preparations is discussed in a note below, not only from the want of space in the text, but because the subject, being of only temporary interest, may thus be dropped without inconvenience when no longer requiring attention.*

Glycerin has valuable properties as a solvent and vehicle of medicinal substances. Such are its not unpleasant taste and bland character; its wide range of solvent power, which adapts it sometimes as a menstruum where neither water nor alcohol could be advantageously used, and enables it to retain in solution insoluble substances so frequently deposited from infusions and decoctions; and its preservative influence, which often protects against oxidation, and, by a destructive agency upon all of the lowest forms of vegetable and animal life, prevents the various fermentative processes so destructive of organic bodies. Another important property, as a vehicle for external remedies, is the permanence of its liquid character, so that it does not, like water and alcohol, dry up when applied to the skin; resembling in this respect, as well as in its demulcent quality, the fixed oils, without their tendency to rancidity. Hence it has of late come into extensive use in the preparation of medicinal solutions, which have been adopted in the present edition of the British Pharmacopœia,

* *Nomenclature of Glycerin Solutions.* The French denominated them *glycerolés*, with the accent on the last syllable, which is not an inappropriate name; but, transformed as it was, when adopted into the English, into *glyceroles*, is quite another term, and inadmissible, as this termination has long been applied to certain proximate organic principles, as *benzole*, *styrole*, *&c.* The name of *glycerinum* or *glycerine* of the several substances is, we think, still more objectionable. The preposition *of* before the name of the substance dissolved, implies a relation of ownership or of origin with the antecedent substance. Thus, *glycerinum amyli* or *glycerine of starch* implies that the glycerin was a part of the starch, or in some manner proceeded from it, or was formed by it. This would be true of such titles as *glycerine of olive oil*, *glycerine of fat*, &c., because glycerin absolutely proceeds from oils; also as *glycerine of soap* or *of lead plaster*, because it is contained in those products as first prepared; but it is in no sense true of the words as used in the Br. Pharmacopœia. In support of the British nomenclature its analogy has been adduced with that of the *Waters* and *Spirits*, as Water and Spirit of Peppermint. But these titles are exceptions to regular usage, the solutions in water being in general officinally denominated *Liquores* or *Solutions*, and those in alcohol or spirit *Tincture* or *Tinctures;* and the officinal terms Waters and Spirits were originally applied to liquids distilled from medicinal substances, to which they might, therefore, be considered as belonging, as in the above example of Water and Spirit of Peppermint, obtained by distilling water and spirit respectively from the herb; and were afterwards retained when these preparations came to be made, as is now the case with most of them, by simple solution of the essential oil or other volatile substance in water or alcohol. The name of *glycerata* or *glycerates*, used in this work, has been objected to, so far as we know, only on the ground of interference with the salts of glyceric acid, which must be called glycerates; but this acid is little known, never pharmaceutically used, and therefore not likely to come practically into conflict with the nomenclature here adopted; and, were it otherwise, it would be easy to change the name of glyceric into glycerinic acid. Besides, it is only the English names about which there could be any difficulty, as the Latin title is *glyceratum* in the singular, and not *glyceras*, and in the plural *glycerata*, and not *glyceratés*, which would be the title of the salts. (*Note to the thirteenth edition.*)

and under the name of *Glycérês* have found admission into the French Codex of 1866.

GLYCERATUM ACIDI CARBOLICI. *Glycerate of Carbolic Acid.* GLYCERINUM ACIDI CARBOLICI. *Br.* *Glycerine of Carbolic Acid.*

"Take of Carbolic Acid *one ounce* [avoirdupois]; Glycerine *four fluidounces* [Imperial measure]. Rub them together in a mortar until the Acid is dissolved." *Br.*

For the uses of this preparation, see *Acidum Carbolicum* in *Part* I. (*page* 43). It may be used internally or locally, and for both purposes should in general be diluted with water at the time of application. Four and a half minims represent about a grain of the acid. The dose is from five to ten minims. W.

GLYCERATUM ACIDI GALLICI. *Glycerate of Gallic Acid.* GLYCERINUM ACIDI GALLICI. *Br.* *Glycerine of Gallic Acid.*

"Take of Gallic Acid *one ounce* [avoirdupois]; Glycerine *four fluidounces* [Imperial measure]. Rub them together in a mortar, then transfer the mixture to a porcelain dish and apply a gentle heat until complete solution is effected." *Br.*

Glycerin is peculiarly fitted for a vehicle of gallic acid, which it readily dissolves, while the acid is but sparingly soluble in water. For the uses of this glycerate, see *Acidum Gallicum* in *Part* II. (*page* 959). The solution contains one grain of gallic acid in about four and a half minims of glycerin, and the dose is from twenty to sixty minims. W.

GLYCERATUM ACIDI TANNICI. *Glycerate of Tannic Acid.* GLYCERINUM ACIDI TANNICI. *Br.* *Glycerine of Tannic Acid.*

"Take of Tannic Acid *one ounce* [avoirdupois]; Glycerine *four fluidounces* [Imperial measure]. Rub them together in a mortar, then transfer the mixture to a porcelain dish and apply a gentle heat until a complete solution is effected."

This preparation may be used, both internally and externally, for most of the purposes to which tannic acid is applied. (See *Acidum Tannicum*, page 979.) Dr. S. Ringer esteems it highly as a remedy in ozæna and other sanious or purulent discharges from the nostrils and ears, being omitted if the symptoms present an acute form. He has found it also very serviceable in the early stages of eczema, and in impetigo; the scabs being removed before it is applied; and considers it extremely useful in chronic inflammation and superficial ulceration of the fauces, with a relaxed, moist, and granular appearance of the pharyngeal mucous membrane. (*Am. Journ. of Med. Sci.*, Jan. 1869, p. 241.) The solution contains one grain of tannic acid in between four and five minims; and the dose is from ten to forty minims. W.

GLYCERATUM AMYLI. *Glycerate of Starch.* GLYCERINUM AMYLI. *Br.* *Glycerine of Starch.*

"Take of Starch *one ounce* [avoirdupois]; Glycerine *eight fluidounces* [Imperial measure]. Rub them together until they are intimately mixed, then transfer the mixture to a porcelain dish, and apply a heat gradually raised to 240°, stirring it constantly until the starch particles are completely broken and a translucent jelly is formed." *Br.*

Of this preparation it is only necessary to say that, with the exception of an inconsiderable difference in the proportions, it is the same with that brought into notice ten years since by Mr. Schacht, and described under *Glycerin* in *Part* I. of the Dispensatory (*page* 433), to which the reader is referred. W.

GLYCERATUM BORACIS. *Glycerate of Borax.* GLYCERINUM BORACIS. *Br.* *Glycerine of Borax.*

"Take of Borax, in powder, *one ounce* [avoirdupois]; Glycerine *four fluidounces*. Rub them together in a mortar until the Borax is dissolved." *Br.*

The demulcent properties and sweet taste of this preparation render it a useful and convenient method of applying borax to the infantile thrush, and other forms of sore-mouth in children.* W.

HYDRARGYRUM.

Preparations of Mercury.

Of the mercurial preparations formerly officinal, the following have been discarded in the recent editions of the U. S. and British Pharmacopœias; *Pure Mercury*, Dub., *Solution of Bichloride of Mercury*, Lond., *Black Oxide of Mercury*, U. S., *Black Sulphuret of Mercury*, U. S., and *Mercury with Magnesia*, Dub. The *Solution of Nitrate of Mercury* has been transferred to the Liquores or *Solutions*.

HYDRARGYRI CHLORIDUM CORROSIVUM. *U. S.* Hydrargyri Perchloridum. *Br.* Hydrargyrum Corrosivum Sublimatum. *Br.* 1864. Hydrargyri Bichloridum. *Lond.* *Corrosive Chloride of Mercury. Perchloride of Mercury. Bichloride of Mercury. Corrosive Sublimate.*

"Take of Mercury *twenty-four troyounces;* Sulphuric Acid *thirty-six troyounces;* Chloride of Sodium *eighteen troyounces.* Boil, by means of a sand-bath, the Mercury with the Sulphuric Acid until a dry white mass is left. Rub this, when cold, with the Chloride of Sodium in an earthenware mortar; then sublime with a gradually increasing heat." *U. S.*

"Take of Sulphate of Mercury *twenty ounces* [avoirdupois]; Chloride of Sodium, dried, *sixteen ounces* [avoird.]; Black Oxide of Manganese, in fine powder, *one ounce* [avoird.]. Reduce the Sulphate of Mercury and the Chloride of Sodium each to fine powder, and, having mixed them and the Oxide of Manganese thoroughly by trituration in a mortar, put the mixture in an apparatus adapted for sublimation, and apply sufficient heat to cause vapours of perchloride of mercury to rise into the less heated part of the apparatus which has been arranged for their condensation." *Br.*

In order to understand the above processes, which are the same in principle, it is necessary to premise that corrosive sublimate is a bichloride of mercury, consisting of two eqs. of chlorine and one of mercury. By boiling sulphuric acid in excess with mercury to dryness, a white salt is formed, which is a bisulphate of the deutoxide of mercury. (See *Hydrargyri Sulphas.*) When this is mixed with chloride of sodium (common salt), and the mixture exposed to a subliming heat, a mutual decomposition takes place. The chlorine of the common salt combines with the mercury, and sublimes as bichloride of mercury; while the sodium, oxygen of the deutoxide of mercury, and sulphuric acid unite to form

* *Glyceratum Picis Liquidæ. Glycerate of Tar.* Glycerin is probably the best vehicle for the exhibition of tar in the liquid state, dissolving as it does much of its active matter, and by its demulcent properties covering in a considerable degree the acrimony of the tar. The following formula is given, by Mr. J. B. Moore, in the American Journal of Pharmacy for March, 1869 (p. 115). The proper place for noticing it would have been under Tar, in Part I., but that part of the work had passed through the press before this number of the journal appeared. Take of Tar (strained) *a troyounce;* Carbonate of Magnesia, powdered on a sieve, *three troyounces;* Alcohol *two fluidounces;* Glycerin *four fluidounces;* Water *a sufficiency.* Mix the Alcohol and Glycerin with ten fluidounces of water. Rub the Tar in a mortar, first with the Carbonate of Magnesia gradually added, and then, for 15 or 20 minutes, a small portion being added at a time, with six fluidounces of the liquid mixture, and strain with strong expression. This process of trituration is repeated twice with the residue and additional portions of the mixed liquids; after which the residuary matter is subjected to percolation with the expressed liquids, previously mixed; the percolation being completed with water. The amount of the percolate is a pint. At first the glycerate is reddish brown and clear; but after a time deposits inert pitchy matter, which may be readily separated by filtration without impairing the virtues of the preparation. Each fluidounce represents about thirty grains of tar. The dose is from about f℥ij to f℥iv. Mr. Moore thinks that the place of the alcohol might with little disadvantage be supplied by glycerin. (*Note to the thirteenth edition.*)

sulphate of soda, which remains behind. The quantities for mutual decomposition are two eqs. of chloride of sodium, consisting of two eqs. of chlorine and two of sodium; and one eq. of bisulphate of deutoxide of mercury, consisting of one eq. of mercury, two of oxygen, and two of sulphuric acid. The two eqs. of chlorine combine with the one eq. of mercury to form one eq. of corrosive sublimate; and the two eqs., severally, of sodium, oxygen, and sulphuric acid form, by their union, two eqs. of dry sulphate of soda. The British formula differs from ours in ordering the bisulphate of the deutoxide of mercury ready formed, under the name of sulphate of mercury, instead of preparing it as the first step of the process, and in the use of a small proportion of black oxide of manganese, intended to deutoxidize any portion of protoxide of mercury that may be contained in the sulphate, and thereby prevent the formation of protochloride of mercury or calomel. (See *Hydrargyri Sulphas.*)

The names given in the two Pharmacopœias to this important chloride do not exactly correspond. It is called the corrosive chloride of mercury in the U. S. Pharmacopœia and perchloride in the British. We prefer the former as indicating beyond any possibility of mistake, as well the article intended as its corrosive property. Perchloride and subchloride are hardly sufficiently distinctive, when a mistake may be so serious as that of confounding corrosive sublimate and calomel. In the first British Pharmacopœia corrosive sublimate was recognized as the officinal title, which was a sufficient guarantee of security; but, unfortunately, it was deemed proper, immediately after the officinal title, and in close connection with it, to define the salt as chloride of mercury, in conformity with the new view, adopted in that work, of the equivalent of mercury. Now this view is by no means universally accepted, and with many, calomel is still the chloride of mercury; so that there is some chance that, should calomel be prescribed by this title, corrosive sublimate may be dispensed for it, with dangerous if not fatal effects to the patient. Indeed, death has, at least in one recorded instance, occurred in consequence of this confusion of nomenclature; and our officinal guides should take especial care to guard against such mistakes, instead of contributing to them.

Preparation on the Large Scale, &c. The first step is to form the bisulphate of the deutoxide of mercury, which is effected by heating the sulphuric acid and metal together in an iron pot, so arranged as to carry off the unwholesome fumes of sulphurous acid, which are copiously generated. The dry salt obtained is then mixed with the common salt, and the mixture sublimed in an iron pot lined with clay, and covered by an inverted earthen pan. The late Dr. A. T. Thomson, of London, took out a patent for forming corrosive sublimate, on the large scale, by the direct combination, by combustion, of gaseous chlorine with heated mercury. The product is stated to be perfectly pure, and to be afforded at a lower price than the sublimate made in the usual way. In order that the combination may take place, the mercury need not be heated to its boiling point, but only to a temperature between 300° and 400°. According to Dr. Maclagan, corrosive sublimate, made by this process, is liable to the objection that a proportion of calomel is always formed, occasionally amounting to 10 per cent.

It may sometimes be useful to know how to make a small quantity of corrosive sublimate on an emergency. This may be done by dissolving deutoxide of mercury (red precipitate) in muriatic acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. Here a double decomposition takes place, resulting in the formation of water and the bichloride.

Properties. Corrosive chloride of mercury, as obtained by sublimation, is in the form of colourless crystals, or of white, semi-transparent, crystalline masses, of the sp. gr. 5·2, permanent in the air, and of an exceedingly acrid, styptic, metallic, durable taste. Its temperature of sublimation is, according to Guy, 200° F. (*Pharm. Journ.*, Feb. 1868, p. 375.) It dissolves in 16 parts of cold water, and in 3 of boiling water. A boiling saturated solution, upon cooling, lets it fall in a confused mass of crystals. It is soluble also in 2·3 parts of cold alcohol, in about its own weight of boiling alcohol, and in 3 parts of ether. The

latter solvent is capable of removing corrosive sublimate, to a considerable extent, from its aqueous solution, when agitated with it. According to M. Mialhe, ether will not dissolve it when accompanied by a considerable quantity of deutoxide of mercury, and a chloride of an alkalifiable metal. Sulphuric, nitric, and muriatic acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapours, which condense, on cool surfaces, in white shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum.*) The former precipitate is the hydrated deutoxide of mercury, which has the property of emitting oxygen, and of being reduced to metallic globules when exposed to heat. This oxide is formed in the process for preparing *aqua phagedænica*, called also *lotio flava* or *yellow wash*, which is obtained by mixing half a drachm of corrosive sublimate with a pint of lime-water. Corrosive sublimate forms with muriate of ammonia and chloride of sodium, compounds which are more soluble than the uncombined mercurial salt. It is on this account that aqueous solutions of sal ammoniac, or of common salt, dissolve much more corrosive sublimate than simple water. The combination of corrosive sublimate with muriate of ammonia was formerly called *sal alembroth* or *salt of wisdom.* According to F. Hinterberger, corrosive sublimate is capable of combining with quinia and cinchonia. (*Chem. Gaz.*, ix. 211.)

Corrosive sublimate has the property of retarding putrefaction. Animal matters, immersed in its solution, shrink, acquire firmness, assume a white colour, and become imputrescible. On account of this property it is usefully employed for preserving anatomical preparations.

Test of Purity and Incompatibles. Pure corrosive chloride of mercury sublimes, when heated, without residue, and its powder is entirely and readily soluble in ether. Consequently, if a portion of any sample should not wholly dissolve in ether, or if it should not evaporate entirely, the presence of some impurity is proved. If calomel be present, it will not be wholly soluble in water. Corrosive sublimate is incompatible with many of the metals, the alkalies and their carbonates, soap, lime-water, tartar emetic, nitrate of silver, the acetates of lead, the sulphurets of potassium and sodium, the soluble iodides, and all the hydrosulphates. It is decomposed by many vegetable and some animal substances. According to Dr. A. T. Thomson, it produces precipitates in infusions or decoctions of chamomile, horse-radish, columbo, catechu, cinchona, rhubarb, senna, simaruba, and oak-bark. MM. Mialhe and Lepage have shown that corrosive sublimate is slowly converted into calomel by syrup of sarsaparilla and syrup of honey, but is not changed by contact with pure syrup. B.

Medical Properties and Uses. Corrosive sublimate is a very powerful preparation, operating quickly, and, if not properly regulated, producing violent effects. It is less apt to salivate than most other mercurials. In minute doses, suitably repeated, it may exert its peculiar influence without any obvious alteration of the vital functions, except, perhaps, a slight increase in the frequency of the pulse, and in the secretions from the skin and kidneys. Sometimes, however, it purges; but this effect may be obviated by combining it with a little opium. In larger doses it occasions nausea, vomiting, griping pain in the bowels, diarrhœa, and other symptoms of gastric and intestinal irritation; and in still larger quantities produces all the effects of a violent corrosive poison. It has long been used as a remedy in syphilis, in all stages of which it has been highly recommended. It is said to remove the symptoms more speedily than other mercurials; whilst its action is less unpleasant, as the mouth is less liable to be made sore. For the latter reason it has been much employed by empirics, and is an ingredient in most of those nostrums which have at various periods gained a temporary popularity as anti-venereals. But, while it is extolled by some authors, others, among whom is Mr. Pearson, of London, deny its extraordinary merits, and maintain that, though occasionally useful in arresting the progress of the complaint, particularly in the secondary stage, it does not produce per-

manent cures, and, in the primary stage, often fails altogether. On the whole it appears to be best adapted to secondary syphilis, in which it occasionally does much good. It is also used advantageously in some chronic cutaneous affections, and in obstinate chronic rheumatism. It is usually associated with alterative or diaphoretic medicines, such as the antimonials, and the compound decoction or syrup of sarsaparilla; and, in order to obviate the irritation it is apt to produce, it may often be advantageously united with opium, or extract of hemlock. There is no doubt that many of the substances, in connection with which it is employed, alter its chemical condition; but it does not follow that, even in its altered state, it may not be very useful as a remedy.

Externally employed, corrosive sublimate is stimulant and escharotic. A solution in water, containing from an eighth to half a grain in the fluidounce, is employed as an injection in gleet, as a gargle in venereal sorethroat, and as a collyrium in chronic venereal ophthalmia. A stronger solution, containing one or two grains in the fluidounce, is an efficacious wash in lepra, and other scaly eruptions. Dissolved in water, in the proportion of five to ten grains to the fluidounce, it may be used with much benefit in venereal ulcers of the throat, to which it should be applied by means of a camel's-hair pencil. With lime-water it forms the *aqua phagedænica* of the older writers, employed as a wash for ill-conditioned ulcers. The powdered chloride has been used as an escharotic; but is, in general, inferior to nitrate of silver or caustic potassa. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of sulphate of zinc, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the ulcer heals. This practice originated, we believe, with the late Dr. Perkins, of Philadelphia, and was highly recommended by Dr. Physick. We have often employed it with complete success. A solution of corrosive sublimate in collodion, in the proportion of four parts of the former to thirty of the latter, has of late been used as a caustic, for the destruction of nævi materni, and for other purposes. It has the advantages that it may be applied to parts of inconvenient access for ordinary caustics, and forms a well-defined boundary, without risk of spreading. It is applied by means of a camel's-hair pencil.

The dose of corrosive sublimate is from the twelfth to the quarter of a grain, repeated three or four times a day, and given in pill, or dissolved in water or spirit. The pill, which is the preferable form, is usually prepared with crumb of bread; and care should be taken that the medicine be equally diffused through the pilular mass, before it is divided. Mucilaginous drinks are usually given to obviate the irritating effects of the medicine.

Toxicological Properties. Swallowed in poisonous doses, it produces burning heat in the throat, excruciating pain in the stomach and bowels, excessive thirst, anxiety, nausea and frequent retching with vomiting of bloody mucus, diarrhœa and sometimes bloody stools, small and frequent pulse, cold sweats, general debility, difficult respiration, cramps in the extremities, faintings, insensibility, convulsions, and death. The mucous membrane of the stomach exhibits, on dissection, signs of the operation of a violent corrosive poison. These symptoms are sometimes followed or conjoined with others indicating an excessive mercurial action upon the system, such as inflammation of the mouth and salivary glands, profuse salivation, fetid breath, &c. A case is on record of death, in an infant, from the constitutional effects of corrosive sublimate sprinkled upon an excoriated surface; and, in two instances of children, the one seven, and the other nine years old, death, with all the symptoms of internal poisoning, followed the application to the scalp of an ointment, said to consist of one part of the corrosive chloride to four parts of tallow. (*Dub. Quarterly*, Aug. 1854, p. 70.) In the inferior animals, in whatever mode introduced into the system, it is said to occasion irritation of the stomach and rectum, inflammation of the lungs, oppression of the brain, and depression if not inflammation of the heart. (*Christison.*) In the treatment of poisoning by corrosive sublimate, Orfila re-

commends the free use of the white of eggs beat up with water. The albumen forms an insoluble and comparatively innocent compound with the corrosive sublimate; and the liquid by its bulk dilutes the poison, and distends the stomach so as to produce vomiting. It is, however, asserted by M. Lassaigne that this compound of albumen and corrosive sublimate, when recently precipitated, is soluble in acid and alkaline liquids, and in solutions of the chlorides of potassium, sodium, and calcium. (See *Journ. de Pharm.*, xxiii. 510.) It is also soluble in an excess of albumen, whether introduced into the stomach, or previously existing there. It is, therefore, important, at the same time that the antidote is used, to evacuate the stomach before the newly formed compound can be dissolved. If eggs cannot be procured, wheat flour may be substituted; gluten having, according to M. Taddei, the same effect as albumen. Milk has also been recommended, in consequence of the insoluble compound which casein forms with the poison. Besides the antidotes mentioned, Peruvian bark, meconic acid, protosulphuret of iron, and iron filings have been proposed, all of which have the property of decomposing corrosive sublimate. The protosulphuret of iron was found quite successful by M. Mialhe in experiments upon dogs, if given immediately after the poison was swallowed, but failed when delayed for ten minutes. Dr. T. H. Buckler, of Baltimore, made some experiments on lower animals upon the antidotal properties of a mixture of gold dust and iron filings, which, proving successful, were published in the *Medical and Surgical Journal* in 1843; and a case of poisoning by corrosive sublimate has recently been recorded by Dr. Ch. Johnston, of the same city, in which the antidote was employed with the apparent effect of saving life, after albumen had been used without effect. Dr. Johnston, however, employed the reduced iron of the Pharmacopœia, and gold leaf, arranging them in alternate layers, so as to make boluses of convenient size. (*Am. Journ. of Med. Sci.*, April, 1863, p. 340.) The method of operating of this antidote will be understood when the action of gold and iron as a test for corrosive sublimate is explained in the succeeding paragraph. It is of the utmost importance that whatever antidote is used should be given without delay, and in this respect the one nearest at hand may be considered the best. Should neither of the substances mentioned be attainable, mucilaginous drinks should be largely administered; and, in any event, the patient should be made to drink copiously, so long as vomiting continues, or till the symptoms are relieved. Should he be unable to vomit, the stomach should be washed out by means of the stomach-pump. The consecutive inflammation should be treated with general or local bleeding, fomentations, and cooling mucilaginous drinks; and the attendant nervous symptoms should be alleviated by opiates. W.

Tests for Corrosive Sublimate. On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations. The best tests for determining its mercurial nature, mentioned in the order of their delicacy, are ferrocyanide of potassium, lime-water, carbonate of potassa, iodide of potassium, ammonia, sulphuretted hydrogen, and protochloride of tin. *Ferrocyanide of potassium* gives rise to a white precipitate (ferrocyanide of mercury), becoming slowly yellowish, and at length pale-blue. *Lime-water* throws down a yellow precipitate of hydrated deutoxide. *Carbonate of potassa* causes a brick-red precipitate of carbonate of mercury. *Iodide of potassium* produces a very characteristic pale-scarlet precipitate of biniodide of mercury. This precipitate frequently appears at first yellow, especially if the corrosive sublimate be present in minute proportion. *Ammonia* gives rise to a white, flocculent precipitate, the officinal ammoniated mercury, or white precipitate. *Sulphuretted hydrogen* occasions a black precipitate of bisulphuret of mercury; and the same precipitate is thrown down by hydrosulphuret of ammonia. Finally, *protochloride of tin* causes a grayish-black precipitate (mercury in a finely divided state), and, as a test, is not liable to any fallacy. Taking the results of Devergie, the relative delicacy of these tests may be expressed numerically as follows:—Ferrocyanide of potassium $1\frac{1}{2}$; lime-water 4; carbonate of potassa 7;

iodide of potassium 8; ammonia 36; sulphuretted hydrogen or hydrosulphuret of ammonia 60; and protochloride of tin 80. To the above the following tests may be added, easily applied even by one unacquainted with chemistry. *A bright plate of copper*, immersed in a solution containing corrosive sublimate, is instantly tarnished, and, after the lapse of half an hour, becomes covered with a grayish-white powder. *A polished piece of gold*, moistened with the *clear* mercurial solution, and touched through the liquid with a piece of iron, contracts a white stain. This test, which was proposed by Mr. Sylvester and simplified by Dr. Paris, is conveniently applied by moistening, with the suspected solution, a gold coin or ring, and touching it through the moistened spot with the point of a penknife. The object of the iron is to form with the gold a simple galvanic circle, which enables the latter metal to precipitate the mercury on its surface. Nearly all the above tests merely prove the presence of mercury. To determine whether the metal is united with chlorine, the mercurial liquid may be precipitated by lime-water, and the filtered solution, acidulated with nitric acid, then tested with nitrate of silver. If the mercury is in the state of chloride, the filtered solution will be one of chloride of calcium, which, with nitrate of silver, will yield a heavy white precipitate (chloride of silver), insoluble in nitric acid, but soluble in ammonia. The nitrate of silver may be added directly to the mercurial liquid; and, if it contain corrosive sublimate, chloride of silver will fall, but probably mixed with calomel.

By the combined indications of the foregoing tests, corrosive sublimate may be infallibly detected, unless it exists in very minute quantity, associated with organic substances, by which its presence is often greatly obscured. When it exists in organic mixtures, made by boiling the contents or substance of the stomach in distilled water, Dr. Christison recommends that a preliminary trial be made with the protochloride of tin, on a small portion filtered for the purpose. If this causes a grayish-black colour, he shakes the mixture, as recommended by Orfila, with a fourth of its bulk of cold ether, which dissolves the corrosive sublimate, and rises to the surface. The ethereal solution is then evaporated to dryness, and the dry salt obtained is dissolved in hot water, whereby a pure solution is procured, in which the poison may be readily detected by the ordinary tests. In using ether, however, it must be borne in mind that, as ascertained by M. Mialhe, the presence of a considerable quantity of deutoxide of mercury, and of a chloride of an alkalifiable metal, prevents the solvent power of ether. If the trial test should produce a light-gray colour, the corrosive sublimate is indicated in still less quantity, and Dr. Christison recommends to proceed in the following manner. Treat the unfiltered mixture with protochloride of tin, as long as any precipitate is formed, which will have a slate-gray colour. Collect, wash, and drain it on a filter, and, having removed it without being dried, boil it, in a glass flask, with a moderately strong solution of caustic potassa, until all the lumps disappear. The alkali will dissolve all animal and vegetable matter; and, on allowing the solution to remain at rest, a heavy grayish-black powder will subside, which consists chiefly of metallic mercury, and in which small globules of the metal may sometimes be seen with the naked eye, or by the aid of a magnifier. Probably advantage might be derived from the process of dialysis, in separating corrosive sublimate, among other crystallizable substances, from the colloidal matters contained in organic mixtures. (See *Dialysis*, p. 933.)

Off. Prep. Hydrargyri Iodidum Rubrum; Hydrargyrum Ammoniatum; Liquor Hydrargyri Perchloridi, *Br.*; Lotio Hydrargyri Flava, *Br.* B.

HYDRARGYRI CHLORIDUM MITE. *U. S.* HYDRARGYRI SUBCHLORIDUM. *Br.* CALOMELAS. *Br.* 1864. *Mild Chloride of Mercury. Subchloride of Mercury. Calomel.*

"Take of Mercury *forty-eight troyounces;* Sulphuric Acid *thirty-six troyounces;* Chloride of Sodium *eighteen troyounces;* Distilled Water *a sufficient quantity.* Boil, by means of a sand-bath, twenty-four troyounces of the Mercury with the Sulphuric Acid, until a dry white mass is left. Rub this, when cold,

with the remainder of the Mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the Chloride of Sodium, and, having rubbed it with the other ingredients until globules of Mercury cease to be visible, sublime the mixture. Reduce the sublimed matter to a very fine powder, wash it with boiling Distilled Water, until the washings afford no precipitate with water of ammonia, and dry it." *U. S.*

"Take of Sulphate of Mercury *ten ounces* [avoirdupois]; Mercury *seven ounces* [avoird.]; Chloride of Sodium, dried, *five ounces* [avoird.]; Boiling Distilled Water *a sufficiency*. Moisten the Sulphate of Mercury with some of the Water, and rub it and the Mercury together until globules are no longer visible; add the Chloride of Sodium, and thoroughly mix the whole by continued trituration. Sublime by a suitable apparatus into a chamber of such size that the Calomel, instead of adhering to its sides as a crystalline crust, shall fall as a fine powder on its floor. Wash this powder with boiling Distilled Water, until the washings cease to be darkened by a drop of sulphide of ammonium. Finally, dry at a heat not exceeding 212°, and preserve in a jar or bottle impervious to light." *Br.*

The object of the above processes is to obtain the protochloride of mercury. This chloride consists of one eq. of chlorine and one of mercury, and consequently contains precisely half as much chlorine as corrosive sublimate, combined with the same quantity of mercury. In the U. S. process, as in the case of corrosive sublimate, a bisulphate of the deutoxide is first formed; but, instead of being immediately sublimed with the chloride of sodium, it undergoes a preparatory trituration with a quantity of mercury equal to that employed in forming it. This trituration may be conceived to take place between one eq. of bisulphate of the deutoxide, and one of metallic mercury, which are thus converted into two eqs. of monosulphate of the protoxide. This change will be easily understood, by adverting to the fact, that the bisulphate of the deutoxide consists of two eqs. of sulphuric acid, two of oxygen, and one of mercury; and, when rubbed up with one additional eq. of mercury, the whole becomes two eqs. of acid, two of oxygen, and two of mercury, evidently corresponding with two eqs. of monosulphate of the protoxide. The two eqs. of monosulphate thus formed, being heated with two of common salt, the two eqs. of chlorine in the latter sublime in union with the two of mercury in the former, and generate two eqs. of protochloride of mercury; while the two eqs. severally, of sulphuric acid, oxygen, and sodium, unite together to form two of dry sulphate of soda, which remain as a fixed residue. It is hence apparent that the residue of this process and of that for corrosive sublimate is the same.

The calomel in mass, as sublimed, is liable to contain a little corrosive sublimate; and hence the direction of the U. S. Pharmacopœia to reduce the sublimed matter to a very fine powder, and to wash it with boiling distilled water until ammonia produces no precipitate with the washings. Ammonia occasions a white precipitate (ammoniated mercury) so long as the washings contain corrosive sublimate; and, when it ceases to produce this effect, the operator may rest satisfied that the whole of the poisonous salt has been removed. According to M. Berthé, calomel, in contact with hot water, is converted, to a small extent, into corrosive sublimate; and hence he recommends that the portion of water to be tested should be cold when passed through the calomel.

The British process is a modification of that of the late Dublin Pharmacopœia, including, like that, no directions for making the bisulphate of the deutoxide of mercury; because this salt is made by a separate formula, being designated as *sulphate of mercury*. It omits, however, as unnecessary, a partial preliminary sublimation, directed by the Dublin College, to test the production of corrosive sublimate, and, immediately after a thorough mixture of the materials, proceeds to the final sublimation. A special proceeding, in which the Dublin process is followed, is to cause the vapours to enter for condensation a chamber of considerable size, so that they may fall in powder, instead of condensing on the sides of the receiver in a crystalline mass. The necessity of pulverizing the

calomel is thus avoided. As our own, the Br. Pharmacopœia directs the powder to be washed; but, instead of using ammonia as a test of the absence of corrosive sublimate in the washings, directs for the purpose sulphide of ammonium, which throws down a black precipitate if corrosive sublimate is present.

Preparation on the Large Scale. The process for making calomel, by means of the bisulphate of deutoxide of mercury, was originally practised at Apothecaries' Hall, London. The proportions taken and the mode of proceeding in that establishment are, according to Mr. Brande, as follows: 50 lbs. of mercury are boiled to dryness with 70 lbs. of sulphuric acid, in a cast-iron vessel; and 62 lbs. of the dry salt formed are triturated with 40½ lbs. of mercury till the globules disappear, and the whole is mixed with 34 lbs. of common salt. The mixture is sublimed from an earthenware retort into an earthenware receiver, and the product is from 95 to 100 lbs. of calomel in mass. This is then ground to an impalpable powder, and washed with a large quantity of distilled water.

The object of bringing calomel into a state of minute division is more perfectly accomplished by the method of Mr. Joseph Jewell, of London, improved by M. Ossian Henry. It consists in causing the calomel in vapour to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury*, is free from all suspicion of containing corrosive sublimate, is much finer than when obtained by levigation and elutriation, and possesses more activity as a medicine. This kind of calomel is included in the French Codex under a distinct name (*mercure doux à la vapeur*). M. Soubeiran, of Paris, has perfected a process for obtaining calomel as an impalpable powder, by substituting the agency of cold air for that of steam for the purpose of condensing it; a process which he believes to be precisely the same as that pursued by the English manufacturers, and which produces a calomel equal to the best English. A description of his apparatus may be found in the *Journal de Pharmacie* (3e sér., ii 507), and of the English apparatus, as described by F. C. Calvert, in the same journal (3e sér., iii. 121). Both these papers are copied into the *Am. Journ. of Pharm.* (xv. 89 and 93).

Prof. Wöhler has proposed to obtain calomel, in the humid way, by precipitating a solution of corrosive sublimate by a stream of sulphurous acid, taking advantage of a reaction first observed by Vogel. Calomel obtained in the humid way, called *precipitated calomel*, was formerly officinal with the Dublin College, and was adopted in the French Codex. This form of calomel is of doubtful utility; and, when obtained by Prof. Wöhler's process, it is a crystalline powder, which is a fatal objection to it.

Properties. Mild chloride of mercury is a tasteless, inodorous substance, insoluble in water, alcohol, and ether, less volatile than corrosive sublimate, unalterable in the air, but blackening by long exposure to the light. When in mass its form and appearance depend on the shape and temperature of the subliming vessel. In this state it is generally in the form of a white, fibrous, crystalline cake, the interior surface of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7·2. The officinal form of this chloride is that of powder, in which state it is always kept in the shops. The powder has a light buff or ivory colour, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, as is the case with Jewell's calomel, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black, or covered with black paper. By the action of the fixed alkalies or alkaline earths it immediately becomes black, in consequence of the formation of protoxide, reducible by heat to the metallic state. The preparation employed under the name of *lotio nigra* or *black wash*, as a local application to syphilitic ulcers, &c., is made by adding *a drachm* of calomel to *a pint* of lime-water. By double decomposition between

the calomel and lime, the black protoxide precipitates, and chloride of calcium remains in solution, indicated by yielding a copious white precipitate with nitrate of silver. The oxide, however, is not pure, but associated with undecomposed calomel. Before being applied, the wash should be well shaken.

Tests of Purity and Incompatibles. Calomel, when pure, completely sublimes on the application of heat, a property which detects all fixed impurities, such as carbonate, sulphate, and phosphate of lime, sulphate of baryta, and carbonate of lead. Under the influence of an elevated temperature, especially in the presence of alcohol or water, it gives rise to a small quantity of corrosive sublimate. (*M. Berthé.*) Calomel strikes a black colour, free from reddish tinge, by the action of the fixed alkalies; and the black oxide thus produced is brought by heat to the metallic state. The buff colour indicates the absence of corrosive sublimate; but whiteness by no means shows the presence of this impurity. Its freedom from the corrosive chloride may be determined by washing a portion of it in warm distilled water, and then testing the water with ammonia, which will cause a white precipitate (ammoniated mercury), should the water have taken up any of the poisonous chloride. An easy method of detecting corrosive sublimate, proposed by M. Bonnewyn, is to put some of the suspected powder upon a well-polished surface of iron, and then moisten it with a drop of alcohol or ether. If the calomel be pure the surface will remain quite unaffected, while it will be blackened by corrosive sublimate if present only in the proportion of one to 50,000. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 79.) The presence of any soluble chloride whatever in the calomel would be detected by the production of a precipitate with the washing by nitrate of silver. Soluble salts of mercury may be detected by rubbing the suspected calomel with ether on a bright surface of copper, when the metal will become amalgamated, and exhibit a white stain. When this test shows impurity, the soluble salt present is probably corrosive sublimate. Calomel, containing corrosive sublimate, acts violently on the bowels; and, when the impurity has been present in considerable amount, has been known to cause death. Besides being incompatible with the alkalies and alkaline earths, calomel is also decomposed by the alkaline carbonates, soaps, hydrosulphates, and, according to some authorities, by iron, lead, and copper. By boiling with the alkaline formiates it is decomposed, and metallic mercury liberated. (H. Rose, *Annal. der Physik und Chem.*, cvi. 500.) According to M. Lebeaux, calomel should not be prescribed with iodine; unless the prescriber intends to give biniodide (red iodide) of mercury, when the dose must be reduced accordingly. (*Annuaire de Thérap.*, 1857, p. 180.) It should not be given at the same time with nitromuriatic acid, for fear of generating corrosive sublimate. One of the authors has been informed of a case, in which death, with symptoms of violent gastro-intestinal irritation, followed their joint use. Agreeably to the experiments of M. Deschamps, calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, bicyanide of mercury, and muriate of ammonia are formed; in the latter, corrosive sublimate and bicyanide only. Hence this writer considers it very dangerous to associate calomel with bitter almonds or hydrocyanic acid in prescription. This conclusion has been confirmed by M. Mialhe and M. Prenleloup; and, more recently, it has been shown by Dr. E. Riegel that cherry-laurel water has the power of converting calomel into corrosive sublimate. According to M. Mialhe, calomel is in part converted into corrosive sublimate and metallic mercury by muriate of ammonia, and by the chlorides of sodium and potassium, even at the temperature of the body; and hence he believes that the conversion may take place in the primæ viæ. Popular belief coincides with M. Mialhe's views in regard to the power of common salt to increase the activity of calomel. More recently M. Mialhe has extended his observations, and now believes that all the preparations of mercury yield a certain amount of corrosive sublimate by reacting with solutions of the chlorides of potassium, sodium, and ammonium. The deutoxide and similarly constituted compounds are most prone to undergo this change. Even metallic mercury,

digested with the chlorides named, is partly converted, under the influence of the air, into corrosive sublimate. Dr. Gardner denies the assertion of M. Mialhe, that calomel is converted into corrosive sublimate by chlorides of the alkalifiable metals, maintaining that it is merely rendered soluble by their solutions. The results, however, of M. Mialhe have been confirmed experimentally by Dr. A. Fleming, of Pittsburg, Pa. (*Am. Journ. of Pharm.*, Sept. 1857.) M. Bauwens of Ghent, recognising the conversion of calomel into corrosive sublimate in the body by these chlorides, explains by this fact the relatively less powerful action of large than of small doses of calomel. He also states that physicians near the sea, where the water is brackish, seldom prescribe calomel, and that naval surgeons have been obliged to abstain from giving it to sailors who eat salt meat. Dr. H. Peake, of Arkadelphia, Arkansas, has known many instances in which salivation has been induced by the joint use of calomel and vegetable acids, in the forms of sour fruit, vinegar, buttermilk, &c., where the mercurial alone would not have induced it. (*N. O. Med. and Surg. Journ.*, Nov. 1858, p. 724.) B.

Medical Properties and Uses. Calomel unites to the general properties of the mercurials those of a purgative and anthelmintic. It is the most valuable of the mercurial preparations, and in extent of employment is inferior to few articles of the Materia Medica. Whether the object is to bring the system under the general influence of mercury, or to produce its alterative action upon the hepatic or other secretory function, calomel, on account both of its certainty and mildness, is preferred to all other preparations, with the single exception of the blue pill, which, though less certain, is still milder, and is sometimes preferably employed. When used with the above objects, the tendency to purge which it sometimes evinces, even in very small doses, must be restrained by combining it with opium. In sialagogue or alterative doses, it is often prescribed with other medicines, which, while they give it a direction to certain organs, have their own peculiar influence increased by its co-operation. Thus it renders squill more diuretic, nitre and the antimonials more diaphoretic, and seneka more expectorant.

As a purgative, calomel owes its chief value to its tendency to the liver, the secretory function of which it powerfully stimulates. It is usually slow and somewhat uncertain in its cathartic effect, and, though itself but slightly irritating, sometimes occasions severe griping pain with bilious vomiting, attributable to the acrid character of the bile which it causes the liver to secrete. It is peculiarly useful in the commencement of bilious fevers, in hepatitis, jaundice, bilious and painters' colic, dysentery, especially that of tropical climates, and all other affections attended with congestion of the portal system, or torpidity of the hepatic function. The difficulty with which it is thrown from the stomach renders it highly useful in some cases of obstinate vomiting, when other remedies are rejected. In the cases of children it is peculiarly valuable from the facility of its administration; and, in the febrile complaints to which they are subject, appears to exercise a curative influence, depending on some other cause than its mere purgative effect, and perhaps referrible to its action upon the liver. In the treatment of worms, it is one of the most efficient remedies, acting probably not only as a purgative, but also as an irritant to the worms, either by its immediate influence, or that of the acrid bile which it causes to flow. The slowness and uncertainty of its action, and its liability to salivate if too long retained in the bowels, render it proper either to follow or combine it with other cathartics, in order to ensure its purgative effect. When given alone, it should be followed, if it do not operate in six or seven hours, by a dose of castor oil or sulphate of magnesia. The cathartics with which it is most frequently combined are jalap, rhubarb, aloes, scammony, colocynth, and gamboge. It is often added in small quantities to purgative combinations, with a view to its influence on the liver.

In very large doses, calomel is supposed by some to act directly as a sedative, and with this view has been given in yellow and malignant bilious fevers, violent dysentery, malignant cholera, &c. The quantities which have been administered in such affections, with asserted impunity and even advantage, are

almost incredible. A common dose is one or two scruples, repeated every half hour, or hour, or less frequently, according to the circumstances of the case. We have had no experience in this mode of administering calomel.

It is sometimes used as an errhine in amaurosis, mixed with twice its weight of sugar, or other mild powder; and in the same combination is occasionally employed to remove specks and opacity of the cornea. For the latter purpose, Dupuytren recommended particularly the calomel prepared according to the plan of Mr. Jewell. M. Giraud-Teulon prefers using calomel in impalpable powder, without addition, and ascribes the remarkable success he has met with to his method of using it. (*Ann. de Thérap.*, 1867, p. 136.) Dr. Hennequin relates the case of a child, in which he applied calomel for a length of time for opacity of the cornea, without any effect, good or bad; but, having put the patient on the internal use of iodide of potassium, and returned to the insufflations which he had abandoned, he found violent inflammation of the eye produced, threatening even the loss of sight; and though the inflammation was subdued, and the specks disappeared with it, the remedy appears too hazardous for repetition. (*Journ. de Pharm. et de Chim.*, Nov. 1867, p. 325.) Calomel is also sometimes employed externally in herpetic and other eruptions, in the shape of an ointment.

The dose as an alterative, in functional derangement of the liver, is from half a grain to a grain every night, or every other night, followed in the morning, if the bowels are not opened, by a gentle saline laxative. When the stomach or bowels are very irritable, as in cholera and diarrhœa, from an eighth to a quarter of a grain may be given every hour or two, so as to amount to one or two grains in the course of the day. With a view to salivation, the dose is from half a grain to a grain three or four times a day, to be increased considerably in urgent cases. Sometimes, very minute doses, as the twelfth of a grain or less, given very frequently, so as to amount to the ordinary quantity in twenty-four hours, will operate more effectually as a sialagogue than larger doses. When large doses are given with this view, it is often necessary to combine them with opium. As a purgative, from five to fifteen grains or more may be exhibited. Calomel has the peculiarity that its cathartic action is not increased in proportion to the dose, and enormous quantities have been given with impunity. In yellow fever, tropical dysentery, &c., from twenty grains to a drachm have been given, and repeated at short intervals, without producing hypercatharsis; but this practice is justifiable only in cases of extreme urgency, in which the constitutional action of mercury as well as purgation is indicated. Even in very small doses of not more than one, two, or three grains, calomel purges some individuals briskly. In these persons, large doses, though they do not proportionably increase the evacuation, often occasion spasmodic pain in the stomach and bowels. For children larger doses are generally required in proportion than for adults. Not less than from three to six grains should be given as a purge to a child two or three years old; and this quantity often fails to act, unless assisted by castor oil or some other cathartic. Calomel may be given in pill made with gum arabic and syrup, or in powder mixed with syrup or molasses.

HYDRARGYRI CYANIDUM. *U. S.* Hydrargyri Cyanuretum. *U. S.* 1850. *Cyanide of Mercury. Cyanuret of Mercury. Bicyanide of Mercury. Prussiate of Mercury.*

"Take of Ferrocyanide of Potassium *five troyounces;* Sulphuric Acid *four troyounces and one hundred and twenty grains;* Red Oxide of Mercury, in fine powder, Water, each, *a sufficient quantity.* Dissolve the Ferrocyanide of Potassium in twenty fluidounces of Water, and add the solution to the Sulphuric Acid, previously diluted with ten fluidounces of Water, and contained in a glass retort. Distil the mixture nearly to dryness into a receiver, containing ten fluidounces of Water and three troyounces of Red Oxide of Mercury. Set aside two

fluidounces of the distilled liquid, and to the remainder add, with agitation, sufficient Red Oxide to destroy the odour of hydrocyanic acid. Then filter the solution, and, having added the reserved liquid, evaporate the whole in a dark place, in order that crystals may form. Lastly, dry the crystals, and keep them in a well-stopped bottle, protected from the light." *U. S.*

This is an entirely different formula from that of the Pharmacopœia of 1850, in which the ferrocyanide of iron and red oxide of mercury were brought together under circumstances favourable to reaction, with the result of producing bicyanide of mercury, the protoxide and sesquioxide of iron, and an undetermined compound of cyanogen. The present formula is based upon that of Winkler, given in the eleventh edition of the U. S. Dispensatory. Hydrocyanic acid is generated by the action of sulphuric acid on the ferrocyanide of potassium, and, being received in a vessel containing water and a portion of red oxide of mercury, reacts with the oxide, generating, by double decomposition, water, and bicyanide of mercury which is held in solution. The reaction takes place between one equivalent of the red oxide of mercury which is a binoxide, and two eqs. of hydrocyanic acid. The two eqs. of oxygen of the binoxide take two eqs. of hydrogen of the acid to form two eqs. of water, and the two liberated eqs. of cyanogen combine with the single liberated eq. of mercury to form the bicyanide of that metal. Sufficient red oxide of mercury is not used at first to saturate the whole of the hydrocyanic acid generated, because, should there happen to be any excess of the red oxide, there would be produced on evaporation, instead of the substance wanted, a peculiar salt composed of bicyanide and red oxide of mercury, which would crystallize in small acicular crystals. Hence, a portion of the water still containing uncombined hydrocyanic acid is set aside, to be added to the liquid in which the acid had been completely saturated by the addition of red oxide, and thus at least neutralize any oxide of mercury that might be present in it in excess A surplus of hydrocyanic acid would be of no disservice, except the loss of material incurred, as it is evaporated in the subsequent concentration.

Properties, &c. Cyanide of mercury is permanent in the air, and crystallizes in anhydrous right square prisms, which are sometimes transparent, but usually white and opaque. It has a disagreeable styptic taste. It is but sparingly soluble in alcohol, but dissolves readily in cold water, and much more abundantly in hot. When acted on by muriatic acid, hydrocyanic acid is evolved, recognisable by its odour, and bichloride of mercury is left, which is wholly volatilizable by heat. When heated it yields cyanogen, and a black matter is left containing globules of mercury.

In composition, according to the view taken in the U. S. Pharmacopœia, it is a bicyanide of mercury, consisting of one eq. of the metal 200, and two of cyanogen 52=252; its formula being $HgCy_2$. But with those who consider the eq. of mercury as 100, the salt is a protocyanide, with one eq. of each of its constituents (HgCy), and its combining number would be 126. The reader is already aware that the former opinion is still admitted in this work.

Cyanide of mercury acts on the animal economy as a potent poison. In medicinal doses it sometimes causes ptyalism, but does not produce epigastric pain like corrosive sublimate. It has been occasionally used as a remedy in syphilis; and in the treatment of that disease it is preferred by some practitioners to corrosive sublimate, on account of its not giving rise to pain, and not being decomposed by alkalies and organic substances. M. Desmartis, of Bordeaux, considers it superior to all the other preparations of mercury in the treatment of syphilitic complaints; particularly in cases in which the patients have suffered, for a long period, from obscure pains. The dose is from the sixteenth to the eighth of a grain, which should not be exceeded; as the medicine may meet with free muriatic acid in the stomach. B.

HYDRARGYRI IODIDUM RUBRUM. *U.S., Br. Red Iodide of Mercury. Biniodide of Mercury.*

"Take of Corrosive Chloride of Mercury *a troyounce;* Iodide of Potassium

a troyounce and one hundred and twenty grains; Distilled Water *a sufficient quantity.* Dissolve the Chloride of Mercury in a pint and a half, and the Iodide of Potassium in half a pint of Distilled Water, and mix the solutions. Collect the precipitate upon a filter, and, having washed it with Distilled Water, dry it with a gentle heat, and keep it in a well-stopped bottle." *U. S.*

"Take of Perchloride of Mercury *four ounces* [avoirdupois]; Iodide of Potassium *five ounces* [avoird.]; Boiling Distilled Water *four pints* [Imperial measure]. Dissolve the Perchloride of Mercury in three pints [Imp. meas.], and the Iodide of Potassium in the remainder of the Water, and mix the two solutions. When the temperature of the mixture has fallen to that of the atmosphere, decant the supernatant liquor from the precipitate, and, having collected the latter on a filter, wash it twice with cold distilled water, and dry it at a temperature not exceeding 212°." *Br.*

In the above processes for forming biniodide of mercury, which may be considered as identical, a double decomposition takes place between corrosive sublimate and iodide of potassium, resulting in the formation of chloride of potassium which remains in solution, and biniodide of mercury which precipitates. The precipitate is soluble in the reacting salts, and hence a loss of part of it is incurred by an excess of either. It is best, however, to have a slight excess of the iodide of potassium, which is furnished by the proportion taken in the formulas; as then the decomposition of the whole of the corrosive sublimate is ensured, and any contamination of the biniodide by it prevented. The late process of the Edinburgh College consisted in a combination of the ingredients by trituration in due proportion with the aid of alcohol; but, after the red powder was obtained, it was treated with a boiling solution of common salt, which dissolved the biniodide to the exclusion of any contaminating protiodide; and the solution, thus obtained, on cooling, deposited the pure biniodide in crystals.

Properties. Biniodide of mercury is a scarlet-red powder, of the sp. gr. 6·3, insoluble in water, sparingly soluble in alcohol, freely so in ether, and soluble in muriatic acid and in solutions of iodide of potassium, chloride of sodium, and many of the mercurial salts. As obtained by the late Edinburgh process, it is in splendid crimson acicular crystals. When heated it fuses readily into a yellow liquid, and sublimes in yellow rhombic scales, which become red on cooling. "It is entirely volatilized by a heat under redness." *Br.* Biniodide of mercury is a dimorphous substance, having a different crystalline form in its red and yellow states. According to Schiff, it is only in its yellow form that it is soluble in alcohol; and hence it is that, when separated by water from its alcoholic solution, it falls in this condition. (*Ann. der Chem. und Pharm.*, cix. 371.) It forms definite compounds with the iodides of the alkalifiable metals. The compound formed with iodide of potassium has been used as a medicine. (See *Iodohydrargyrate of Potassium*, in *Part* III.) "When digested with solution of soda it assumes a reddish-brown colour, and the fluid, cleared by filtration and mixed with solution of starch, gives a blue precipitate on being acidulated with nitric acid," showing that it is an iodide. Biniodide of mercury consists of one eq. of mercury 200, and two of iodine 252·6 = 452·6, and its formula is HgI_2. In the Br. Pharmacopœia, which recognises 100 as the eq. of mercury, it is considered as the neutral iodide, with the formula HgI. It combines with the protiodide, so as to form a yellow *sesquiodide*, represented by the formula $HgI + HgI_2$ or Hg_2I_3.

Medical Properties and Uses. Biniodide of mercury is a powerful irritant poison. It has been used in similar diseases with the protiodide, namely, in scrofula and syphilis, but is much more active. Dr. Fuller, physician to St. George's Hospital, London, has found it a valuable remedy in rheumatism, dependent on a syphilitic taint, having cured several cases in which corrosive sublimate had been given in vain. He also employed it with good results in two cases of epilepsy, dependent on injuries to the head, in which he suspected thickening of the dura mater, or deposit between it and the bone. (*Ranking's Abstract*, No. 25, p. 51.) The dose of this iodide is the sixteenth of a grain, gradually increased to the fourth, given in pill or dissolved in alcohol. A preferable mode of admi-

nistering it, is dissolved in a solution of iodide of potassium. This mode was adopted by Dr. Fuller, who attributes his success with the remedy, in great measure, to its having been given in this way. The preparation thus made is really a solution of iodohydrargyrate of potassium.

M. Cazenave considers biniodide of mercury as the best topical application in lupus. He applies it in thin layers, every six or eight days, to small portions of the ulcerated surface at a time, in the form of a caustic ointment, made of equal parts of the iodide, oil, and lard. The application produces severe pain, and gives rise to a sharp inflammation, which soon terminates, leaving the ulcer in an improved condition, with a tendency to cicatrize smoothly, and on a level with the surrounding skin. (*Ann. de Thérap.*, 1852, p. 175.)

HYDRARGYRI IODIDUM VIRIDE. *U. S.*, *Br.* HYDRARGYRI IODIDUM. *U. S.* 1850. *Green Iodide of Mercury. Protiodide of Mercury. Iodide of Mercury.*

"Take of Mercury *a troyounce;* Iodine *three hundred grains;* Stronger Alcohol *a sufficient quantity.* Mix the Mercury and Iodine in a mortar, and, having added half a fluidounce of Stronger Alcohol, triturate the mixture until the ingredients are thoroughly incorporated. Stir the mixture occasionally, and, at the end of two hours, triturate again, with considerable pressure, until it is nearly dry. Then rub it up with Stronger Alcohol, gradually added, until it is reduced to a uniform thin paste; and, having transferred this to a filter, wash it with Stronger Alcohol until the washings cease to produce a permanent cloudiness when dropped into a large quantity of water. Lastly, dry the Iodide in the dark with a gentle heat, and keep it in a well-stopped bottle, protected from the light." *U. S.*

"Take of Mercury, by weight, *one ounce* [avoirdupois]; Iodine *two hundred and seventy-eight grains;* Rectified Spirit *a sufficiency.* Rub the Iodine and Mercury in a porcelain mortar, occasionally moistening the mixture with a few drops of the Spirit, and continue the trituration until metallic globules are no longer visible, and the whole assumes a green colour. The product thus obtained should be dried in a dark room, on filtering paper, by simple exposure to the air, and preserved in an opaque bottle." *Br.*

This process for forming the protiodide of mercury is a case of simple combination, the alcohol facilitating the union by dissolving the iodine. It may also be prepared by precipitation, by adding a solution of iodide of potassium to one of nitrate of protoxide of mercury; but, as it is difficult to prepare the nitrate of the protoxide, without being mixed with some binitrate of deutoxide, the protiodide, when thus obtained, is apt to be contaminated with biniodide. M. Roland Seeger suggests double decomposition between protacetate of mercury and iodide of potassium. (*Am. Journ. of Pharm.*, May, 1859, p. 204.) M. Boutigny proposes to decompose calomel by iodide of potassium, and gives the following formula. Twenty-nine drachms of calomel are mixed with twenty of pulverized iodide of potassium in a glass mortar, and twelve ounces of boiling distilled water poured upon the mixture. After cooling the liquid is decanted, and the precipitate washed on a filter with distilled water, and dried in the shade. (See *Am. Journ. of Pharm.*, viii. 326.) This process did not succeed with Mr. Charles Bullock, of this city, when he used the reacting ingredients in quantities six times those recommended by M. Boutigny. Mr. John Canavan, of New York, ascribes the failure to insufficient trituration, which, to ensure complete reaction, must be long continued. If the reaction be imperfect, the water washes away not only chloride of potassium, but also iodide of potassium, holding in solution a part of the protiodide of mercury formed, which is ultimately decomposed into biniodide and metallic mercury. The experiments of Mr. J. M. Maisch, of this city, tend to confirm this view. He further found that a boiling temperature enables chloride of potassium to decompose the protiodide perceptibly, and infers that the use of cold water would give a purer product. He therefore con-

cludes that the process of Boutigny cannot be depended upon for giving a pure protiodide, and that we must fall back on the Pharmacopœia process. As prepared by the U. S. formula of 1850, it was liable to contain a little biniodide; but this is obviated in the present edition by the direction to wash it, near the close of the operation, with stronger alcohol. It is known to be free from the biniodide when the alcoholic washings produce no permanent cloudiness with a large quantity of water. Even thus purified, however, it generally contains a little metallic mercury, and, according to Dr. Squibb, a considerable proportion of the yellow or subiodide; but these are of little consequence compared with the biniodide, which should always be carefully sought for, and separated if found. (See Mr. Maisch's paper, *Am. Journ. of Pharm.*, Jan. 1857.)

From experiments by Mr. C. H. Wood, it appears that the green powder resulting from the British formula is a mixture of the protiodide with a large proportion of biniodide and metallic mercury. By continuing the trituration, the powders become more and more yellow, and at length have only a tinge of green. He infers that the pure protiodide is yellow, and that the green colour is owing to an admixture of the blue of the mercury with the yellow of the protiodide. (*Pharm. Journ.*, May, 1868, p. 503.)

Properties. Iodide of mercury is in the form of a greenish-yellow powder, insoluble in water, alcohol, and solution of chloride of sodium, and, according to the Br. Pharmacopœia, in ether also. Its sp. gr. is 7·75. When exposed to the light it is partially decomposed, and becomes of a dark-olive colour. If quickly and cautiously heated, it sublimes in red crystals which afterwards become yellow. "Gradually heated in a test tube, it yields a yellow sublimate, which, upon friction, or after cooling, becomes red, while globules of metallic mercury are left in the bottom of the tube." *Br.* It is a protiodide of mercury HgI, consisting of one eq. of mercury 200, and one of iodine 126·3 = 326·3. The Br. Pharmacopœia considers it a subiodide, with the formula Hg_2I; the eq. of mercury being 100.

Medical Properties and Uses. Iodide of mercury has been given in scrofula and scrofulous syphilis. The dose is a grain daily, gradually increased to three or four grains. It should never be given at the same time with iodide of potassium, which converts it immediately into biniodide and metallic mercury. (Mialhe, *Journ. de Pharm.*, 3e sér., iv. 36.) B.

HYDRARGYRI OXIDUM RUBRUM. *U. S.*, *Br.* Hydrargyri Nitrico-oxidum. *Lond.* *Red Oxide of Mercury. Red Precipitate.*

"Take of Mercury *thirty-six troyounces;* Nitric Acid *twenty-four troyounces;* Water *two pints.* Dissolve the Mercury, with the aid of a gentle heat, in the Acid and Water previously mixed, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel until red vapours cease to rise." *U. S.*

"Take of Mercury, by weight, *eight ounces* [avoirdupois]; Nitric Acid *four fluidounces and a half* [Imperial measure]; Water *two fluidounces* [Imp. meas.]. Dissolve half the Mercury in the Nitric Acid diluted with the Water, evaporate the solution to dryness, and with the dry salt thus obtained, triturate the remainder of the Mercury until the two are uniformly blended together Heat the mixture in a porcelain dish, with repeated stirring, until acid vapours cease to be evolved, and, when cold, enclose the product in a bottle." *Br.*

In these processes the mercury is first oxidized at the expense of a portion of the nitric acid, the remainder of which unites with the oxidized metal to form either nitrate of deutoxide of mercury, or a mixture of this with nitrate of the protoxide. The resulting mass when exposed to a strong heat is decomposed, giving out red nitrous fumes, and assuming successively a yellow, orange, and brilliant purple-red colour, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the protoxide of mercury, if any be present, is converted into deutoxide, while nitric oxide gas escapes, and becomes hyponitric acid vapour on contact with the air. The deutoxide of mercury is left behind; but in

general not quite free from the nitrate, which cannot be wholly decomposed by heat, without endangering the decomposition of the oxide itself, and the volatilization of the metal. The preparation is commonly called *red precipitate*. The name of *red oxide of mercury*, by which it is now designated in most of the Pharmacopœias, is appropriate, as nitrate of mercury exists in it merely as an accidental impurity; and there is no occasion to distinguish the preparation from the pure deutoxide obtained by calcining mercury, the latter not being officinal, and perhaps never employed.

In the preparation of this mercurial, various circumstances influence the nature of the product, and must be attended to, if we desire to procure the oxide with that fine bright orange-red colour, and shining scaly appearance, usually considered desirable. Among these circumstances is the condition of the nitrate of mercury submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in the officinal processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep-orange colour. Care must also be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. M. Payssé, who paid great attention to the manufacture of red precipitate, recommended 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé, to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more will be useless. It is not necessary that the salt should be removed from the vessel in which it is formed; and it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A matrass may be used with a large flat bottom, so that an extended surface may be exposed, and all parts heated equally. The metal and acid having been introduced, the matrass should be placed in a sand-bath, and covered with sand up to the neck. The solution of the mercury should be favoured by a gentle heat, which should afterwards be gradually increased till red vapours appear, then maintained as equably as possible till these vapours cease, and at last slightly elevated till oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the matrass, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide, and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the matrass being still allowed to remain in the sand-bath. These last precautions are said to be essential to the fine red colour of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more uniformly maintained. The direction in the British, taken from the late Ed. Pharmacopœia, to rub a portion of mercury with the nitrate before decomposing it, renders the process more economical; as the nitric acid, which would otherwise be dissipated, is thus employed in oxidizing an additional quantity of the metal.

As the process is ordinarily conducted in laboratories, the nitrate of mercury is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand, in the chamber of an oven or furnace, provided with a flue for the escape of the vapours. Each vessel may conveniently contain ten pounds of the nitrate. There is always loss in the operation thus conducted.

Under the name of *Hydrargyri Oxydum Rubrum*, the Dublin College formerly directed a preparation, called by the elder chemists *hydrargyrum præcipitatum per se*, or *precipitate per se*, and sometimes *calcined mercury*, made by exposing the metal to a heat near its boiling point, or about 600° F., in a matrass with a broad bottom and narrow mouth. The vapours rising were condensed in the upper part of the vessel; and a circulation was thus kept up within it, during which the mercury slowly combined with oxygen, being converted first into a black and then into a red powder. But the process was very slow, requiring several weeks for the complete oxidization of the metal; and, as the

product, which was pure deutoxide, had no peculiar virtues to recommend it over the oxide procured in the ordinary mode, it was properly discarded by the College. The oxide made in this way is in minute, sparkling, crystalline scales, of a deep-red colour, becoming still deeper by heat.

The same oxide of mercury, prepared by precipitation, was recognised in a former London Pharmacopœia by the name of *Hydrargyri Binoxidum*, or *binoxide of mercury*. It was made by adding solution of potassa in excess to a solution of bichloride of mercury, and differed from the preceding only in containing some water. It was an orange-red, impalpable powder, having the same properties essentially as the present officinal red oxide.*

Properties, &c. Red precipitate, well prepared, has a brilliant red colour, with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Dr. Barker found 1000 parts to take up 0·62 of the oxide. Dr. Christison found 1 part of the oxide to be dissolved by about 7000 parts of boiling water, and the solution to give a black precipitate with sulphuretted hydrogen. Tannic acid precipitates metallic mercury from its aqueous solution, especially when heated. (Bullock, *Proceed. of Am. Pharm. Assoc.*, 1858, p. 306.) It is insoluble in cold alcohol and ether. (*Ibid.*) Nitric and muriatic acids dissolve it without effervescence. It yields oxygen when heated, and at a red heat is decomposed and entirely dissipated. It is essentially the deutoxide (peroxide) of mercury, consisting of one equivalent of the metal 200, and two of oxygen 16 = 216, or, according to the Br. Pharmacopœia, the protoxide, consisting of one eq. of mercury 100, and one of oxygen 8 = 108; but, in its ordinary state, it always contains a minute proportion of nitric acid, probably in the state of subnitrate. According to Brande, when rubbed and washed

* *Yellow Amorphous Oxide of Mercury.* This preparation differs from the red oxide in being made by precipitation. Great care should be observed to procure it perfectly pure. Dr. Hoffmann recommends the following method. A solution of corrosive sublimate is to be treated with solution of potassa in slight excess. After the complete deposition of the precipitated oxide, the supernatant liquid is to be decanted, and the precipitate thoroughly washed with distilled water, and dried with a gentle heat in the absence of daylight. Thus prepared, the oxide is of a yellow colour similar to that of the yelk of eggs, and is a completely amorphous powder, exhibiting no evidence of crystalline particles even under the microscope. In consequence of its different state of aggregation, it presents some peculiarities in its chemical relations; being much more quickly acted on by reagents than the red oxide. Thus, oxalic acid, which acts on the red oxide only with the aid of heat, immediately combines with the yellow oxide at ordinary temperatures, producing the white oxalate; and while the latter oxide, in contact with chlorine, gives up oxygen to that element, forming hypochloric acid and calomel, the former exercises scarcely any influence on the gas at common temperatures. The attention recently paid to the yellow oxide is owing to its peculiar applicability to the local treatment of diseases of the eye, in consequence of its amorphous character. Mr. B. Squire, of England, was the first to notice publicly this use of the oxide (see *Pharm. Journ.*, 2d series, vi. 512); but a subsequent communication from Drs. Pagenstecher and Hoffmann, of Wiesbaden, in the "Ophthalmic Review" (July, 1865), has given greater importance to the subject, as adding the weight of experince to that of theory.

The red oxide, however carefully it may be triturated, even though in a perfectly impalpable state, still shows under the microscope crystalline particles, which, in contact with the conjunctiva, cause more or less irritation; and it can, therefore, be readily understood that, in the ordinary mode of preparing it for use as an ointment, it may sometimes be productive of serious annoyance. From this objection the yellow oxide is entirely exempt; and its consequent superiority for the purpose of an eye-ointment was fully determined by Dr. Pagenstecher, who was induced to employ it at the recommendation of Dr. Hoffmann.

But the character of the unctuous vehicle is of much importance. Without being so liquid as to allow the powder to subside, it must yet be of so soft a consistence as to melt at the heat of the body, and thus, when introduced into the eye, to spread equably over the surface. It should, moreover, be as far as possible chemically indifferent to the oxide, and, while perfectly bland in its proper state, should not be liable to become irritating by rancidity. After many trials, the best vehicle was found to be either *cold cream*, consisting of spermaceti, wax, and almond oil, without the rose-water, or a mixture of butter of cacao and almond oil. The oil employed should be as fresh as possible; and the proportion of the oxide to the unctuous vehicle recommended is a drachm of the former to an ounce of the latter. (*Pharm. Journ.*, 2d ser., vii. 324.)—*Note to the thirteenth edition.*

with a solution of potassa, edulcorated with distilled water, and carefully dried, it may be regarded as nearly pure deutoxide. It is said to be sometimes adulterated with brickdust, red lead, &c.; but these may be readily detected, as the oxide of mercury is wholly dissipated if thrown upon red-hot iron. The disengagement of red vapours, when it is heated, indicates the presence of nitrate of mercury. The same or some other saline impurity would be indicated, should water, in which the oxide has been boiled, afford a precipitate with lime-water.

Medical Properties and Uses. This preparation is too harsh and irregular in its operation for internal use; but is much employed externally as a stimulant and escharotic either in the state of powder or of ointment. In the former state it is sprinkled on the surface of chancres, and indolent, flabby, or fungous ulcers; and, mixed with 8 or 10 parts of finely powdered sugar, is sometimes blown into the eye to remove opacity of the cornea. The powder should be finely levigated. The ointment is officinal.*

* *Black Oxide of Mercury. Oxidum Hydrargyri Nigrum.* U. S. 1850. Though discarded from the Pharmacopœia, this preparation still has claims to notice. It was obtained by the following officinal process.

"Take of Mild Chloride of Mercury [calomel], Potassa, each, *four ounces;* Water *a pint.* Dissolve the Potassa in the Water, and, when the dregs have subsided, pour off the clear solution. To this add the Mild Chloride of Mercury, and stir them constantly together till the Black Oxide is formed. Having poured off the supernatant liquor, wash the Black Oxide with distilled water, and dry it with a gentle heat." *U. S.* 1850.

The object of this process is to obtain the protoxide or black oxide of mercury, which was at one time believed to be the active constituent of those preparations in which the metal is minutely divided by trituration. The calomel is completely decomposed by the solution of potassa; its chlorine uniting with potassium to form chloride of potassium, which remains in solution, and the mercury with the oxygen of the potassa to form protoxide of mercury, which subsides. More potassa is employed than by calculation would seem to be requisite; but it has been ascertained by experiment that a considerable excess is necessary for the complete decomposition of the calomel. The use of the officinal solution of potassa is preferable, on the score of economy, to that of a solution extemporaneously prepared from the caustic alkali. In order to ensure the success of the process, the calomel, very finely levigated, should be rubbed quickly with the alkaline solution in a mortar; and the resulting oxide should be dried in the dark with a very gentle heat, as it is decomposed by the agency both of light and of an elevated temperature. For the same reason it should be preserved in an opaque bottle. This mode of preparing the black oxide of mercury originated with Mr. Donovan.

The oxide may also be prepared by decomposing a solution of nitrate of protoxide of mercury by solution of potassa. This nitrate may be obtained by treating 20 parts of mercury with 18 parts of nitric acid of 25° Baumé, adding, when nitrous vapours cease to rise, 10 parts of warm distilled water, boiling for a short time, decanting the clear liquor, and setting it aside to crystallize. The mother-waters by evaporation will furnish a new product of crystals of nitrate of protoxide. (Ratier, *Pharm. Franç.*) The London College formerly prepared this oxide by decomposing calomel with lime-water; but it is extremely difficult to effect a complete decomposition in this way, and the preparation was consequently almost always mixed with calomel. The preparation, officinal in a former Dublin Pharmacopœia under the name of *Pulvis Hydrargyri Cinereus*, made by adding carbonate of ammonia to a solution of mercury in heated nitric acid, was a mixture of subnitrate of mercury and ammonia with protoxide of mercury. Both the London and Dublin Colleges abandoned the protoxide in the latest editions of their Pharmacopœias.

Properties, &c. As first prepared, this oxide is greenish-black; but, as found in the shops, it is almost always of an olive colour. It is inodorous, tasteless, and said to be insoluble in water and alkaline solutions; but, according to Mr. Charles Bullock, it is appreciably soluble in cold water, and to a greater extent in boiling water, but is insoluble in cold alcohol and ether. (*Proceedings of the Am. Pharm. Assoc.*, 1858, p. 302.) It consists of one eq. of mercury 200, and one of oxygen 8 = 208. On exposure to light or heat it is decomposed, one part assuming the metallic state, in consequence of the loss of its oxygen, which converts another part into the deutoxide. The preparation, therefore, becomes a mixture of the protoxide, deutoxide, and metallic mercury, with which calomel is sometimes associated, in consequence of the incomplete decomposition of that employed in the process. By a strong heat it is completely dissipated, and metallic globules are sublimed. When pure it is soluble in acetic and nitric acids, and entirely insoluble in muriatic acid, which forms with it water and calomel. If it contain the deutoxide, this will be dissolved by muriatic acid, and may be detected in the solution by the production of a white precipitate with water of ammonia, and a yellow one with solution of potassa. Calomel, if present, may be discovered by boiling the powder with a solution of potassa, thus forming chloride of potassium, which, when the solution is saturated with nitric acid, will afford a white precipitate of chloride of silver on the addition of nitrate of silver. (*Phillips.*)

Off. Prep. Hydrargyri Cyanidum, *U. S.;* Unguentum Hydrargyri Oxidi Rubri. W

HYDRARGYRI SULPHAS. *Br. Sulphate of Mercury.*

"Take of Mercury, by weight, *twenty ounces* [avoirdupois]; Sulphuric Acid *twelve fluidounces* [Imperial measure]. Heat the Mercury with the Sulphuric Acid in a porcelain vessel, stirring constantly, until the metal disappears, then continue the heat until a dry white salt remains." *Br.*

Mercury is not acted on by cold sulphuric acid; but, when boiled with an excess of this acid to dryness, it is deutoxidized at the expense of part of the acid, sulphurous acid being copiously evolved; and the deutoxide formed unites with the undecomposed portion of the sulphuric acid, so as to form bisulphate of deutoxide of mercury, which is the officinal sulphate.

Sulphate of mercury, as obtained by a separate formula, is peculiar to the British Pharmacopœia; but it is formed as the first step of the processes of the U. S. Pharmacopœia for preparing corrosive sublimate, calomel, and turpeth mineral. The adoption of a separate formula and distinct officinal name for this salt is certainly a convenience; as it obviates the necessity of repeating the directions for obtaining the same substance in several formulas. On account of its various uses, it requires to be made on a large scale by the manufacturing chemist; and the process is generally performed in a cast-iron vessel, which should be conveniently arranged for the escape and decomposition of the sulphurous acid fumes, which otherwise become a serious nuisance to the neighbourhood. The best way to effect this purpose is to allow them to pass off through a very lofty chimney, mixed with abundance of coal smoke.

Properties, &c. Sulphate of mercury is in the form of a white crystalline powder, becoming yellow by the affusion of water, and entirely volatilizable by heat. It consists of two eqs. of acid 80 and one of deutoxide of mercury 216 = 296; or, according to the Br. Pharmacopœia, of one eq. of acid 40 and one of protoxide of mercury 108 = 148. It has no medical uses.

Off. Prep. Hydrargyri Perchloridum, *Br.;* Hydrargyri Subchloridum, *Br.* B.

HYDRARGYRI SULPHAS FLAVA. *U. S. Yellow Sulphate of Mercury. Turpeth Mineral.*

"Take of Mercury *four troyounces;* Sulphuric Acid *six troyounces.* Mix them in a glass vessel, and boil, by means of a sand-bath, until a dry white mass remains. Rub this into powder, and throw it into boiling water. Pour off the supernatant liquor, wash the yellow precipitate repeatedly with hot water, and dry it." *U. S.*

By referring to the articles on corrosive sublimate and calomel, it will be found that the peculiar salt which is generated by boiling sulphuric acid with mercury to dryness, is directed to be made as the first step for obtaining these chlorides; and here the same salt is again directed to be formed in preparing turpeth mineral. We have already stated that this salt is the bisulphate of deutoxide of mercury. When thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is the turpeth mineral. According to Berzelius, turpeth mineral is a basic sesquisulphate

Medical Properties and Uses. The black oxide is alterative, sialagogue, and purgative. It may be employed for the same purposes as calomel, over which, however, it has not in our hands exhibited any superiority, while, from the occasional presence of the deutoxide, it must be liable to operate harshly. Dr. B. H. Coates, of this city, informed us some years since that he used it habitually as a mercurial, and found it to answer an excellent purpose. The idea under which it was introduced into use, that it was the basis of the blue pill, is erroneous. Made into an ointment with lard, according to the process of Donovan, it may be applied externally with good effect in bringing the system under the mercurial influence. (See *Unguentum Hydrargyri.*) Its dose as an alterative is one-fourth or half of a grain daily, as a sialagogue from one to three grains two or three times a day, given in the form of pill. It was used by Mr. Abernethy for mercurial fumigation; the patient being placed, covered with under-garments, in a vapour-bath, and exposed for 15 or 20 minutes to the vapours arising from two drachms of the oxide, put upon heated iron within the bath. W.

of deutoxide of mercury, and the supernatant solution contains a supersulphate, consisting of six eqs. of acid and one of base. The same composition for turpeth mineral is given by Gay-Lussac; and its accuracy was verified by Sir Robert Kane of Dublin. (See *Pharm. Journ.*, August, 1842.) The composition above given of turpeth mineral implies the decomposition of four eqs. of bisulphate of deutoxide, and the manner in which the reaction takes place is shown by the following equation; $4(HgO_2,2SO_3) =$ turpeth mineral, $3HgO_2,2SO_3$, and supersulphate of mercury, $HgO_2,6SO_3$.

Properties, &c. Yellow sulphate of mercury is a lemon-yellow powder, of a somewhat acrid taste. It dissolves in 2000 parts of cold, and about 600 of boiling water. Exposed to a moderate heat, it becomes first red and afterwards brownish-red, but regains its original colour on cooling. (*Barker.*) At a red heat it is decomposed and dissipated, sulphurous acid being evolved, and metallic globules sublimed. It was originally called *turpeth* mineral, from its resemblance in colour to the root of *Ipomæa Turpethum*.

Medical Properties and Uses. Turpeth mineral is alterative, and powerfully emetic and errhine. As an alterative, it has been given in leprous disorders and glandular obstructions. It has been usefully employed as an emetic, repeated every few days, in chronic enlargement of the testicle. It operates with great promptness, and sometimes excites ptyalism. Dr. Hubbard, of Maine, considers it a valuable emetic, in cases requiring an equalizing and revulsive effect, apart from any cathartic operation, which he has never known it to produce. He recommends it highly as an emetic in croup, on the ground of its promptness and certainty, and of its not producing catharsis, or the prostration caused by antimony. The dose for a child two years old is two or three grains, repeated in fifteen minutes, if it should not operate. As an errhine, it has been used with benefit in chronic ophthalmia; but it sometimes produces salivation when thus employed. The dose as an alterative is from a quarter to half a grain; as an emetic from two to five grains. When employed as an errhine, one grain may be mixed with five of starch or powdered liquorice root.

Turpeth mineral, in an overdose, acts as a poison. A case of death in a boy aged sixteen, caused by swallowing a drachm, is reported by Dr. Letheby in the *London Medical Gazette* for March, 1847. B.

HYDRARGYRI SULPHURETUM RUBRUM. *U.S.* Cinnabaris. *Ed. Red Sulphuret of Mercury. Bisulphuret of Mercury. Cinnabar.*

"Take of Mercury *forty troyounces;* Sulphur *eight troyounces.* To the Sulphur, previously melted, gradually add the Mercury, with constant stirring, and continue the heat until the mass begins to swell. Then remove the vessel from the fire, and cover it closely to prevent the contents from inflaming. When the mass is cold, rub it into powder, and sublime." *U. S.*

This preparation has been discarded, we think somewhat prematurely, by the British Council.

Mercury and sulphur, when heated together, unite with great energy, and a product is obtained, which by sublimation becomes the red or bisulphuret of mercury. In order to render the combination more prompt, the sulphur is first melted; and the addition of the mercury should be made gradually, while the mixture is constantly stirred. Dr. Barker recommends the addition of the metal by straining it upon the melted sulphur through a linen cloth, whereby it falls in a minutely divided state. When the temperature has arrived at a certain point, the combination takes place suddenly with a slight explosion, attended with the inflammation of the sulphur, which must be extinguished by covering the vessel. A black mass will thus be formed, containing generally an excess of sulphur, which, before the sublimation is performed, should be got rid of by gently heating the matter, reduced to powder, on a sand-bath. The sublimation is best performed, on a small scale, in a loosely stopped glass matrass, which should be placed in a crucible containing sand, and, thus arranged, exposed to a red heat. The equivalent quantities for forming this sulphuret are 32 of sulphur and 200 of mercury.

Preparation on the Large Scale. Cinnabar is seldom prepared on a small scale, being made in large quantities for the purposes of the arts. In Holland, where it is principally manufactured, the sulphur is melted in a cast-iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. The larger the quantity of the materials employed in one operation, the finer will be the tint of the product. It is also important in the manufacture to use the materials pure, and to drive off any uncombined sulphur which may exist in the mass, before submitting it to sublimation.

Properties, &c. Red sulphuret of mercury is in the form of heavy, brilliant, crystalline masses, of a deep-red colour and fibrous texture. It is inodorous and tasteless, and insoluble in water and alcohol. It is not acted on by nitric, muriatic, or cold sulphuric acid, or by solutions of the caustic alkalies; but is soluble in nitromuriatic acid, on account of the free chlorine which the mixed acid contains. When heated with potassa, it yields globules of mercury. In the open air it is decomposed by heat, the sulphur becoming sulphurous acid, and the mercury being volatilized. In close vessels at a red heat it sublimes without decomposition, and condenses in a mass, composed of a multitude of small needles. When duly levigated, it furnishes a brilliant red powder, which is the paint called *vermilion.* The same compound occurs native, being the sole ore from which mercury is extracted. The preparation, if purchased in powder, should be carefully examined; as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, acetic acid, digested with it, will yield a yellow precipitate (iodide of lead) with iodide of potassium. Dragon's blood may be detected by alcohol, which will take up the colouring matter of that substance, if present; and, if chalk be mixed with it, effervescence will be excited on the addition of an acid. This sulphuret consists of one eq. of mercury 200, and two of sulphur 32=232.

Medical Properties and Uses. Cinnabar was formerly thought to be alterative and anthelmintic, but is at present seldom given internally. It is sometimes employed by fumigation, as a rapid sialagogue, in venereal ulcers of the nose and throat, in cases in which it is important to bring the system under the influence of mercury in the shortest possible time. The dose internally is from ten grains to half a drachm, in the form of electuary or bolus. When used by fumigation, half a drachm may be thrown on a red-hot iron, and the fumes inhaled as they arise. These consist of sulphurous acid gas and mercurial vapour, the former of which must prove highly irritating to the patient's lungs. A better substance for mercurial fumigation is the black oxide of mercury.* B.

* *Black Sulphuret of Mercury. Ethiops Mineral. Hydrargyri Sulphuretum Nigrum.* Though very properly discarded from the Pharmacopœias, this has too long occupied a place in the catalogue of the Materia Medica to be passed over entirely without notice. The following was the formula of the U. S. Pharmacopœia of 1850, for its preparation.

"Take of Mercury, Sulphur, each, *a pound.* Rub them together till all the globules disappear." *U. S.*

Mercury and sulphur have a strong affinity for each other, as is shown by the fact, that, when they are triturated together in quantities, the mixture grows hot, cakes, and exhales a sulphurous odour. During the trituration, the mixture should be sprinkled from time to time with a little water or alcohol, to prevent the dust from rising, which exposes the operator to serious inconvenience. When rubbed together in equal weights, as directed in the formula, they are supposed to unite chemically; but the proportion of sulphur is much greater than is necessary to form a definite compound. Only two sulphurets of mercury have been admitted by chemists generally, the protosulphuret, and bisulphuret or cinnabar; but the quantity of sulphur directed in the process is much more than sufficient to form even the latter. It is still undetermined what is the exact nature of the officinal black sulphuret, or *ethiops mineral.* Mr. Brande, from his experiments, considers it to be the bisulphuret mixed with sulphur. Thus, he found that, when boiled repeatedly in solution of potassa, sulphur was dissolved, and a black insoluble powder was left, which sublimed without decomposition, and yielded a substance having all the characters of cinnabar.

Ethiops mineral is sometimes obtained by melting sulphur in a crucible, and adding to it an equal weight of mercury; but, when thus prepared, the sulphur is apt to become

HYDRARGYRUM AMMONIATUM. *U. S.*, *Br.* HYDRARGYRI PRECIPITATUM ALBUM. *Ed.* HYDRARGYRI AMMONIO-CHLORIDUM. *Lond.* *Ammoniated Mercury. White Precipitate.*

"Take of Corrosive Chloride of Mercury *six troyounces;* Water of Ammonia *eight fluidounces;* Distilled Water *eight pints.* Dissolve the Corrosive Chloride of Mercury in the Distilled Water, with the aid of heat, and to the solution, when cold, add the Water of Ammonia, frequently stirring. Wash the precipitate with water until the washings become nearly tasteless, and dry it." *U. S.*

"Take of Perchloride of Mercury *three ounces* [avoirdupois]; Solution of Ammonia *four fluidounces;* Distilled Water *three pints* [Imperial measure]. Dissolve the Perchloride of Mercury in the Water with the aid of a moderate heat; mix the Solution with the Ammonia, constantly stirring; collect the precipitate on a filter, and wash it well with cold Distilled Water until the liquid which passes through ceases to give a precipitate when dropped into a solution of nitrate of silver acidulated with nitric acid. Lastly, dry the product at a temperature not exceeding 212°." *Br.*

The Pharmacopœias now agree in obtaining white precipitate by precipitating a solution of corrosive sublimate by ammonia. When ammonia, in slight excess, is added to a cold solution of corrosive sublimate, muriate of ammonia is formed in solution, and the white precipitate of the Pharmacopœias is thrown down. The precipitate is washed, according to the U. S. formula, until the washings become nearly tasteless, according to the British, with greater precision, until they cease to give evidence of the presence of a chloride by producing a precipitate with nitrate of silver acidulated with nitric acid. The matter washed away is muriate of ammonia and the excess of ammonia employed; and hence the washings, agreeably to the directions of the British formula, are tested with an acid solution of nitrate of silver. According to Sir Robert Kane, white precipitate has a composition corresponding to one eq. of bichloride of mercury, united with one eq. of a compound consisting of one eq. of mercury combined with two eqs. of a hypothetical body represented by one eq. of ammonia *minus* one eq. of hydrogen. This hypothetical body, represented by NH_2, he has named *amidogen*, the *amide* of some chemists. The reaction may be supposed to take place between four eqs. of ammonia and two of bichloride of mercury. Two eqs. of ammonia by parting with one eq., each, of hydrogen, become two eqs. of amidogen, which unite with the mercury of one eq. of the bichloride to form the binamide of mercury; while the two liberated eqs. of hydrogen of the ammonia combine with the two liberated eqs. of chlorine of the bichloride, forming two eqs. of muriatic acid; and the binamide then unites with the second eq. of the bichloride to produce the insoluble chloro-amide of mercury or white precipitate, which falls. The two eqs. of muriatic acid combine with a like number of ammonia, and remain in solution as two eqs. of muriate of ammonia. In symbols, the reaction is thus denoted: $4NH_3$ and $2HgCl_2 = Hg_2NH_2 + HgCl_2$ and $2(NH_3$,

acidified, and the preparation to acquire an activity which does not belong to it when obtained by trituration.

Properties, &c. Black sulphuret of mercury is a heavy, tasteless, insoluble powder. When exposed to heat, it becomes of a dark-violet colour, emits the excess of sulphur in sulphurous acid fumes, and sublimes in brilliant red needles without residue. If charcoal be present it will remain behind. When well prepared, no globules of mercury are discernible in it when viewed with a magnifier; and, if rubbed on a gold ring, it should not communicate a white stain. Ivory-black is detected in it by throwing a small portion on red-hot iron, when a white matter (phosphate of lime) will be left behind. Adulteration by sulphuret of antimony is shown, if muriatic acid, boiled on a portion of the powder, acquires the property of causing a precipitate of oxychloride of antimony when added to water. According to the views of Mr. Brande, ethiops mineral consists of one eq. of bisulphuret of mercury, mixed with about ten and a half eqs. of sulphur in excess.

Medical Properties. Ethiops mineral is supposed to be alterative, and as such has been sometimes prescribed in glandular affections and cutaneous diseases, especially in the cases of scrofulous children, to which, from the mildness of its operation, it has been thought to be well adapted. The dose generally given was from five to thirty grains, repeated several times a day; but it has often been administered in much larger doses, without producing any obvious impression on the system. At present it is very little used as a medicine. B.

HCl). For an account of ammonium, see *page* 103. The analysis of Kane agrees virtually with those of Guibourt and Hennell.

Properties, &c. Ammoniated mercury is in powder or pulverulent masses, perfectly white, insoluble in water, alcohol, and ether, decomposed by boiling water, and having a taste at first earthy, and afterwards metallic. It dissolves without effervescence in muriatic acid. When heated with a solution of caustic potassa, it yields ammonia and becomes yellow. Exposed to a strong heat it is entirely dissipated, and resolved into nitrogen, ammonia, and protochloride of mercury. Adulteration with white lead, chalk, or sulphate of lime may be detected by exposing a sample to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charry residue will be obtained on the application of heat. Lead or starch may be found by digesting it with acetic acid, and testing the acetic solution with the compound solution of iodine, which will give a yellow precipitate if lead, and a blue one if starch be present. The absence of protoxide of mercury is shown by its not being blackened when rubbed with lime-water. Ammoniated mercury is used only as an external application.

A variety of white precipitate, distinguished as being fusible, was formerly officinal, and is said to be still occasionally made by the manufacturing chemist, from its greater cheapness and facility of preparation, and to be still found in commerce. It was made by precipitating a mixture of equal parts of sal ammoniac and corrosive sublimate in solution by one of the fixed alkalies. It differs somewhat from the present officinal preparation in composition, containing only half the proportion of mercury, and in properties by fusing before being volatilized, while the genuine article sublimes without melting. It is said to produce an ointment more translucent and less beautifully white than the genuine, and more apt to become yellow on being kept. (Mr. J. Borland, *Pharm. Journ.*, Dec. 1867, p. 262.)

Ammoniated mercury has been swallowed by mistake. It is highly poisonous, producing gastric pain, nausea, and purging. A case of recovery, after taking what was estimated to be half a drachm, is reported in the *London Lancet* for July 4, 1857. The remedies employed were an emetic of sulphate of zinc, and milk to allay the gastro-intestinal irritation.

Off. Prep. Unguentum Hydrargyri Ammoniati. B.

HYDRARGYRUM CUM CRETA. *U. S.*, *Br.* *Mercury with Chalk. Gray Powder.*

"Take of Mercury *three troyounces;* Prepared Chalk *five troyounces.* Rub them together until the globules cease to be visible, and the mixture acquires a uniform gray colour." *U. S.*

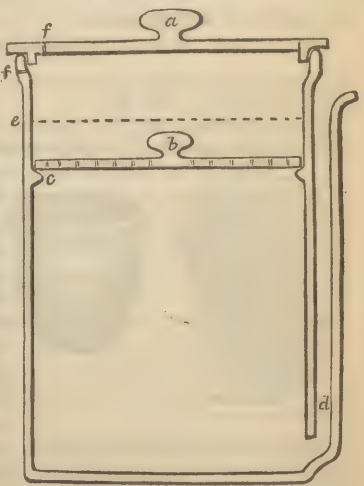
"Take of Mercury, by weight, *one ounce;* Prepared Chalk *two ounces.* Rub the Mercury and Chalk in a porcelain mortar until metallic globules cease to be visible to the naked eye, and the mixture acquires a uniform gray colour." *Br.*

When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic lustre, and becomes a blackish or dark-gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens; and the mercury is said to be extinguished. It was formerly thought that the metal was oxidized in the process. At present, the change is generally ascribed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury, in which the metal is extinguished by trituration, a very small portion is converted into protoxide, while by far the greater part remains in the metallic state.

Mercury with chalk is a smooth grayish powder, insoluble in water. Globules of mercury can generally be seen in it with the aid of a microscope; as the metal can scarcely be completely extinguished with chalk alone by any length of trituration. Mr. Jacob Bell found that, by powerfully pressing it, a considerable quantity of metal was separated in the form of globules. Mr

Phillips states that the extinguishment of the mercury is greatly accelerated by the addition of a little water. Dr. Stewart, of Baltimore, proposed the following process, by which he stated that the preparation might be completed in a short time, so that no globules should be visible with a powerful lens. Three ounces of mercury and six ounces of resin are to be rubbed together for three hours; five ounces of chalk are to be added, and the trituration continued for an hour; the mixture is then to be heated with alcohol so as to dissolve the resin; and the remaining powder is to be dried on bibulous paper, and well rubbed in a mortar. (*Am. Journ. of Pharm.*, xv. 162.) But Professor Procter has shown that the preparation thus made contains deutoxide of mercury, and is, therefore, injuriously harsh in its operation. (*Ibid.*, xxii. 113.) It is said that the precipitated black oxide is sometimes added with a view to save time in the trituration; but this must be considered as an adulteration, until it can be shown that the same oxide exists, in the same proportion, in the preparation made according to the officinal directions. Dr. Ed. Jenner Coxe, of New Orleans, found that the extinguishment of the mercury may be effected much more speedily than in the ordinary manner, by putting the ingredients into a quart bottle, to be well corked, and kept in constant agitation till the object is attained. A portion of the chalk may be thus shaken with the metal until no globules can be seen, and the process completed by trituration with the remainder of the chalk in a mortar. This mode of proceeding was suggested to Dr. Coxe by Mr. W. Hewson, of Augusta, Ga. (*Ibid.*, xxii. 317.) Dr. Squibb, having ascertained that the preparation cannot be satisfactorily made in this way on a large scale (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 424), has invented a machine for accomplishing the same object, by which the requisite motion is imparted to the materials contained in two large bottles, and which is said to answer the purpose well. By means of this apparatus, Dr. Squibb prepares mercury with chalk on a large scale, mixing the materials in the officinal proportions, but aiding the extinguishment of the metal by adding about one-seventh of its weight of honey, and making the chalk into a paste with water before putting it into the bottles. (*Ibid.*, 1859, p. 359.) It has been shown that the preparation thus made resists oxidation most effectually; owing probably to the presence of saccharine matter. (I. P. Remington, *Am. Journ. of Pharm.*, Jan. 1869.) As found in commerce, mercury with chalk, instead of being the mild preparation intended, sometimes acts very harshly, causing vomiting, gastric pains, &c. This has been ascribed to the presence of antimony or arsenic, which, however, must be rare; and the ordinary cause of the harshness is no doubt peroxide of mercury, produced in minute proportion either during the trituration, or by the spontaneous change which occurs with time; the protoxide being deutoxidized by the influence of light. The only sure method to guard against such results is carefully to test the preparation before dispensing it. If the mercury contained in it be volatilized by heat, and the remaining chalk be dissolved by dilute acetic acid, the solution should not be coloured by sulphuretted hydrogen. The presence of any probable metallic impurity may be detected in this way. To detect peroxide of mercury, a portion of the powder may be treated with dilute muriatic acid with a moderate heat, and the solution tested by protochloride of tin, which, if there be any peroxide present, will cause a precipitation of metallic mercury as a black powder.

Medical Properties and Uses. Mercury with chalk is a very mild mercurial, similar in its properties to the blue pill, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children attended with deficient biliary secretion, indicated by white or clay-coloured stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in diarrhœa. Eight grains of the U. S. preparation contain three grains of mercury. The dose is from five grains to half a drachm twice a day. Two or three grains is the dose for a child. It should not be given in pill with substances which become hard on keeping; as the contraction of the mass presses together the particles of mercury, which, in time, appear in globules in the interior of the pill. W.



INFUSA.

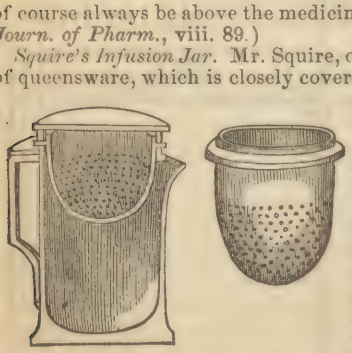
Infusions.

These are aqueous solutions obtained by treating with water, without the aid of ebullition, vegetable products only partially soluble in that liquid. The water employed may be hot or cold, according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance, and macerating in a lightly closed vessel till the liquid cools. The soluble principles are thus extracted more rapidly, and, as a general rule, in a larger proportion than at a lower temperature. Some substances, moreover, are dissolved in this manner, which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable; and this may be effected by placing the vessel near the fire. Cold water is preferred when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case; and, in warm weather, there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a strong infusion is required, the *process of percolation* may be advantageously resorted to. (See *pages* 931 and 942.) The water employed should be free from saline impurities, which frequently produce precipitates and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to that of pumps or springs.

The substance to be acted on should be sliced or bruised, or in the state of powder; but, unless when percolation is employed, this last condition is seldom requisite, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases, it is sufficient to strain through fine linen or muslin. When percolation is resorted to, the substance should be more or less finely powdered. Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Mr. Brande suggests the use of clean metallic vessels, which, when finely polished, retain the heat for a longer time; but they are also more liable to chemical alteration, and may sometimes injuriously affect the preparation. Vessels of block-tin are generally well adapted for the purpose.*

* *Alsop's Infusion Jar.* This presents a very neat and effectual method of making the hot infusions. It consists of an earthenware mug, represented in the marginal figure, with a spout (*d*) proceeding from the bottom, and placed closely to the side of the vessel to prevent fracture; a perforated plate or diaphragm (*b*), supported on a ledge (*c*) at about one-quarter or one-third of the height of the vessel from the top; and a lid (*a*), which may be fastened on by a string through holes (*ff*). The material to be submitted to infusion is placed on the perforated plate, and the hot water poured in so as to cover it, the vessel having been previously warmed so as not to chill the liquid. As the water becomes impregnated, it acquires an increased specific gravity, and sinks to the bottom, its place being supplied by the unsaturated portion; and this circulation goes on until the whole of the soluble matter is extracted. In order to maintain a due warmth, the vessel may be placed upon a stove or an iron plate near the fire. The advantage of the process is that the material is subjected to the solvent power of the least impregnated portion of the menstruum. Such jars may now be had in Philadelphia. In order that the vessel may be adapted for the preparation of different quantities of infusions, it will be proper to have ledges arranged within at different heights, so that the diaphragm may be supported at any desirable point. The surface of the liquid (*e*) should

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in families, and the propriety of their introduction into the Pharmacopœia has been doubted; but it is desirable to have certain fixed standards for the regulation of the medical practitioner; and it is sometimes convenient to direct infusions from the apothecary, for whose guidance officinal formulas are necessary. Physicians would, indeed, find their advantage in more frequently directing them from the shops, instead of leaving their preparation to the carelessness or want of skill of attendants upon the sick. For a mode of preserving infusions, the reader is referred to the introductory observations, *page* 936. By making very concentrated infusions, as suggested by Mr. Donovan, with a mixture of three parts of water and one of alcohol, they may be long kept, and when used can be diluted with water to the proper strength. Thus, if made four times as strong as the officinal infusion, they may be diluted with three measures of water. The proportion of alcohol would thus be very small; but it might still be medically injurious; and infusions should not be prepared in this way unless with the cognizance of the prescriber.



Mr. Battley, of London, has introduced a new set of preparations, which he calls *inspissated infusions*, the advantages of which are that the virtues are extracted by cold water, are not injured by heat used in the evaporation, are in a concentrated state, and are not impaired by time. To prepare them he macerates the material, coarsely powdered, bruised, or finely sliced, in twice its weight of cold distilled water, pressing the solid matter into the liquid repeatedly by a rammer or the hand; then allows the liquid to drain out, or expresses it in the case of highly absorbent substances; and repeats the process, with an amount of water equal to that which has been separated, until the strength is exhausted. Four or six hours of maceration are usually sufficient. The infusion is then to be concentrated by evaporation at a temperature not exceeding 160° to the sp. gr. 1·200, and as much alcohol is to be added as will make its sp. gr. 1·100. These preparations are very analogous to the *fluid extracts* already treated of. As a general rule, it would probably be preferable to prepare the infusion by the process of percolation. The inspissated infusions must be diluted when administered. The presence of alcohol, though in small quantity, would in some instances be a serious objection. (*Pharm. Journ.*, x. 129.)

As we have already treated of the chemical relations and medical properties of the substances used in infusion, it would be useless repetition to enlarge upon these points in the following details. We shall touch upon them only in cases of peculiar interest, or where changes requiring particular notice may grow out of the nature of the process.

The former officinal preparations of this class, omitted in the present U. S.

of course always be above the medicinal substance placed upon the diaphragm. (See *Am. Journ. of Pharm.*, viii. 89.)

Squire's Infusion Jar. Mr. Squire, of London, has modified this jar by adding a colander of queensware, which is closely covered with a lid, and descends into the jar so as to form a diaphragm for the support of the substance to be infused. It has the advantage that the material, after having been exhausted, may be lifted out without disturbing the infusion. In the margin is a figure of Squire's implement. It consists of a queensware mug, of the capacity of two pints, into which a thimble-shaped colander descends to somewhat less than half its depth, supported on the rim of the mug by a projecting ledge, with a carefully fitted cover, which closes the whole. The substance to be submitted to infusion is introduced into the colander either before or after it has been fitted to the mug; the water, hot or cold, as the case may be, is then poured in so as to fill the lower vessel, and cover the materials in the upper; and, the cover having been applied, the vessel is set aside for the length of time required. The colander is then to be lifted out, and the infusion is ready for use. For preparing small quantities of infusion, a pint for example, the mug must be made of a smaller size.

and Br. Pharmacopœias, are the *Infusions of Horseradish*, U. S., Lond., of *Pale Peruvian Bark*, Lond., Dub., Ed., and of *Simaruba*, Ed., Dub.; the *Inspissated Infusions of Yellow and Pale Bark*, Lond.; and the *Compound Infusion of Senna*, Ed. The U. S. *Infusions of Sassafras Pith* and of *Slippery-elm Bark* have been transferred to the *Mucilages*. W.

INFUSUM ANGUSTURÆ. *U. S.* INFUSUM CUSPARIÆ. *Br. Infusion of Angustura. Infusion of Cusparia.*

"Take of Angustura [Bark], in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity*. Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This Infusion may also be prepared by macerating the Angustura in a pint of Boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Cusparia Bark, in coarse powder, *half an ounce* [avoirdupois]; Distilled Water, at 120°, *ten fluidounces*. Infuse in a covered vessel, for two hours, and strain." *Br.*

The dose of the infusion is two fluidounces, repeated every two, three, or four hours. W.

INFUSUM ANTHEMIDIS. *U. S., Br. Infusion of Chamomile.*

"Take of Chamomile *half a troyounce;* Boiling Water *a pint*. Macerate for ten minutes in a covered vessel, and strain." *U. S.*

"Take of Chamomile Flowers *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces*. Infuse in a covered vessel, for fifteen minutes, and strain." *Br.*

The infusion of chamomile has the odour and taste of the flowers. It affords precipitates with gelatin, yellow Peruvian bark, sulphate of iron, tincture of chloride of iron, nitrate of silver, corrosive chloride of mercury, and the acetates of lead. (*London Dispensatory.*) As a tonic it is given cold, in the dose of two fluidounces several times a day. To assist the operation of emetic medicines it should be administered in the tepid state, and in large draughts. The infusion prepared by maceration in cold water is more grateful to the palate and stomach than that made with boiling water, but is less efficient as an emetic. W.

INFUSUM AURANTII. *Br. Infusion of Orange Peel.*

"Take of Bitter Orange Peel, cut small, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces*. Infuse in a covered vessel, for fifteen minutes, and strain." *Br.*

This infusion is given as a grateful stomachic, in the dose of two or three fluidounces. W.

INFUSUM AURANTII COMPOSITUM. *Br. Compound Infusion of Orange Peel.*

"Take of Bitter Orange Peel, cut small, *one-quarter of an ounce* [avoirdupois]; Fresh Lemon Peel, cut small, *sixty grains;* Cloves, bruised, *thirty grains;* Boiling Distilled Water *ten fluidounces* [Imperial measure]. Infuse in a covered vessel for a quarter of an hour, and strain."

A grateful stomachic in the dose of one or two fluidounces. W.

INFUSUM BUCHU. *U. S., Br. Infusion of Buchu.*

"Take of Buchu *a troyounce;* Boiling Water *a pint*. Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Buchu Leaves, bruised, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces*. Infuse in a covered vessel, for one hour, and strain." *Br.*

This is the *Infusum Diosmæ* of former Pharmacopœias. It has the odour, taste, and medical virtues of the leaves, and affords a convenient method of administering the medicine. The dose is one or two fluidounces. W.

INFUSUM CALUMBÆ. *U. S., Br.* INFUSUM COLOMBÆ. *U. S.* 1850. *Infusion of Columbo. Infusion of Calumba.*

"Take of Columbo, in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity.* Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This infusion may also be prepared by macerating the Columbo in a pint of boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Calumba Root, cut small, *half an ounce* [avoirdupois]; Cold Distilled Water *ten fluidounces.* Macerate in a covered vessel, for one hour, and strain." *Br.*

The infusion of Columbo is apt to spoil very quickly, especially in warm weather. It has been generally supposed that the cold infusion would keep better than the hot, because it contains no starch. Mr. Thomas Greenish, however, upon comparing specimens of the two infusions, found that the spontaneous change began sooner in the cold than the hot, though the former was clearer. Columbo contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change; but the former is much the more permanent of the two. Hence it is, according to Mr. Greenish, that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a little albumen, which has escaped coagulation. According to these views, the best plan of preparing infusion of columbo is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (*Am. Journ. of Pharm.*, xviii. 141; from *Pharm. Journ.*) Upon comparing specimens of the cold and hot infusion, we have not found the results of Mr. Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless, the plan of preparing the infusion above proposed is probably the best. The infusion of columbo is not disturbed by salts of iron, and may be conveniently administered in connection with them. The dose is two fluidounces three or four times a day. W.

INFUSUM CAPSICI. *U. S. Infusion of Capsicum.*

"Take of Capsicum, in coarse powder, *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This infusion is used chiefly as a gargle. It may, however, be given internally in the dose of half a fluidounce. W.

INFUSUM CARYOPHYLLI. *U. S., Br. Infusion of Cloves.*

"Take of Cloves, bruised, *one hundred and twenty grains;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Cloves, bruised, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The infusion of cloves affords precipitates with lime-water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (*Phillips.*) The dose is about two fluidounces. W.

INFUSUM CASCARILLÆ. *U. S., Br. Infusion of Cascarilla.*

"Take of Cascarilla, in moderately coarse powder, *a troyounce;* Water *a sufficient quantity.* Moisten the powder with half a fluidounce of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This infusion may also be prepared by macerating the Cascarilla with a pint of boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Cascarilla Bark, in coarse powder, *one ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

This infusion affords precipitates with lime-water, infusion of galls, nitrate of silver, acetate and subacetate of lead, sulphate of zinc, and sulphate of iron. (*London Dispensatory.*) The medium dose is two fluidounces. W.

INFUSUM CATECHU COMPOSITUM. *U.S.* INFUSUM CATECHU. *Br. Compound Infusion of Catechu. Infusion of Catechu.*

"Take of Catechu, in fine powder, *half a troyounce;* Cinnamon, in moderately fine powder, *sixty grains;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

"Take of Catechu, in coarse powder, *one hundred and sixty grains:* Cinnamon Bark, bruised, *thirty grains;* Boiling Distilled Water *ten fluidounces* [Imperial measure]. Infuse in a covered vessel, for half an hour, and strain." *Br.*

This is an elegant mode of administering catechu. The dose is from one to three fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM CHIRATÆ. *Br. Infusion of Chiretta.*

"Take of Chiretta, cut small, *a quarter of an ounce* [avoirdupois]; Distilled Water, at 120°, *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The dose of this simple bitter is from one to three fluidounces. W.

INFUSUM CINCHONÆ FLAVÆ. *U.S., Br. Infusion of Yellow Cinchona. Infusion of Yellow Bark.*

"Take of Yellow Cinchona, in moderately fine powder, *a troyounce;* Aromatic Sulphuric Acid *a fluidrachm;* Water *a sufficient quantity.* Mix the Acid with a pint of Water. Then moisten the powder with half a fluidounce of the mixture, and, having packed it firmly in a conical glass percolator, gradually pour upon it the remainder of the mixture, and afterwards Water, until the filtered liquid measures a pint." *U. S.*

"Take of Yellow Cinchona Bark, in coarse powder, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for two hours, and strain." *Br.*

Though the infusion with boiling water is more quickly prepared than the cold infusion, and therefore better adapted to cases of emergency, yet the latter is a more elegant preparation, not turbid like the former, and at least equally efficient. We, therefore, prefer the process of the U. S. Pharmacopœia, provided it be skilfully conducted.

The U. S. infusion is an elegant and very efficient preparation. Water extracts from bark the kinates of quinia and cinchonia, but leaves behind the compounds which these principles form with the cinchotannic acid. The simple infusion, therefore, is rather feeble. But the addition of the acid ensures the solution of all or nearly all the active matter. We have been long in the habit of using this infusion, and have had reason to be satisfied with its efficacy. It would be best that the bark should be macerated with the acidulated water some time before being introduced into the instrument.

The infusion of cinchona, made without acid, affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive chloride of mercury, arsenious acid, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, columbo, cascarilla, horseradish, cloves, catechu, orange-peel, foxglove, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. (*London Dispensatory.*) Few, however, of these substances diminish the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. As gallic, tartaric, and oxalic acids form salts with quinia of somewhat difficult solubility, the neutral and soluble gallates, tartrates, and oxalates produce in the infusion slight precipitates of corresponding salts of the alkaloids; but these are redissolved by an excess of the acid. Tartrate of antimony and potassa does not precipitate the alkaloids.

Solutions of iodine are incompatible by forming with the alkaloids insoluble compounds. For an account of the chemical reactions of the infusions of different varieties of Peruvian bark, see the *Am. Journ. of Pharm.* (ix. 128).

The simple infusion of cinchona may be advantageously administered in cases which require tonic treatment, but do not call for the full powers of the bark. The acid infusion has, we believe, all the powers of cinchona itself, and may be given for the same purposes. The medium dose is two fluidounces, equivalent to a drachm of the bark, to be repeated three or four times a day as a tonic, but more frequently as an antiperiodic. W.

INFUSUM CINCHONÆ RUBRÆ. *U. S.* INFUSUM CINCHONÆ COMPOSITUM. *U. S.* 1850. *Infusion of Red Cinchona. Compound Infusion of Peruvian Bark. Infusion of Red Bark.*

"Take of Red Cinchona, in moderately fine powder, *a troyounce;* Aromatic Sulphuric Acid *a fluidrachm;* Water *a sufficient quantity.* Mix the Acid with a pint of Water. Then moisten the powder with half a fluidounce of the mixture, and, having packed it firmly in a conical glass percolator, gradually pour upon it the remainder of the mixture, and afterwards Water, until the filtered liquid measures a pint." *U. S.*

The remarks made in relation to infusion of yellow bark are equally applicable to this. W.

INFUSUM CUSSO. *Br. Infusion of Kousso.*

"Take of Kousso, in coarse powder, *one half of an ounce* [avoirdupois]; Boiling Distilled Water *eight fluidounces.* Infuse in a covered vessel, for fifteen minutes, without straining." *Br.*

The whole may be taken for a dose. W.

INFUSUM DIGITALIS. *U. S., Br. Infusion of Digitalis.*

"Take of Digitalis [dried leaves], in coarse powder, *sixty grains;* Tincture of Cinnamon *a fluidounce;* Boiling Water *half a pint.* Macerate the Digitalis with the Water for two hours in a covered vessel, and strain; then add the Tincture of Cinnamon, and mix." *U. S.*

"Take of Digitalis Leaves, dried, *thirty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The U. S. infusion is essentially the same as that employed by Withering. It affords precipitates with sulphate of iron, acetate of lead, tannic acid, and infusion of Peruvian bark. The dose has usually been stated at half a fluidounce, repeated twice a day under ordinary circumstances, every eight hours in urgent cases, until the system is affected. The proportion of digitalis is scarcely half as great in the British preparation, and the dose is proportionably larger. It will not escape the close observer, that the stated dose of digitalis in infusion is much larger than in substance, for which there does not appear to be a good reason. It would be safer to give only half the quantity, and increase if necessary. The British Pharmacopœia, though its infusion has only about half the strength of ours, gives its dose as from two to four fluidrachms. W.

INFUSUM DULCAMARÆ. *Br. Infusion of Dulcamara.*

"Take of Dulcamara, bruised, *one ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The dose is one or two fluidounces three or four times a day. W.

INFUSUM ERGOTÆ. *Br. Infusion of Ergot.*

"Take of Ergot, in coarse powder, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The dose of this infusion is two fluidounces for a woman in labour. W

INFUSUM EUPATORII. *U. S. Infusion of Thoroughwort.*

"Take of Thoroughwort [the dried herb] *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

As a tonic, this infusion should be taken cold in the dose of one or two fluidounces three or four times a day, or more frequently; as an emetic and diaphoretic, in large tepid draughts. W.

INFUSUM GENTIANÆ COMPOSITUM. *U.S.*, *Br.* *Compound Infusion of Gentian.*

"Take of Gentian, in moderately coarse powder, *half a troyounce;* Bitter Orange Peel, in moderately coarse powder, Coriander, in moderately coarse powder, each, *sixty grains;* Alcohol *two fluidounces;* Water *a sufficient quantity.* Mix the Alcohol with fourteen fluidounces of Water, and, having moistened the mixed powders with three fluidrachms of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them first the remainder of the menstruum, and afterwards Water, until the filtered liquid measures a pint." *U. S.*

"Take of Gentian Root, sliced, Bitter-Orange Peel, cut small, of each, *sixty grains;* Fresh Lemon Peel, cut small, *one-quarter of an ounce;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The use of the alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very apt to spoil. It has, however, been abandoned by the British Pharmacopœia, and lemon peel substituted; a very doubtful improvement. The dose is a fluidounce repeated three or four times a day. W.

INFUSUM HUMULI. *U.S.* INFUSUM LUPULI. *Br.* *Infusion of Hops.*

"Take of Hops *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Hop *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for two hours, and strain." *Br.*

The dose of this infusion is one or two fluidounces. W.

INFUSUM JUNIPERI. *U.S.* *Infusion of Juniper.*

"Take of Juniper, bruised, *a troyounce;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

The whole quantity made may be taken in twenty-four hours, in doses of two or three fluidounces. W.

INFUSUM KRAMERIÆ. *U.S.*, *Br.* *Infusion of Rhatany.*

"Take of Rhatany, in moderately coarse powder, *a troyounce;* Water *a sufficient quantity.* Moisten the powder with half a fluidounce of Water, and, having packed it firmly in a conical glass percolator, gradually pour Water upon it until the filtered liquid measures a pint." *U. S.*

"Take of Rhatany Root, bruised, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The infusion of rhatany is probably most efficient, prepared by the mode of percolation, with cold water, from the root in a state of moderately coarse powder, as directed in the U. S. process. The dose of the infusion is one or two fluidounces. W.

INFUSUM LINI COMPOSITUM. *U.S.* INFUSUM LINI. *Br.* *Compound Infusion of Flaxseed. Infusion of Linseed.*

"Take of Flaxseed *half a troyounce;* Liquorice Root, bruised, *one hundred and twenty grains;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Linseed *one hundred and sixty grains;* Fresh Liquorice Root, sliced, *sixty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for four hours, and strain" *Br.*

This is a useful demulcent drink in inflammatory affections of the mucous membrane of the lungs and urinary passages. It may be taken *ad libitum.* W.

INFUSUM MATICÆ. *Br.* *Infusion of Matico.*

"Take of Matico Leaves, cut small, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The dose of this infusion is two fluidounces. W.

INFUSUM PAREIRÆ. *U.S.* *Infusion of Pareira Brava.*

"Take of Pareira Brava, bruised, *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The infusion of pareira brava is highly esteemed by some English practitioners as a remedy in irritation and chronic inflammation of the urinary passages, and has been found useful in catarrh of the bladder. The dose is one or two fluidounces. Brodie employed a *decoction* of the root, which he prepared by boiling half an ounce in three pints of water down to a pint, and gave in the quantity of from eight to twelve fluidounces daily. The Br. Pharmacopœia has substituted the decoction for the infusion. W.

INFUSUM PICIS LIQUIDÆ. *U.S.* *Infusion of Tar. Tar Water.*

"Take of Tar *a pint;* Water *four pints.* Mix them, and shake the mixture frequently during twenty-four hours. Then pour off the infusion, and filter through paper." *U. S.*

Water takes from tar a small portion of acetic acid, empyreumatic oil including creasote, and resinous matter, acquiring a sharp empyreumatic taste, the odour of tar, and the colour of Madeira wine. Thus impregnated it is stimulant and diuretic, and may be taken in the quantity of one or two pints daily. It is also used as a wash in chronic cutaneous affections, and is said to have proved beneficial, by injection into the bladder, in some cases of chronic cystitis. W.

INFUSUM PRUNI VIRGINIANÆ. *U. S.* *Infusion of Wild-cherry Bark.*

"Take of Wild-cherry Bark, in moderately coarse powder, *half a troyounce;* Water [cold] *a sufficient quantity.* Moisten the powder with six fluidrachms of Water, let it stand for an hour, pack it gently in a conical glass percolator, and gradually pour Water upon it until the filtered liquid measures a pint." *U. S.*

This is a peculiarly suitable object for officinal direction, as, in consequence of the volatile nature of one of its active ingredients, and for another reason before stated (see *pages* 718–9), it is better prepared with cold water than in the ordinary mode. The infusion of wild-cherry bark is one of the preparations to which the process of percolation or displacement is well adapted. In this way the virtues of the bark can be more rapidly and thoroughly exhausted than by maceration alone. In order to allow time for the reaction necessary to the production of the hydrocyanic acid, an hour's preliminary maceration is directed, which might perhaps be advantageously somewhat lengthened. When properly made, the infusion is beautifully transparent, has the colour of Madeira wine, and the agreeable bitterness and peculiar flavour of the bark. The dose is two or three fluidounces three or four times a day, or more frequently when a strong impression is required. W.

INFUSUM QUASSIÆ. *U.S., Br.* *Infusion of Quassia.*

"Take of Quassia, rasped, *one hundred and twenty grains;* Water [cold] *a pint.* Macerate for twelve hours, in a covered vessel, and strain." *U. S.*

"Take of Quassia Wood, in chips, *sixty grains;* Cold Distilled Water *ten fluidounces.* Macerate in a covered vessel, for half an hour, and strain." *Br.*

The proportion of Quassia directed in the former London and Edinburgh Pharmacopœias was much too small. The London infusion contained the strength of only two grains of quassia in a fluidounce, and the Edinburgh three grains; while the dose of quassia in substance is from twenty grains to a drachm, and of the extract not less than five grains. This error has been corrected in the British Pharmacopœia. Boiling water may be employed when it is desirable to obtain the preparation quickly; but cold water affords a clearer

infusion. The half-hour maceration directed in the British Pharmacopœia, considering that cold water is used, appears to us to be too short for the exhaustion of the wood. The dose is two fluidounces three or four times a day. W.

INFUSUM RHEI. *U.S., Br. Infusion of Rhubarb.*

"Take of Rhubarb, bruised, *one hundred and twenty grains;* Boiling Water *half a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Rhubarb Root, in thin slices, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

In order that the rhubarb may be exhausted, it should be digested with the water near the fire, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel-seed, or nutmeg, which improves the taste of the infusion, and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connection with the rhubarb.

This infusion may be given as a gentle laxative, in the dose of one or two fluidounces, every three or four hours till it operates. It is occasionally used as a vehicle of tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it. W.

INFUSUM ROSÆ COMPOSITUM. *U.S.* INFUSUM ROSÆ ACIDUM. *Br. Compound Infusion of Rose. Acid Infusion of Roses.*

"Take of Red Rose [dried petals] *half a troyounce;* Diluted Sulphuric Acid *three fluidrachms;* Sugar [refined], in coarse powder, *a troyounce and a half;* Boiling Water *two pints and a half.* Pour the Water upon the Rose in a covered glass or porcelain vessel; then add the Acid, and macerate for half an hour. Lastly, strain the liquid, and in it dissolve the Sugar." *U. S.*

"Take of Dried Red-rose Petals, broken up, *a quarter of an ounce* [avoirdupois]; Diluted Sulphuric Acid *one fluidrachm;* Boiling Distilled Water *ten fluidounces.* Add the Acid to the Water, infuse the Petals in the mixture in a covered vessel, for half an hour, and strain." *Br.*

The red roses serve little other purpose than to impart a fine red colour and a slight astringent flavour to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. It is refrigerant and astringent, and affords a useful and not unpleasant drink in hemorrhages and colliquative sweats. It is much used by British practitioners as a vehicle for saline medicines, particularly sulphate of magnesia, the taste of which it serves to cover. It is also employed as a gargle, usually in connection with acids, nitre, alum, or tincture of Cayenne pepper. The dose is from two to four fluidounces. W.

INFUSUM SALVIÆ. *U.S. Infusion of Sage.*

"Take of Sage *half a troyounce;* Boiling Water *a pint.* Macerate for half an hour in a covered vessel, and strain." *U. S.*

This preparation is less used internally than as a gargle, or as a vehicle for other substances, such as alum, employed in this way. W.

INFUSUM SENEGÆ. *Br. Infusion of Seneka.*

"Take of Senega Root, bruised, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The efficacy of the officinal decoction of seneka has been proved by so long an experience, that we should be cautious in allowing it to be superseded by the infusion on hypothetical grounds. The dose of the preparation is from one to three fluidounces. W.

INFUSUM SENNÆ. *U.S., Br. Infusion of Senna.*

"Take of Senna *a troyounce;* Coriander, bruised, *sixty grains;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

"Take of Senna *one ounce* [avoirdupois]; Ginger, sliced, *thirty grains;*

Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

We prefer the coriander of the U. S. Pharmacopœia to the ginger of the British. The strength of the British preparation has been doubled in the present edition of the Pharmacopœia, and is now nearly twice as great as that of the U. S. infusion. The infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to connect with it manna and some one of the saline cathartics, which increase its efficacy, and render it less painful in its operation. The following is a good formula for the preparation of senna tea. Take of senna *half an ounce;* sulphate of magnesia, manna, each, *an ounce;* fennel-seed *a drachm;* boiling water *half a pint.* Macerate in a covered vessel till the liquid cools. One-third may be given for a dose, and repeated every four or five hours till it operates. Such a combination as this is called *the black draught* by English writers. The dose of the infusion of the U. S. Pharmacopœia is about four fluidounces.

The cold infusion, especially if made by percolation from the coarsely powdered leaves, while probably not inferior in strength to that prepared with boiling water, is said to be less unpleasant to the taste. W.

INFUSUM SERPENTARIÆ. *U. S., Br. Infusion of Serpentaria.*

"Take of Serpentaria, in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity.* Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This infusion may also be prepared by macerating the Serpentaria with a pint of boiling water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Serpentary Root, bruised, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel for two hours, and strain." *Br.*

This is the ordinary form in which serpentaria is employed. The dose is one or two fluidounces, repeated every two hours in low forms of fever, but less frequently in chronic affections. W.

INFUSUM SPIGELIÆ. *U. S. Infusion of Spigelia.*

"Take of Spigelia *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The dose of this infusion, for a child two or three years old, is from four fluidrachms to a fluidounce; for an adult, from four to eight fluidounces, repeated morning and evening. A quantity of senna equal to that of the spigelia is usually added, in order to ensure a cathartic effect. W.

INFUSUM TABACI. *U. S.* Enema Tabaci. *Br. Infusion of Tobacco.*

"Take of Tobacco *sixty grains;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

For the mode of preparing the British *Enema Tabaci,* see *page* 1117.

This is used only in the form of enema in strangulated hernia, obstinate colic, and retention of urine from spasm of the urethra. Only half of the pint of the U. S. infusion should be employed at once; and, if this should not produce relaxation in half an hour, the remainder may be injected. Fatal consequences have resulted from too free a use of tobacco in this way. W.

INFUSUM TARAXACI. *U. S. Infusion of Dandelion.*

"Take of Dandelion, bruised, *two troyounces;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This has been substituted in the U. S. Pharmacopœia for the decoction. The dose is a wineglassful two or three times a day, or oftener. W.

INFUSUM UVÆ URSI. *Br. Infusion of Bearberry.*

"Take of Bearberry Leaves, bruised, *half an ounce* [avoirdupois]; Boiling

Distilled Water *ten fluidounces.* Infuse in a covered vessel, for two hours, and strain through calico." *Br.*

The dose is one or two fluidounces three or four times a day. W.

INFUSUM VALERIANÆ. *U. S., Br. Infusion of Valerian.*

"Take of Valerian, in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity.* Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This Infusion may also be prepared by macerating the Valerian with a pint of Boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Valerian Root, bruised, *one hundred and twenty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel for one hour, and strain." *Br.*

The dose of this infusion is two fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM ZINGIBERIS. *U. S. Infusion of Ginger.*

"Take of Ginger, bruised, *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The dose of this infusion is two fluidounces W

LINIMENTA.

Liniments.

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand. They are usually thicker than water, but thinner than the ointments, and are always liquid at the temperature of the body. The former officinal preparations, belonging to this class, which have been omitted in the present editions of the U. S. and Br. Pharmacopœias, are the *Liniments of Verdigris*, Lond., and of *Sesquicarbonate of Ammonia*, Lond.; the *Compound Liniment of Ammonia*, Ed.; the *Camphorated Soap Liniment*, or *Opodeldoc*, U. S.; and the *Simple Liniment*, Ed.

LINIMENTUM ACONITI. *Br. Liniment of Aconite.*

"Take of Aconite Root, in coarse powder, *twenty ounces* [avoirdupois]; Camphor *one ounce* [avoird.]; Rectified Spirit *a sufficiency.* Moisten the Aconite Root with some of the Spirit, and macerate in a close vessel for three days; then transfer to a percolator, and adding more Spirit percolate slowly into a receiver containing the Camphor, until the product measures one pint [Imperial measure]." *Br.*

This is a very strong tincture of aconite root, intended only for external use.* (See *Aconiti Radicis.*) It may be applied alone by means of a camel's-hair pencil, or in connection with two parts or more of soap liniment or chloroform liniment, by rubbing it on the part affected. Experiments made by Mr. W. Donovan with a tincture prepared by macerating the fresh root, sliced, in rectified spirit for only twenty-four hours, proved that the preparation thus made, though

* *A liniment of aconite* has for some years been considerably employed in Philadelphia, prepared according to the following formula of Prof. Procter. Take of Aconite Root, in powder, *four troyounces*, Glycerin *two fluidrachms*, Alcohol *a sufficient quantity.* Macerate the Aconite with half a pint of Alcohol for *twenty-four hours;* then pack it in a small percolator, and gradually pour Alcohol upon it until a pint of tincture has passed. Distil off twelve fluidounces, and evaporate the residue until it measures twelve fluidrachms, to which the glycerin and two fluidrachms of alcohol are to be added, making the resulting fluid extract measure two fluidounces. Each minim of this represents two grains of the root, and, if the aconite is exhausted in the process, and nothing lost during the evaporation, both of which conditions we understand to be fulfilled in the process, the preparation is twice as strong as the British liniment. It is intended, as its name implies, only for external use. It may be used in the same manner as the liniment described in the text. (*Am. Journ. of Pharm.*, xxv. 293.)—*Note to the twelfth edition.*

acting in the same way, was much more powerful than the officinal. (*Pharm. Journ.*, 2d ser., vi. 57.) The inference is that the fresh root should be used in preparing this liniment, and that a simple maceration is all that is required. There is a great waste both of aconite and of spirit in the process; as no provision is made, either by displacement with water, or by expression, to separate from the mass in the percolator the strongly impregnated spirit retained in it. W.

LINIMENTUM AMMONIÆ. *U. S., Br. Liniment of Ammonia. Volatile Liniment.*

"Take of Water of Ammonia *a fluidounce;* Olive Oil *two troyounces.* Mix them." *U. S.*

"Take of Solution of Ammonia *one fluidounce;* Olive Oil *three fluidounces.* Mix together with agitation." *Br.*

The U. S. and British Pharmacopœias agree at present very nearly in the strength of this liniment; the U. S. preparation being somewhat the stronger. In the process, the ammonia reacts with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, frequently employed in inflammatory affections of the throat, catarrhal and other pectoral complaints of children, and in rheumatic pains. It is applied by rubbing it gently upon the skin, or placing a piece of flannel saturated with it over the affected part. Should it occasion too much inflammation, it must be diluted with oil. W.

LINIMENTUM BELLADONNÆ. *Br. Liniment of Belladonna.*

This is prepared from Belladonna Root precisely as the Liniment of Aconite is prepared from Aconite Root; and the same remarks are applicable as to its strength and use; especially in relation to the waste incurred in the process. (See *Linimentum Aconiti.*)

LINIMENTUM CALCIS. *U. S., Br. Lime Liniment.*

"Take of Solution of Lime *eight fluidounces;* Flaxseed Oil *seven troyounces.* Mix them." *U. S.*

"Take of Solution of Lime, Olive Oil, of each, *two fluidounces.* Mix together with agitation." *Br.*

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the British Pharmacopœia, is often substituted for that of flaxseed, but possesses no other advantage than that of having a less unpleasant odour. This is a very useful liniment in recent burns and scalds. It is sometimes called *Carron oil*, from having been much employed at the Carron iron works in Scotland. It is recommended to be applied upon some carded cotton. W.

LINIMENTUM CAMPHORÆ. *U. S., Br. Liniment of Camphor.*

"Take of Camphor *three troyounces;* Olive Oil *twelve troyounces.* Dissolve the Camphor in the Oil." *U. S.*

"Take of Camphor *one ounce* [avoirdupois]; Olive Oil *four fluidounces.* Dissolve the Camphor in the Oil." *Br.*

This is employed as an anodyne embrocation in sprains, bruises, rheumatic or gouty affections of the joints, and other local pains. It is also supposed to have a discutient effect when rubbed upon glandular swellings.

Mr. Wm. B. Price, of Burlington, N. J., proposes a modification of this liniment, founded on the solvent power of chloroform over camphor, whereby the preparation is made stronger with camphor, and acquires also additional anodyne influence from the chloroform. The proposed liniment consists of *an ounce and a half* of camphor, *two fluidrachms* of chloroform, and *two fluidounces* of olive oil. It is useful in rheumatic and neuralgic pains. (*N. J. Med. Reporter*, ii. 217.)

Off. Prep. Linimentum Chloroformi, *Br.;* Linimentum Hydrargyri, *Br.;* Linimentum Terebinthinæ Aceticum, *Br.* W.

LINIMENTUM CAMPHORÆ COMPOSITUM. *Br. Compound Liniment of Camphor.*

"Take of Camphor *two ounces and a half* [avoirdupois]; Oil of Lavender *one fluidrachm;* Strong Solution of Ammonia *five fluidounces;* Rectified Spirit *fifteen fluidounces.* Dissolve the Camphor and Oil of Lavender in the Spirit; then add the Solution of Ammonia gradually, shaking them together until a clear solution is formed." *Br.*

This is used as a rubefacient and at the same time anodyne embrocation in local pains, particularly of a rheumatic character. W.

LINIMENTUM CANTHARIDIS. *U. S., Br.* 1864. LIQUOR EPISPASTICUS. *Br. Liniment of Cantharides. Blistering Liquid.*

"Take of Cantharides, in fine powder, *a troyounce;* Oil of Turpentine *half a pint.* Digest the Cantharides with the Oil for three hours in a close vessel, by means of a water-bath, and strain." *U. S.*

"Take of Cantharides, in powder, *eight ounces* [avoirdupois]; Acetic Acid *four fluidounces;* Ether *a sufficiency.* Mix the Cantharides and Acetic Acid; pack them in a percolator, and at the expiration of twenty-four hours pour ether over the contents of the percolator, and allow it to pass slowly through till twenty fluidounces are obtained. Keep it in a stoppered bottle." *Br.*

Oil of turpentine dissolves, especially with the aid of heat, the active principle of cantharides, and, when impregnated with it, acquires in addition to its own rubefacient properties those of a powerful epispastic. The U. S. liniment was introduced into notice by the late Dr. Joseph Hartshorne, of Philadelphia, who employed it with advantage as an external stimulant in the prostrate states of typhus fever. Caution, however, is necessary in its use, both to graduate its strength to the circumstances of the case, and not to apply it very extensively, lest it may produce troublesome, if not dangerous vesication. If too powerful, it may be diluted with olive or linseed oil. The British preparation is a solution of the active matter of the flies in acetic acid and ether, and, as the ether must quickly evaporate, conjoins the influence of the cantharides and the acid. From the name conferred upon it at the late revision of the Pharmacopœia, it would appear to be intended rather as a vesicating than a rubefacient agent. W.

LINIMENTUM CHLOROFORMI. *U. S., Br. Liniment of Chloroform.*

"Take of Purified Chloroform *three troyounces;* Olive Oil *four troyounces.* Mix them." *U. S.*

"Take of Chloroform, Liniment of Camphor, of each, *two fluidounces.* Mix." *Br.*

This is an excellent local application in painful affections, though the common commercial chloroform would have answered quite as well as the purified, directed in the U. S. formula. As the chloroform rapidly evaporates, it is desirable, in order to obtain its full anodyne effect, to guard against this by oiled silk or some other impermeable covering. As some object to the greasy residue left on the skin by the evaporation of the chloroform, the soap liniment, which can readily be removed with a little warm water, may be substituted for the olive oil of the U. S., or the camphor liniment of the British preparation. W.

LINIMENTUM CROTONIS. *Br. Liniment of Croton Oil.*

"Take of Croton Oil *one fluidounce;* Oil of Cajuput, Rectified Spirit, of each, *three fluidounces and a half.* Mix." *Br.*

This is a pustulating preparation, the irritant influence of which has been increased by the substitution of the oil of cajuput and the spirit for the olive oil of the original formula, which tended to weaken the croton oil. From ten to thirty minims or more may be rubbed upon a limited surface, and repeated twice a day or oftener till an eruption is produced. W.

LINIMENTUM HYDRARGYRI. *Br. Liniment of Mercury.*

"Take of Ointment of Mercury *one ounce* [avoirdupois]; Solution of Am-

monia, Liniment of Camphor, of each, *one fluidounce.* Liquefy the Ointment of Mercury in the Liniment of Camphor with a gentle heat, then add the Solution of Ammonia gradually and mix with agitation." *Br.*

This is a stimulating liniment, employed for the discussion of chronic glandular enlargements, swellings of the joints, and venereal tumours, and to promote the absorption of collections of fluid. It is said to be more apt to salivate than mercurial ointment. One drachm of it may be rubbed upon the affected part night and morning. W.

LINIMENTUM IODI. *Br. Liniment of Iodine.*

"Take of Iodine *one ounce and a quarter* [avoirdupois]; Iodide of Potassium *half an ounce* [avoird.]; Camphor *one-fourth of an ounce;* Rectified Spirit *ten fluidounces.* Dissolve the Iodine, Iodide of Potassium, and Camphor in the Spirit." *Br.*

This is an alcoholic solution of iodine, in which the iodide of potassium acts by increasing the solubility of the active ingredient. The strength of the solution has been reduced one-half in the present liniment. See for its effects the article on Iodine in the first part of this work. W.

LINIMENTUM OPII. *Br. Liniment of Opium. Anodyne Liniment.*

"Take of Tincture of Opium, Liniment of Soap, of each, *two fluidounces.* Mix." *Br.*

This is commonly called *anodyne liniment,* and is employed as an anodyne and gently rubefacient embrocation in sprains, bruises, and rheumatic and gouty pains. We are informed that the preparation which has commonly been used, under the name of *anodyne liniment,* in this city, is that of the late London Pharmacopœia, as given in former editions of the U. S. Dispensatory, consisting of one part by measure of tincture of opium and three of soap liniment, and consequently having only half the opiate strength of the present British liniment. W.

LINIMENTUM POTASSII IODIDI CUM SAPONE. *Br. Liniment of Iodide of Potassium and Soap.*

"Take of Hard Soap, cut small, Iodide of Potassium, of each, *one ounce and a half* [avoirdupois]; Glycerine *one fluidounce;* Oil of Lemon *one fluidrachm;* Distilled Water *ten fluidounces.* Dissolve the Soap in seven fluidounces of the Water by the heat of a water-bath. Dissolve the Iodide of Potassium and Glycerine in the remainder of the Water, and mix the two solutions together. When the mixture is cold add the Oil of Lemon and mix the whole thoroughly." *Br.*

This preparation is apparently intended, by application to the surface, which may be attended with a gentle friction, to produce the absorption of the iodide, and thus to obtain its alterative and deobstruent effects through the circulation. The soap and glycerin act as demulcents, and thus obviate in some measure the local irritation of the salt. W.

LINIMENTUM SAPONIS. *U. S., Br.* TINCTURA SAPONIS CAMPHORATA. *U. S.* 1850. *Soap Liniment. Camphorated Tincture of Soap.*

"Take of Soap, in shavings, *four troyounces;* Camphor *two troyounces;* Oil of Rosemary *half a fluidounce;* Water *four fluidounces;* Alcohol *two pints.* Mix the Alcohol and Water, digest the Soap with the mixture, by means of a water-bath, until it is dissolved; then filter, and, having added the Camphor and Oil, mix the whole thoroughly together." *U. S.*

"Take of Hard Soap, cut small, *two ounces and a half* [avoirdupois]; Camphor *one ounce and a quarter* [avoird.]; Oil of Rosemary *three fluidrachms;* Rectified Spirit *eighteen fluidounces;* Distilled Water *two fluidounces.* Mix the Water with the Spirit, and add the Oil of Rosemary, the Soap, and the Camphor. Macerate for seven days at a temperature not exceeding 70°, with occasional agitation, and filter." *Br.*

It is necessary, in preparing this liniment, that the soap employed should not

have been made with animal oil, as otherwise the preparation will not be fluid at ordinary temperatures. The soap indicated by the U. S. Pharmacopœia is that "prepared from soda and olive oil," commonly called *Castile soap.* Made according to the directions of the U. S. Pharmacopœia of 1840, the tincture was unable to retain the soap in solution, and therefore coagulated more or less on cooling. This defect was corrected in the edition of 1850, by the addition of water; and a similar reformation has been made in the British process.*

In former editions of the U. S. Pharmacopœia, this preparation, though commonly called *Soap liniment*, received the name of *Tinctura Saponis Camphorata*, to distinguish it from a similar preparation called *Opodeldoc*, which, having a soft semi-solid consistence, was introduced with the title of *Linimentum Saponis Camphoratum.* This, having been discarded at the late revision, the Tincture reverted to its place among the liniments, and is now called simply Linimentum Saponis. But, as the old Camphorated Soap Liniment or *Opodeldoc* is an excellent preparation, and still somewhat in use, we give here the process of the Pharmacopœia of 1850 for its preparation, with some remarks on the subject.

"Take of Common Soap, sliced, *three ounces;* Camphor *an ounce;* Oil of Rosemary, Oil of Origanum, each, *a fluidrachm;* Alcohol *a pint.* Digest the Soap with the Alcohol, by means of a sand-bath, till dissolved; then add the Camphor and Oils, and when they are dissolved, pour the liquid into broad-mouthed bottles. This liniment has, when cold, the consistence of a soft ointment."

This preparation differs from the officinal Linimentum Saponis chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made of olive oil. The former is peculiarly adapted to the purposes of this formula, in consequence of assuming, when its alcoholic solution cools, the consistence characteristic of the liniment. It is customary, after the solution of the soap has been effected, to pour the liquid into small wide-mouthed glass bottles containing about four fluidounces, in which it concretes into a soft, translucent, uniform, yellowish-white mass. This liniment melts with the heat of the body, and therefore becomes liquid when rubbed on the skin.

The Soap liniment is much used, as an anodyne and gently rubefacient embrocation, in sprains, bruises, and rheumatic or gouty pains.

Off. Prep. Linimentum Opii, *Br.* W.

LINIMENTUM SINAPIS COMPOSITUM. *Br. Compound Liniment of Mustard.*

"Take of Oil of Mustard *one fluidrachm;* Ethereal Extract of Mezereon *forty grains;* Camphor *one hundred and twenty grains;* Castor Oil *five fluidrachms;* Rectified Spirit *four fluidounces.* Dissolve the Extract of Mezereon and Camphor in the Spirit, and add the Oil of Mustard and Castor Oil." *Br.*

This is a new officinal of the British Pharmacopœia, which affords a convenient method of applying the volatile oil of mustard, and may often be appropriately used as a substitute for sinapisms. The extract of mezereon is also a very energetic irritant. The castor oil seems to be added in order somewhat to increase the consistence of the liniment, and was probably chosen

* An inconvenience to which the U. S. process is exposed is the long time required to effect the solution of the soap in the mixed oil and water, the digestion occupying several hours. Mr. J. B. Moore obviates this disadvantage by substituting the "stronger alcohol" U. S. (sp. gr. 0·817) for officinal alcohol (sp. gr. 0·835) in equivalent proportion, and somewhat changing the manipulation, though with precisely the same result, as to the medicine itself, as in the officinal process. "Take of Soap ℥iv; Camphor ℥ij; Oil of Rosemary f℥ss; Boiling Water f℥viss; Stronger Alcohol f℥xxixss. Pour the Boiling Water on the Soap; stir and beat the mixture well with a spoon for about 5 minutes, or until a soft, pultaceous mass is obtained. To this gradually add the alcohol, constantly stirring until the soap is dissolved, then filter into a bottle containing the camphor and oil." We are assured that this method of preparing the liniment is perfectly satisfactory, and that the time required is greatly lessened. From five to fifteen minutes is all that is necessary for the solution, which in the officinal process consumes several hours. (*Am. J. of Pharm.*, March, 1869, p. 121.)—*Note to the thirteenth edition.*

from among oleaginous substances in consequence of its solubility in alcohol. The camphor may have some effect in moderating the pain without diminishing the rubefacient action. The effect is increased if applied on flannel, and guarded against volatilization by covering it with oiled silk. For the circumstances calling for the use of this liniment, see the article on Sinapis (*Part I., p. 812*). W.

LINIMENTUM TEREBINTHINÆ. *U.S., Br.* *Liniment of Turpentine.*

"Take of Resin Cerate *twelve troyounces;* Oil of Turpentine *half a pint.* Add the Oil to the Cerate previously melted, and mix them." *U.S.*

"Take of Soft Soap *two ounces* [avoirdupois]; Camphor *one ounce* [avoird.]; Oil of Turpentine *sixteen fluidounces.* Dissolve the Camphor in the Oil of Turpentine, then add the Soap, rubbing them together until they are thoroughly mixed." *Br.*

The U. S. preparation is the liniment originally proposed by Dr. Kentish, and subsequently so highly lauded as a remedy in burns and scalds. It should be applied as soon after the occurrence of the accident as possible, and should be discontinued when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burnt or scalded surface with pledgets of patent lint saturated with the liniment. It should not be allowed to come in contact with the sound parts. This liniment may also be successfully applied in other cases of cutaneous inflammation requiring stimulation, as in certain conditions of erysipelas. The present British preparation, so far as regards its rubefacient operation, may be looked upon as almost undiluted oil of turpentine; the soft soap having little other effect than to give consistence to the liniment, and the camphor acting as an anodyne; and both being too small in bulk materially to dilute the oil. It is quite different from the liniment of the Pharmacopœia of 1864, which was a mixture of the oil with resin ointment, almost identical with the U. S. liniment. W.

LINIMENTUM TEREBINTHINÆ ACETICUM. *Br.* *Liniment of Turpentine and Acetic Acid.*

"Take of Oil of Turpentine, Acetic Acid, Liniment of Camphor, of each, *one fluidounce.* Mix." *Br.*

This is a powerful rubefacient liniment, combining the irritant properties of the oil of turpentine and acetic acid, though somewhat diluted by the camphor liniment. W.

LIQUORES.

Solutions.

The U. S. Pharmacopœia includes, in this class of preparations, all *aqueous* solutions in which the substance acted on is wholly soluble in water, excluding those in which the dissolved matter is gaseous or very volatile, as in the Aquæ or Waters. The *Solution of Gutta-percha* is the only one in which water is not used as the menstruum; and that seems to have been placed in the present category because no better position could be found for it.

In the British Pharmacopœia it has been deemed expedient, in almost all instances in which the substance to be dissolved is an isolated solid body, to make the solutions of uniform strength, without regard to the physiological powers of the medicine, or its ordinary dose. The solutions of this kind contain four grains of the medicine to an Imperial fluidounce of the menstruum, or half a grain in a fluidrachm. There is a convenience in this plan to the prescriber, in relation to all medicines which habitually present themselves to his mind in the solid state; but to alter the strength of a solution which has been long known, and the dose of which is familiar, in order to make it conform with others, is to endanger frequent serious errors for the sake of an idea. In such medicines, for example, as Fowler's solution, the dose is fixed in the mind of the practitioner in reference

to the solution, and not to the solid medicinal substance it may contain. On the whole, therefore, we prefer the method of the U. S. Pharmacopœia, which regulates the strength of its solutions in regard to the properties of the medicine, and not in accordance with an ideal standard.

Though several of the solutions have long been officinal, it is now for the first time that, in both Pharmacopœias, they have been dislocated from their old attachments, and arranged together as a distinct class of preparations. W.

LIQUOR AMMONIÆ ACETATIS. *U. S., Br.* SPIRITUS MINDERERI. *Solution of Acetate of Ammonia. Spirit of Mindererus.*

"Take of Diluted Acetic Acid *two pints;* Carbonate of Ammonia *a sufficient quantity.* Add the Carbonate gradually to the Acid until this is saturated, and filter. This preparation, when dispensed, should be freshly made." *U. S.*

"Take of Acetic Acid *ten fluidounces* [Imperial measure]; Carbonate of Ammonia *three ounces and a quarter* [avoirdupois], or *a sufficiency;* Distilled Water *two and a half pints* [Imp. meas.]. Reduce the Carbonate of Ammonia to powder, and add it gradually to the Acetic Acid, until a neutral solution is formed, then add the Water." *Br.*

This preparation is an aqueous solution of acetate of ammonia. The U. S. process by which it is formed constitutes a case of single elective affinity. The acetic acid combines with the ammonia of the carbonate, forming the acetate of ammonia, and disengages the carbonic acid with effervescence. Distilled vinegar was formerly used, but has been abandoned for diluted acetic acid, which is much to be preferred; because, besides furnishing a solution of the acetate of uniform strength, a result which cannot be attained by the employment of distilled vinegar, it avoids the production of a brownish solution, which uniformly follows the use of the latter, especially when it has been condensed in a metallic worm. The quantity of carbonate of ammonia, necessary to saturate a given weight of the acid of average strength, cannot be laid down with precision, on account of the variable quality of the salt. The preparation, when made with the diluted acetic acid of the U. S. Pharmacopœia, contains about 6 per cent. of acetate of ammonia. It is more convenient to add the salt to the acid than the acid to the salt; as the point of saturation is thus more easily attained. In ascertaining this point by test-paper, the alkaline reaction will begin, though a portion of free acetic acid may still remain; a little of it being insufficient to overcome the natural alkaline reaction of the salt. (See *page* 22.) A complication is caused by the presence of free carbonic acid, which may be expelled from the liquid towards the end of the saturation by warming it. Supposing the carbonic acid got rid of, the best rule, perhaps, is to cease adding the carbonate of ammonia, upon the occurrence of the least sign of alkalinity.

The present British process corresponds essentially with ours; but in that of the Br. Pharmacopœia of 1864, the strong solution of ammonia was used instead of the carbonate, and the ammonia combined directly with the acetic acid, without other reaction. The solution was much stronger than that of the U. S. Pharmacopœia, or of the former Pharmacopœias of Great Britain, being made with undiluted ingredients, probably because it keeps better when thus made. To reduce it to the strength of the U. S. preparation, it required to be diluted with about four measures of distilled water. There was an advantage in this process in the use of ammonia instead of its carbonate; as the difficulty of ascertaining the precise point of saturation arising from carbonic acid was avoided; but in this solution, as in the neutral mixture, a great benefit remedially is gained by the presence of that acid, which reconciles the stomach to the medicine, and sometimes even allays vomiting in febrile diseases. With this view of the subject, it is better to use the carbonate of ammonia; and the change has been made in the present Br. Pharmacopœia.

Properties. Solution of acetate of ammonia, when made of pure materials, is a limpid and colourless liquid without smell. Its taste is saline, and resembles that of a mixture of nitre and sugar. When it contains an excess of alkali, its

taste is bitterish. It should be freshly prepared at short intervals; as its acid becomes decomposed, and a portion of carbonate of ammonia is generated. As formerly prepared, under the name of *spiritus Mindereri*, it was made from the impure carbonate of ammonia containing animal oil, which modified the preparation by giving rise to a portion of ammoniacal soap. When pure it is not coloured by hydrosulphuric acid, nor precipitated by chloride of barium. Nitrate of silver precipitates crystals of acetate of silver, soluble in water, and especially in nitric acid. An insoluble precipitate with this test is chloride of silver, and shows the presence of muriatic acid. Potassa disengages ammonia; sulphuric acid, acetous vapours. When evaporated to dryness, the residue is wholly dissipated by heat with the smell of ammonia. It is incompatible with acids, the fixed alkalies and their carbonates, lime-water, magnesia, sulphate of magnesia, corrosive sublimate, the sulphates of iron, copper, and zinc, and nitrate of silver. When it contains free carbonic acid, it produces with the acetate or subacetate of lead a precipitate of carbonate of lead, which, being mistaken for the sulphate, has sometimes led to the erroneous conclusion that sulphuric acid was present in the distilled vinegar, when this has been employed. Acetate of ammonia is a salt of difficult crystallization, and very deliquescent. When perfect it probably has an alkaline reaction, like the acetates of potassa and soda. It may be obtained by sublimation from a mixture of equal parts of dry acetate of potassa or of lime, and muriate of ammonia. It consists of one eq. of acetic acid 51, and one of ammonia 17 = 68, with seven eqs. of water 63, when crystallized. It may be viewed as acetate of oxide of ammonium, containing 6 eqs. of water.

Medical Properties and Uses. Solution of acetate of ammonia is a valuable diaphoretic, much employed in febrile and inflammatory diseases. According to the indications to be answered by its use, it is variously combined with nitre and antimonials, camphor and laudanum. If, instead of promoting its determination to the skin by external warmth, the patient walk about in a cool air, its action will be directed to the kidneys. In large doses, it is said to relieve painful menstruation. It is sometimes used externally as a discutient. Mr. Brande speaks of it as very useful in mumps, applied hot upon a piece of flannel. In the hydrocele of children, it is strongly recommended by Dr. Maushner, applied by means of compresses kept constantly moist. Mixed in the quantity of a fluidounce with seven fluidounces of rose-water, and two fluidrachms of laudanum, it forms a useful collyrium in chronic ophthalmia. The late Dr. A. T. Thomson used it as a lotion with good effect in porrigo affecting the scalp. The dose of the U. S. preparation is from half a fluidounce to a fluidounce and a half, every three or four hours, mixed with water and sweetened with sugar. It proves sometimes very grateful to febrile patients, when prescribed with an equal measure of carbonic acid water. In the present Br. Pharmacopœia the dose is stated at from two to six fluidrachms. B.

LIQUOR AMMONIÆ CITRATIS. *Br.* *Solution of Citrate of Ammonia.*

"Take of Citric Acid *three ounces* [avoirdupois]; Strong Solution of Ammonia *two fluidounces and three-quarters* [Imperial measure], or *a sufficiency*; Distilled Water *one pint* [Imp. meas.]. Dissolve the Citric Acid in the Water and add the Solution of Ammonia until the solution is neutral to test paper." *Br.*

This may be used for the same purposes as the preceding in the dose of from two to six fluidrachms. W.

LIQUOR ANTIMONII CHLORIDI. *Br.* LIQUOR ANTIMONII TERCHLORIDI. *Br.* 1864. *Solution of Chloride of Antimony. Solution of Terchloride of Antimony.*

"Take of Black Antimony *one pound* [avoirdupois]; Hydrochloric Acid *four pints* [Imperial measure]. Place the Black Antimony in a porcelain vessel; pour upon it the Hydrochloric Acid, and, constantly stirring, apply to the mixture, beneath a flue with a good draught, a gentle heat, which must be gradually augmented as the evolution of gas begins to slacken, until the

liquid boils. Maintain it at this temperature for fifteen minutes; then remove the vessel from the fire, and filter the liquid through calico into another vessel, returning what passes through first, that a perfectly clear solution may be obtained. Boil this down to the bulk of two pints [Imp. meas.], and preserve it in a stoppered bottle." *Br.*

When tersulphuret of antimony is dissolved with the aid of heat in muriatic acid, a double decomposition takes place, resulting in the formation of terchloride of antimony and hydrosulphuric acid (sulphuretted hydrogen), which gives rise to effervescence. As this gas is exceedingly offensive and deleterious, the materials, during the reaction, are directed to be placed under a flue with a good draught. When the reaction is over, the resulting aqueous solution of terchloride, after having been strained, is boiled down to a determinate volume.

Properties. Solution of chloride of antimony is a transparent, pale-yellow, dense liquid, possessing caustic properties. When of a deep-red colour, it is impure from the presence of iron. Its sp. gr., concentrated to the extent directed in the Br. Pharmacopœia, is 1·470. "A little of it dropped into water gives a white precipitate, and the filtered solution lets fall a copious deposit on the addition of nitrate of silver. If the white precipitate formed by water be treated with sulphuretted hydrogen it becomes orange-coloured." (*Br.*) These reactions show that it contains antimony and chlorine. A fluidrachm of it, mixed with four fluidounces of water in which is dissolved a quarter of an ounce (avoirdupois) of tartaric acid, forms a clear solution, from which sulphuretted hydrogen throws down an orange precipitate (tersulphuret of antimony), weighing, when washed and dried at 212°, at least 22 grains. (*Br.*) When it is distilled, water, the excess of muriatic acid, and any tersulphuret of arsenic that may happen to be present, are first expelled, and afterwards the terchloride volatilizes. The pure terchloride may be obtained by changing the receiver, as soon as the distilled product concretes on cooling. Pure terchloride of antimony, called by the earlier chemists *butter of antimony*, is a white, readily fusible solid, of the consistence of butter, deliquescent and powerfully caustic, and volatilizable under an obscure red heat. It was formerly used in medicine as a caustic. It usually acts without causing much pain or inflammation; and, after the separation of the eschar, a clean, healthy ulcer is left.

Solution of terchloride of antimony was a new officinal of the Dublin Pharmacopœia of 1850, and is probably retained in the British not as a therapeutic agent, but simply as a source of the officinal oxide of antimony.

Off. Prep. Antimonii Oxidum, *Br.* B.

LIQUOR ARSENICI ET HYDRARGYRI IODIDI. *U.S. Solution of Iodide of Arsenic and Mercury. Solution of Hydriodate of Arsenic and Mercury. Donovan's Solution.*

"Take of Iodide of Arsenic, Red Iodide of Mercury, each, *thirty-five grains;* Distilled Water *half a pint.* Rub the Iodides with half a fluidounce of the Water, and, when they have dissolved, add the remainder of the Water, and filter through paper." *U.S.*

This solution was introduced to the notice of the medical profession in 1839, by Mr. Donovan, of Dublin, as a therapeutic agent combining the medical virtues of its three ingredients, and was adopted as an officinal preparation in the U. S. and Dublin Pharmacopœias of 1850. The former has retained it in the present edition; but, on the absorption of the latter in the British Pharmacopœia, it was discarded. The formula of the U. S. Pharmacopœia is the simplified one of Prof. Procter, which consists essentially in dissolving equal weights of the teriodide of arsenic and biniodide (red iodide) of mercury in a measured quantity of distilled water. The proportion of equal weights corresponds nearly to single equivalents of the component iodides. The Dublin formula was more complicated. In it the proper quantities of arsenic, mercury, and iodine were caused to unite by first rubbing them together with alcohol, and then boiling the product with distilled water, which was afterwards added, so as to give the whole a determinate bulk. The iodides of arsenic and mercury, formed by the tritura-

tion, were assumed by Mr. Donovan to become, by solution, hydriodates severally of arsenious acid (white oxide of arsenic), and of deutoxide of mercury (red precipitate).

Properties. This solution has a pale-yellow colour, and a slightly styptic taste. Sometimes, however, the colour is orange-yellow, owing to the presence of free iodine. This may be neutralized by rubbing the solution with a little metallic mercury or arsenic, in fine powder, and the proper hue thus restored. The solution is incompatible with laudanum and the soluble salts of morphia. On the supposition that it is an aqueous solution of iodides, it will contain them in the proportion of one eq. of teriodide of arsenic 453·9 to one of biniodide of mercury 452·6, which are nearly equal weights. On the theory of their conversion into hydriodates by solution, five eqs. of water 45 would be required, three for the arsenical teriodide, and two for the mercurial biniodide; and the result would be one eq. of arsenious acid 99, one of deutoxide of mercury 216, and five of hydriodic acid 636·5, the latter containing five eqs. of iodine 631·5. The solution here supposed would contain about two and one-sixth times as much deutoxide of mercury as of arsenious acid.

Medical Properties. This preparation has been found decidedly useful as an alterative in various diseases of the skin, such as the different forms of psoriasis, impetigo, porrigo, lepra, pityriasis, lupus, and venereal eruptions, both papular and scaly. In support of its efficacy in these affections, Mr. Donovan has adduced the testimony of a number of respectable practitioners, who have communicated to him the results of their experience. The disease in some of the cases cured had existed for several years. Many American physicians also have used it advantageously in cutaneous diseases, and found more prompt effects from it than from the remedies usually resorted to. The dose is from five to twenty drops three times a day, given preferably in distilled water. The latter dose contains the twenty-fourth of a grain of arsenious acid, a little over the twelfth of a grain of deutoxide of mercury, and about a quarter of a grain of iodine. Dr. E. I. Taylor, of New York, who has employed it in many cases, never exceeded five drops, three times a day. Sometimes the medicine deranges the stomach, confines the bowels, and causes headache, giddiness, and confusion of mind. When these effects are produced, it must be laid aside, and a purgative administered. After an interval varying from ten days to three weeks, it may be resumed, but in a smaller dose. The treatment must often be persevered in for several months. Sometimes the medicine produces moderate salivation. The solution, diluted with an equal bulk of water, has occasionally been used with advantage as an application to the ulcers or eruptions, at the same time that it was given internally. (See three papers by Mr. Donovan, contained in the *Dublin Journal of Medical Science* for Nov. 1839, Sept. 1840, and Nov. 1842.) B.

LIQUOR ARSENICI HYDROCHLORICUS. *Br. Hydrochloric Solution of Arsenic.*

"Take of Arsenious Acid, in powder, *eighty grains;* Hydrochloric Acid *two fluidrachms;* Distilled Water *a sufficiency.* Boil the Arsenious Acid with the Hydrochloric Acid, and four [fluid]ounces of the Water until it is dissolved, then add Distilled Water to make the bulk up to one pint [Imperial measure].

The hydrochloric solution of arsenic is a colourless liquid, of the sp. gr. 1·009, and an acid reaction. With sulphuretted hydrogen it gives a bright-yellow precipitate of sulphuret of arsenic. One fluidounce of it (441·5 grains), boiled for five minutes with twenty grains of bicarbonate of soda, and then diluted with six fluidounces of distilled water to which a little mucilage of starch has been added, does not give with the *volumetric solution of iodine* a permanent blue colour until 808 grain-measures have been added, corresponding to four grains of arsenious acid in one fluidounce. *Br.*

The medical properties of this solution are the same as those of Fowler's solution, with which it corresponds in strength, being nearly three times as strong as the former London solution of chloride of arsenic. The dose is from two to eight minims. W.

LIQUOR ATROPIÆ. *Br. Solution of Atropia.*

"Take of Atropia *four grains;* Rectified Spirit *one fluidrachm;* Distilled Water *seven fluidrachms.* Dissolve the Atropia in the Spirit, and add this gradually to the Water, shaking them together." *Br.*

For the effects of this solution, see Atropia. If given internally the dose to begin with should not exceed four minims. But, as we have in the extract of belladonna a preparation which may generally be depended on for obtaining the effects of the medicine, it seems hardly advisable to make use internally of so powerful and dangerous a preparation. It may be applied to the eye for dilating the pupil, or injected into the subcutaneous tissue for obtaining the effects of belladonna on the system. W.

LIQUOR ATROPIÆ SULPHATIS. *Br. Solution of Sulphate of Atropia.*

"Take of Sulphate of Atropia *four grains;* Distilled Water *one fluidounce* [Imperial measure]. Dissolve." *Br.*

This is a convenient form for administering atropia. The solution is of the same strength, and is used for the same purposes as the preceding. W.

LIQUOR BARII CHLORIDI. *U. S. Solution of Chloride of Barium. Solution of Muriate of Baryta.*

"Take of Chloride of Barium *a troyounce;* Distilled Water *three fluidounces.* Dissolve the Chloride in the Distilled Water, and filter through paper." *U. S.*

This has been omitted from the list of preparations in the British Pharmacopœia, but is contained in the Appendix as a test solution; having the strength of one ounce to ten fluidounces.

Chloride of barium, not being used in the solid state, is here dissolved for convenience in prescribing. The solution is nearly saturated, and is probably too strong for convenient use. It should be limpid and colourless; and, to make it so, the salt in crystals, and not in powder, should be employed.

Medical Properties and Uses. This solution is deobstruent and anthelmintic, and in large doses poisonous; its action, according to some, being analogous to that of arsenic. It was introduced into practice by Dr. Crawford as a remedy for cancer and scrofula. Its value in the latter disease has been insisted on by Hufeland. This physician considers it to act more particularly on the lymphatic system, in the irritated states of which he esteems it a valuable remedy. Hence he recommends it in the scrofulous affections of delicate and irritable organs, such as the eyes, lungs, &c. In the commencement of scrofulous phthisis, he views it as one of the best remedies to which we can have recourse. It is also employed in diseases of the skin, in ulcers, and ophthalmia. The dose for an adult is about five drops, given twice or thrice a day, and gradually but cautiously increased, until it produces nausea, or some other sensible impression. When taken in an overdose it causes violent vomiting and purging, vertigo, and other dangerous symptoms. To combat its poisonous effects, recourse must be had immediately to a weak solution of sulphate of magnesia, which acts by converting the poison into the insoluble sulphate of baryta. If vomiting does not come on, it should be induced by tickling the fauces, or by the administration of an emetic. A case of poisoning by three drachms of the solid salt, taken by mistake for sulphate of magnesia, was successfully treated with dilute sulphuric acid and castor oil, by Dr. C. Wolf, a German physician. The chief symptoms were tormina and vomiting, weak and irregular pulse, cold extremities, weak voice, want of muscular power in the hands and feet, and paralysis of the left eyelid. B.

LIQUOR BISMUTHI ET AMMONIÆ CITRATIS. *Br. Solution of Citrate of Bismuth and Ammonia.*

"Take of Purified Bismuth *four hundred and thirty grains;* Nitric Acid *two fluidounces* [Imperial measure]; Citric Acid *two ounces* [avoirdupois];

Solution of Ammonia, Distilled Water, of each, *a sufficiency.* Mix the Nitric Acid with a [fluid]ounce of Distilled Water, and add the Bismuth in successive portions. When effervescence has ceased apply for ten minutes a heat approaching that of ebullition, and decant the solution from any insoluble matter that may be present. Evaporate the solution until it is reduced to two fluidounces; then add the Citric Acid previously dissolved in four [fluid]ounces of Distilled Water, and afterwards the Solution of Ammonia in small quantities at a time until the precipitate formed is redissolved, and the solution is neutral or slightly alkaline to test paper. Dilute with Distilled Water to the volume of one pint [Imp. meas.]." *Br.*

This is not the formula that we would recommend for the preparation of the "*Solution of Citrate of Bismuth and Ammonia,*" placed at the head of this article. Indeed, the product of the formula is not the substance it purports to be; but probably nitrate of bismuth held in solution by means of citrate of ammonia. The first step is to make a very concentrated solution of nitrate of bismuth, to which is then added a solution of citric acid, containing water enough to cause a partial precipitate of subnitrate of bismuth, which is dissolved again by the addition of ammonia. This neutralizes the citric acid, and the resulting citrate of ammonia holds the re-formed nitrate of bismuth in solution; or the two acids may divide the two bases between them, forming a mixture of nitrate and citrate of ammonia and bismuth. At all events, the nitric acid is retained in the preparation; and, as all its salts are much more irritating than the corresponding salts of citric acid, we have a preparation likely to irritate the stomach, instead of the mild insoluble salts of bismuth which it is intended to represent, or the mild citrate of bismuth and ammonia which it purports to be. In all other processes we have seen, pains are taken to get rid of the nitric acid.

Though the insolubility of the officinal preparations of bismuth is probably one of the causes of their efficiency in certain diseases of the alimentary mucous membrane, enabling them by deposition on the surface to protect it against irritation from the contents of the stomach and bowels, yet a soluble form of the metal has been sought for, in the hope that it might, in this condition, operate on the *system* in smaller doses, and with greater certainty and efficiency. This want was to some extent supplied by a secret preparation, made and sold by Mr. Schacht, of Clifton, England, which, under the name of *Liquor Bismuthi*, has, for the last eight or nine years, been used to a considerable extent in Great Britain. Mr. Ch. R. C. Tichborne, having analyzed the liquid, and found it to contain oxide of bismuth, ammonia, and citric acid, announced the discovery at a meeting of the Pharmaceutical Society, when Mr. Schacht, being present, acknowledged the correctness of the analysis, stating, at the same time, that he had never made a secret of the composition of his solution to medical practitioners, and that a fluidrachm of his liquid contained one grain of the teroxide. (*Pharm. Journ.*, Jan. 1864, p. 301.) A formula for the preparation was given by Mr. Tichborne, which, however, on repeated trial by Mr. N. Gray Bartlett, of Chicago, proved to be impracticable. After numerous experiments, Mr. Bartlett succeeded in making a solution which had all the desired qualities, and a formula for which he published in the *American Journal of Pharmacy* for January, 1865. He first prepares a *citrate of bismuth* by dissolving a *troyounce* of the subcarbonate of bismuth in 720 *grains* of nitric acid, diluting the solution after effervescence has ceased with *a fluidounce and a half* of distilled water gradually introduced, and then adding this solution, slowly and with constant stirring, to another solution made by dissolving 600 *grains* of citrate of potassa in *two pints* of distilled water. By an interchange of principles, nitrate of potassa and citrate of bismuth are formed, the latter of which, being insoluble, is precipitated, and is obtained by throwing the whole upon a filter, thoroughly washing the salt with distilled water, and then drying it on bibulous paper with a gentle heat. The next step is to prepare the *citrate of bismuth and ammonia.* This is done by rubbing

the citrate of bismuth with sufficient distilled water to make a paste, and adding to this gradually, and with constant trituration, stronger water of ammonia until the citrate is dissolved, care being taken to avoid an excess of ammonia. The solution is now filtered, and spread on glass to dry.

Various modifications of Mr. Bartlett's process have been suggested, though it may be doubted whether any one, on the whole, is preferable to the original. Besides processes offered by Mr. T. P. Blunt and Mr. Tichborne, in England, two pharmaceutists of this country, Mr. A. E. Ebert, of Chicago, and Mr. Geo. F. H. Markoe, of Boston, have each proposed a modification of Mr. Bartlett's process, the former in a communication to the *Am. Journ. of Pharm.* (Jan. 1866, p. 1); the latter in a paper published in the *Proceedings of the Am. Pharm. Association* for 1868, copied in the *Am. Journ. of Pharm.* (March, 1869, p. 151), to which the reader is referred for details. In Mr. Ebert's formula the solution of nitrate of bismuth is decomposed by caustic potassa in the presence of citric acid, instead of the citrate of potassa already formed; in Mr. Markoe's, crystallized carbonate of soda is substituted for the caustic alkali, to which various objections exist. After precipitating the solution of nitrate of bismuth to which citric acid has been added, with carbonate of soda, washing the precipitate to get rid of the nitrate of soda, and dissolving the residue of the precipitate in water of ammonia, Mr. Markoe completes the process by determining the proportion of teroxide of bismuth contained in the solution, and then diluting the liquid so that each fluidrachm shall contain one grain of teroxide. It is obvious that this process requires for its proper execution the practised pharmaceutist.

Citrate of bismuth and ammonia, obtained by Mr. Bartlett's process, is in fine, glossy, translucent, colourless scales, of a slightly acidulous, somewhat metallic, not disagreeable taste, very soluble in water, but not deliquescent, and of an acid reaction. From an analysis by Mr. Bartlett, it appears to consist of one eq. of teroxide of bismuth 237, one of ammonia 26, and one of citric acid 165, with 5 eqs. of water 45 = 473; and its formula is $BiO_3\,NH_4O,C_{12}H_5O_{11}+5HO$.

There is no occasion for a permanent solution of this salt, as it may at any time be dissolved when wanted for use. But, as it is in the liquid form that it has obtained its present reputation, we give a formula for a permanent solution prepared by Mr. Bartlett. Dissolve 260 *grains* of citrate of bismuth and ammonia in *fourteen fluidounces* of distilled water, neutralize the solution with water of ammonia, and add *two fluidounces* of alcohol. The solution of the salt without addition is liable to spontaneous decomposition; but, in the opinion of Mr. Bartlett, it is completely protected by the ammonia and alcohol, so that in this state it will keep indefinitely. The uses of this preparation are essentially the same as those of the insoluble salts, except in so far as the latter are connected with the condition of insolubility. (See *Bismuthi Subnitras.*) The dose of the solid citrate is two grains, that of the solution a fluidrachm. For further particulars in regard to the preparation of the salt and its solution, the reader is referred to Mr. Bartlett's paper in the *Am. Journ. of Pharm.* (Jan. 1865) already noticed. W.

LIQUOR CALCII CHLORIDI. *U. S. Solution of Chloride of Calcium. Solution of Muriate of Lime.*

"Take of Marble, in small pieces, *six troyounces;* Muriatic Acid *twelve troyounces;* Distilled Water *a sufficient quantity.* Mix the Acid with half a pint of Distilled Water, and gradually add the Marble. Towards the close of the effervescence apply a gentle heat, and, when the action has ceased, pour off the clear liquid and evaporate to dryness. Dissolve the residue in one and a half times its weight of Distilled Water, and filter through paper." *U. S.*

This is not included among the preparations of the British Pharmacopœia, but is placed in the Appendix as a test solution, of the strength of one ounce to ten fluidounces.

By the above process chloride of calcium is first formed, and then dissolved in a certain proportion of water. The solution contains 1 part of the chloride in about 2·5 parts.

The solution of chloride of calcium has a disagreeable, bitter, acrid taste. It is decomposed by sulphuric acid and the soluble sulphates; by potassa, soda, and their carbonates; by carbonate of ammonia, tartrate of potassa and soda, nitrate of silver, nitrate and acetate of mercury, and acetate of lead. The mode of preparing chloride of calcium, and its chemical properties, are detailed under the head of *Calcii Chloridum* in the first part of this work.

Medical Properties and Uses. Chloride of calcium is considered tonic and deobstruent, and is said to promote the secretion of urine, perspiration, and mucus. It was first brought into notice as a remedy by Fourcroy, and was at one time much used in scrofulous diseases and goitre. It still continues in favour with some physicians, but is less employed than formerly. It has been especially recommended in tabes mesenterica. Cazenave has employed it advantageously in chronic eczema and impetigo, connected with a lymphatic temperament. When too largely taken, it sometimes occasions nausea, vomiting, and purging, and in excessive doses may even produce fatal effects; but it is a much safer remedy than chloride of barium, which has been recommended in the same complaints. The dose of the solution is from thirty minims or drops to a fluidrachm, to be repeated twice or three times a day, and gradually increased to two, three, or even four fluidrachms. It may be given in milk or sweetened water.

Off. Prep. Calcis Carbonas Præcipitata, *U. S.* W.

LIQUOR CALCIS. *U. S.*, *Br.* *Solution of Lime.* *Lime-water.*

"Take of Lime *four troyounces;* Distilled Water *eight pints.* Upon the Lime, first slaked with a little of the Distilled Water, pour the remainder, and stir them together. Then immediately cover the vessel, and set it aside for three hours. Keep the solution, together with the undissolved Lime, in a well-stopped bottle, and pour off the clear liquor when wanted for use. Water free from saline or other obvious impurity, though not distilled, may be employed in this process." *U. S.*

"Take of Slaked Lime *two ounces* [avoirdupois]; Distilled Water *one gallon* [Imperial measure]. Put the Lime into a stoppered bottle containing the Water; and shake well for two or three minutes. After twelve hours the excess of lime will have subsided, and the clear solution may be drawn off with a siphon as it is required for use, or transferred to a green-glass bottle furnished with a well-ground stopper." *Br.*

A solution of lime in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water. According to both Pharmacopœias, the solution is to be kept in bottles with a portion of undissolved lime, which causes it always to be saturated whatever may be the temperature, and to whatever extent it may be exposed to the air. If care be taken to have a considerable quantity of the solution in the bottle, and to avoid unnecessary agitation, the upper portion will always remain sufficiently clear for use. The employment of distilled water as the solvent may seem a useless refinement; and it certainly is unnecessary when pure spring or river water is attainable; but in many places the common water is very impure, and wholly unfit for a preparation, one of the most frequent uses of which is to allay irritation of stomach. Water dissolves but a minute proportion of lime, and, contrary to the general law, less when hot than cold. Hence the propriety of employing cold water in the process. According to Mr. Phillips, a pint of water (the wine pint of the U. S. Pharm.) at 212° dissolves 5·6 grains of lime, at 60°, 9·7 grains, and at 32°, 11·0 grains. When a cold saturated solution is heated, a deposition of lime takes place.

Properties. Lime-water is colourless, inodorous, and of a disagreeable alkaline taste, changes vegetable blues to green, and forms an imperfect soap with oils. Exposed to the air it attracts carbonic acid, and becomes covered with a pellicle of insoluble carbonate of lime, which, subsiding after a time, is replaced by another, and so on successively till the whole of the lime is exhausted. Hence the necessity of keeping lime-water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime. "Ten fluid-

ounces of it require for neutralisation at least 200 grain-measures of the *volumetric solution of oxalic acid*, which corresponds to 5·6 grains of lime, CaO." *Br.*

Medical Properties and Uses. Lime-water is antacid, tonic, and astringent, and is very usefully employed in dyspepsia with acidity of stomach, diarrhœa, diabetes, and gravel attended with superabundant secretion of uric acid. Mixed with an equal measure of milk, which completely covers its offensive taste, it is one of the best remedies in our possession for nausea and vomiting dependent on irritability of stomach. We have found a diet exclusively of lime-water and milk to be more effectual than almost any other plan of treatment in dyspepsia accompanied with vomiting of food. In this case one part of the solution to two or three parts of milk is usually sufficient. Lime-water is also thought to be useful by dissolving the intestinal mucus in cases of worms, and in other complaints connected with an excess of this secretion. Externally it is employed as a wash in tinea capitis and scabies, as an application to foul and gangrenous ulcers, as an injection in leucorrhœa and ulceration of the bladder or urethra, and, mixed with linseed or olive oil, as a liniment in burns and scalds. Having been found to possess the property of dissolving false-membrane, it was naturally employed as a local remedy in pseudomembranous croup. Dr. B. W. Wilson, of Philadelphia, reported, in the *Medical and Surgical Reporter* (Aug. 27, 1867, p. 355), several cases in which the remedy was used successfully; and other instances have been since recorded of cures of undoubted cases of the disease. There are two methods of applying the remedy; one by directing lime-water spray, produced by the atomizer, so that it shall be inhaled by the patient; the other, which is recommended by Dr. Wilson, by causing the patient to inhale freely the vapours arising from lime undergoing the process of slaking with water. The dose is from two to four fluidounces several times a day. When employed to allay nausea, it is usually given in the dose of a tablespoonful mixed with the same quantity of new milk, and repeated at intervals of half an hour, an hour, or two hours. If too long continued it debilitates the stomach.

LIQUOR CALCIS CHLORATÆ. *Br. Solution of Chlorinated Lime.*

"Take of Chlorinated Lime *one pound* [avoirdupois]; Distilled Water *one gallon* [Imperial measure]. Mix well the Water and the Chlorinated Lime by trituration in a large mortar, and, having transferred the mixture to a stoppered bottle, let it be well shaken several times for the space of three hours. Pour out now the contents of the bottle on a calico filter, and let the solution which passes through be preserved in a stoppered bottle. The sp. gr. of this liquid is 1·035." *Br.*

For the properties and uses of this preparation, see *Calx Chlorinata*, page 193. The British Pharmacopœia gives the following test of its strength. "Sixty grains mixed with twenty grains of iodide of potassium dissolved in four fluidounces of water, when acidulated with two fluidrachms of hydrochloric acid, gives a red solution, which requires for the discharge of its colour 500 grain-measures of the *volumetric solution of hyposulphite of soda*, corresponding to 13 grains of available chlorine in a fluidounce." This determines its strength in chlorine, by determining the quantity of iodine which the chlorine contained in it is capable of separating from iodide of potassium. Notwithstanding, however, that a test of its character is thus given by the Pharmacopœia, its strength must vary according to the quality of the chlorinated lime employed. It is one of the best antidotes for hydrosulphuric acid, hydrosulphate of ammonia, sulphuret of potassium, and hydrocyanic acid. The dose for internal use is from twenty minims to a fluidrachm. For external application the solution may be diluted with twice its bulk of water, or may be used of the full strength in some cutaneous affections. W.

LIQUOR CALCIS SACCHARATUS. *Br. Saccharated Solution of Lime.*

"Take of Slaked Lime *one ounce* [avoirdupois]; Refined Sugar, in powder, *two ounces* [avoird.]; Distilled Water *one pint* [Imperial measure]. Mix the Lime and the Sugar by trituration in a mortar. Transfer the mixture to a bottle containing the Water, and, having closed this with a cork, shake it occasionally for a few hours. Finally separate the clear solution with a siphon, and keep it in a stoppered bottle. The sp. gr. is 1·052. One fluidounce (460·2) requires for neutralisation 254 grain-measures of the *volumetric solution of oxalic acid*, which corresponds to 7·11 grains of lime in one fluidounce." *Br.*

Lime appears to form a combination with sugar which is much more soluble than the lime itself, so that in this way we can obtain a much stronger solution of lime than by the instrumentality of water alone. This preparation may be used in diarrhœa with acidity, in vomiting, in affections of the urinary organs requiring antacid treatment, and for all other therapeutical purposes to which lime is applied. The dose equivalent to a fluidounce of lime-water is about a fluidrachm.* W.

LIQUOR FERRI CITRATIS. *U.S. Solution of Citrate of Iron.*

"Take of Citric Acid, in coarse powder, *five troyounces and three hundred and sixty grains;* Solution of Tersulphate of Iron *a pint;* Water of Ammonia, Distilled Water, each, *a sufficient quantity.* Dilute the Solution of Tersulphate of Iron with two pints of Distilled Water, add a slight excess of Water of Ammonia, with constant stirring, transfer the precipitate formed to a muslin strainer, and wash it with water until the washings are nearly tasteless. When the precipitate is drained, put half of it in a porcelain capsule on a water-bath, heated to 150°, add the Citric Acid, and stir the mixture until the precipitate is nearly dissolved. Then add so much of the reserved precipitate as may be necessary fully to saturate the Acid. Lastly, filter the liquid, and evaporate it, at a temperature not exceeding 150°, until it is reduced to the measure of a pint." *U. S.*

* *Syrup of Lime. Saccharate of Lime.* Under the latter name a preparation has been introduced into notice, made by saturating pure syrup with lime, and filtering. The sugar forms a soluble compound with the lime, large quantities of which are dissolved by the syrup. The syrup remains perfectly transparent, and is in no degree disturbed by dilution with water. It has a decidedly alkaline and even caustic taste, and should always be largely diluted when administered. It was first prepared by M. Beral; and its practical use was originally suggested by Dr. Capitaine, of Paris. Trousseau has employed it in the chronic diarrhœa of infants, and recommends it as an addition, in very small proportion, to the milk employed as a diet for children liable to this complaint. For this purpose he adds about eight grains of the syrup to the quart of milk. He gives the saturated syrup of lime to a child in the quantity of fifteen or thirty grains in the course of the day; to an adult, in five times the quantity. (*Trait. de Thérap.*)—*Note to the tenth edition.*

Dr. E. R. Squibb gives the following formula for the preparation of *Syrup of Lime.* Take of good, clean, well-burned lime 400 grains; dry, granulated, white sugar 2300 grains. Triturate well together in a mortar, and then add the powder to f℥viij of boiling water contained in a proper vessel (well tinned iron or bright copper answers) and boil the mixture with constant stirring for five minutes. Then dilute to two parts with cold water, and filter through white paper. Finally evaporate to whatever consistence may be desired. If reduced to a pint, each fluidounce will contain 24 grains of caustic lime; and the syrup will be about as dense as can be conveniently dispensed. If desired, the evaporation may be carried to dryness, care being observed to avoid burning by constant stirring, till a little taken from the melted mass will crumble between the fingers on cooling. The contents of the vessel may then be allowed to cool, and when dry and solid should be rubbed into fine powder, which will contain from 8 to 10 per cent. of lime.

Dr. Charles E. Buckingham, of Boston, says, in relation to this syrup, that it should not be taken either in pill or dissolved in water, as it will occasion nausea or produce a caustic effect. He gives it in milk, and considers thirty drops every three hours as a sufficient dose. He has never known it to cause alkaline urine. (*Boston Med. and Surg. Journ.*, April 4, 1867, p. 186.) Dr. Buckingham has used the syrup of lime with great success in acute rheumatism; twelve cases having been treated with this remedy exclusively, with an average duration of ten days. (*Ibid.*, April 11, 1867, p. 105.) Others have tried the remedy with a similar experience. (*Note to the thirteenth edition.*)

In this process, the hydrated sesquioxide of iron is first obtained by treating solution of the tersulphate with ammonia, and is then combined, with the aid of heat, with the citric acid, thus forming a solution of the citrate of the sesquioxide of iron, consisting of one eq. of acid and one of sesquioxide. It might appear, from the phraseology of the process, that, in the direction to add the citric acid to the precipitated sesquioxide, the addition of water to hold the resulting citrate in solution had been omitted; but the fact is, that the precipitate, even after draining, retains mechanically quite sufficient water for the purpose, so much, indeed, that evaporation is necessary at the end of the process to reduce the bulk to the required standard. The temperature is limited to 150°, because, though a moderate heat promotes the solution, a high degree of it diminishes the solubility of the oxide, and thus interferes with the process.

The solution has a deep reddish-brown colour, and a slight not unpleasant chalybeate taste. It keeps for a long time without change, and answers admirably well for preparing solid citrate of iron, and the chalybeate salts containing it, and for introducing it into extemporaneous mixtures. Each fluidounce of it contains half a troyounce of citrate of iron. It may be given, for the general purposes of the ferruginous preparations, in the dose of ten minims, equivalent to five grains of the salt, several times a day.

LIQUOR FERRI NITRATIS. *U.S.* Liquor Ferri Pernitratis. *Br. Solution of Nitrate of Iron. Solution of Pernitrate of Iron. Solution of Ternitrate of Sesquioxide of Iron.*

"Take of Iron, in the form of wire, and cut in pieces, *two troy ounces and a half:* Nitric Acid [sp. gr. 1·42] *five troyounces;* Distilled Water *a sufficient quantity* Mix the Iron with twelve fluidounces of Distilled Water in a wide-mouthed bottle, and add to the mixture, in small portions at a time, with frequent agitation, three troyounces of the Nitric Acid, previously mixed with six fluidounces of Distilled Water, moderating the reaction by setting the vessel in cold water, in order to prevent the occurrence of red fumes. When the effervescence has nearly ceased, agitate the solution with the undissolved iron until a portion of the liquid, on being filtered, exhibits a pale-green colour. Then filter the liquid, and, having poured it into a capacious porcelain capsule, heat it to the temperature of 130°, and add the remainder of the Nitric Acid. When the effervescence has ceased, continue the heat until no more gas escapes, and then add sufficient Distilled Water to bring the liquid to the measure of thirty-six fluidounces." *U. S.*

"Take of fine Iron Wire, free from rust, *one ounce* [avoirdupois]; Nitric Acid *four and a half fluidounces* [Imperial measure]; Distilled Water *a sufficiency.* Dilute the Nitric Acid with sixteen [fluid]ounces of the Water, introduce the Iron Wire into the mixture, and leave them in contact until the metal is dissolved, taking care to moderate the action, should it become too violent, by the addition of a little more Distilled Water. Filter the solution, and add to it as much Distilled Water as will make its bulk one pint and a half [Imp. meas.]. The specific gravity is 1·107." *Br.*

The above U.S. formula has been substituted for the one adopted in the second edition of the Pharmacopœia, published in Dec. 1855, which upon trial was found by Prof. Procter to have defects, which, it is believed, have been corrected in the present. In the existing formula, nitric acid (sp. gr. 1·42), diluted, is gradually added to an *excess* of iron, mixed with water, so as to ensure the production of the mononitrate of protoxide of iron, which is filtered from the excess of iron. To this is added a quantity of nitric acid, equal to two-thirds of that originally directed, which converts the mononitrate of the protoxide into the ternitrate of the sesquioxide, attended with a violent effervescence of red hyponitric acid vapours. The preparation is finished by giving it a determinate bulk by the addition of water. In this process, the two portions of nitric acid used are correctly adjusted to produce the intended result. Thus, six eqs. of mononi-

trate, containing six eqs. of nitric acid, require exactly four additional eqs. of acid to effect the conversion; one eq. of the additional acid being expended in converting the six eqs. of protoxide into three eqs. of sesquioxide, and the three remaining eqs. in completing three eqs. of ternitrate.*

The peculiarity of the above process is the addition of the nitric acid in two portions at different times; the first portion not larger than is necessary to form the nitrate of the protoxide, and the second sufficient to convert this into the ternitrate of the sesquioxide. The object gained by this procedure seems to be to obviate the tendency which nitric acid has to sesquioxidize a larger portion of iron than can be neutralized by what remains of the acid, unless this be employed in such a proportion as to endanger an excess in the resulting solution. By this excess of sesquioxide, a subsalt is formed, which is not readily held in solution with the neutral sesquinitrate, and is therefore apt to be slowly deposited from the officinal preparation, unless care is taken to prevent its production.

The U. S. solution of nitrate of iron has a sp. gr. between 1·060 and 1·070, a pale-amber colour, and a strong astringent acid taste. It contains no protoxide of iron, and does not give a blue precipitate with ferridcyanide of potassium. A fluidounce of it, on the addition of an excess of ammonia, yields a reddish-brown precipitate, which, when washed, dried, and ignited, weighs between eight and ten grains. (*U. S.*) The British preparation is of a reddish-brown colour, of the sp. gr. 1·107, and gives a blue precipitate with the yellow prussiate of potash [ferrocyanide of potassium]. The precipitate obtained from a fluidrachm of it by the addition of an excess of ammonia, when washed, dried, and incinerated, weighs 2·6 grains. (*Br.*) It is, therefore, about twice as strong as the U. S. solution.

Ternitrate of sesquioxide of iron, as described by Mr. J. M. Ordway, of Massachusetts, is in the form of oblique rhombic prisms, which are either colourless, or of a delicate lavender colour. It is somewhat deliquescent, very soluble in water, and sparingly soluble in nitric acid. It consists of three eqs. of nitric acid, one of sesquioxide of iron, and eighteen of water. (*Silliman's Journ.*, Jan. 1850.) S. Hausmann found only twelve eqs. of water. (*Chem. Gaz.*, June 1, 1854.)

Medical Properties. This solution was introduced to the notice of the profession by Mr. William Kerr, in 1832. Its virtues are those of a tonic and astringent. Dr. R. J. Graves, of Dublin, praises it as a remedy in chronic diarrhœa, especially when occurring in delicate and nervous women, in which there is no thirst, redness of tongue, tenderness of the abdomen on pressure, or other indi-

* Prof. Procter has proposed the following formula for a *syrup of the nitrate of protoxide of iron*, a preparation considerably used, in Philadelphia, as an astringent in chronic diarrhœa. Take of Iron Wire, in pieces (card teeth), *two ounces;* Nitric Acid (sp. gr. 1·42) *three fluidounces;* Water *thirteen fluidounces;* Sugar, in powder, *two pounds.* Put the iron in a wide-mouthed bottle, kept cool by standing in cold water, and pour upon it three fluidounces of water. Then mix the acid with ten fluidounces of water, and add the mixture in portions of half a fluidounce to the iron, agitating frequently until the acid is saturated, using litmus paper. When the saturation is complete, filter the solution into a bottle containing the sugar, and marked to contain thirty fluidounces. If the whole does not measure that bulk, pass water through the filter to make up the deficiency. When all the sugar is dissolved, strain if necessary, and introduce the syrup into suitable vials, and seal them. This syrup is thick, permanent, of a light-greenish colour, perfectly transparent, neutral, and yields a greenish precipitate with ammonia. (*Am. Journ. of Pharm.*, Oct. 1851, p. 314.) Mr. W. W. D. Livermore has given a formula for a similar syrup. (*Ibid.*, p. 315.) A third formula has been proposed by Mr. Thomas Lancaster, of this city, in which the nitrate of protoxide of iron is obtained by double decomposition between nitrate of lime and sulphate of protoxide of iron. (*Ibid.*, Sept. 1854, p. 400.) These syrups should not contain an excess of acid; for if they do, they are apt to deposit, after keeping, white granular masses of grape sugar, as observed by Mr. W. Tozier, of Kingstown, Ireland, in consequence of the action of the acid upon the cane sugar. According to Mr. Joseph Laidley, of Richmond, Va., the so-called syrup of the nitrate of sesquioxide of iron is an unscientific preparation, containing protoxide if an excess of acid is avoided, and liable to let fall a precipitate of oxalate of iron when the acid is in excess. Hence Mr. Laidley believes that the only nitrate, proper to be formed into a syrup, is the nitrate of the protoxide, where alone the protective influence of sugar is required. (*Ibid.*, March, 1853, p. 97.)—*Note to the tenth and eleventh editions.*

cation of inflammation. Mr. Kerr attributed to it the property of diminishing the irritability of the intestinal mucous membrane. It is particularly applicable to the treatment of mucous diarrhœa, attended with pain, but not to cases in which ulcerations of the intestines exist. Dr. T. C. Adams, of Michigan, also reports favourably of this remedy in chronic diarrhœa, considering it, like Mr. Kerr, to act as a sedative as well as astringent. He employed it, likewise with good effect, in menorrhagia, and both internally and by injection in leucorrhœa, when occurring in pale, exsanguine, and feeble subjects. The dose, according to Dr. Graves, is seven or eight drops, gradually increased to fifteen, sufficiently diluted, given in the course of the day. Dr. Adams gave it in doses of ten drops, two, three, or four times a day, and sometimes increased it to twenty-five drops. Dr. Garrod and Mr. Squire, the two most prominent expounders of the British Pharmacopœia, state the dose of the British preparation, though twice as strong in iron as our own, at from thirty minims to a fluidrachm. Considering that a fluidrachm of the British solution contains 7·865 grains of the salt, this appears to us a very large dose; and the doses recommended by Drs. Graves and Adams would probably be safer. As an injection, Dr. Adams employed it sufficiently diluted to cause only a slight heat and smarting in the vagina. B.

LIQUOR FERRI PERCHLORIDI. *Br. Solution of Perchloride of Iron.*

"Take of Strong Solution of Perchloride of Iron *five fluidounces;* Distilled Water *fifteen fluidounces.* Mix."

This is of one-fourth the strength of the *Liquor Ferri Perchloridi* of the Br. Pharmacopœia of 1864, which is the *Liquor Ferri Perchloridi Fortior* of the present edition. It is of the same ferruginous strength as the British Tincture of Perchloride of Iron. W.

LIQUOR FERRI PERCHLORIDI FORTIOR. *Br.* Liquor Ferri Perchloridi. *Br.* 1864. *Strong Solution of Perchloride of Iron.*

"Take of Iron Wire *two ounces* [avoirdupois]; Hydrochloric Acid *twelve fluidounces;* Nitric Acid *nine fluidrachms;* Distilled Water *eight fluidounces.* Mix eight fluidounces of the Hydrochloric Acid with the Distilled Water, and in this dissolve the Iron at a gentle heat. Filter the solution, add to it the remainder of the Hydrochloric Acid and the Nitric Acid, heat the mixture briskly until, on the sudden evolution of red fumes, the liquid becomes of an orange-brown colour, then evaporate by the heat of a water-bath until it is reduced to ten fluidounces." *Br.*

By the reaction between the muriatic acid and iron a chloride of that metal is produced, which by the subsequent agency of the nitric acid is converted into the sesquichloride, or, as denominated in the Br. Pharmacopœia, the perchloride, which is held in solution by the water.

The original British formula (1864) was defective in several respects. It was intended that the conversion of the protochloride into sesquichloride should be complete; and hence the solution was described as having an orange-brown colour, and as not being precipitated by ferridcyanide of potassium, which throws down a blue precipitate with the protochloride. But it was stated by Mr. Squire that, made in accordance with the officinal directions, the solution was almost black in consequence of the presence of protochloride, and besides contained free nitric acid; the whole of that directed in the formula not being decomposed. According to the Pharmacopœia, it mixed with water and alcohol in all proportions; and it was by the addition of alcohol to it that the British tincture of the chloride was formed; whereas, in reality, if mixed with alcohol in the proportion ordered for the tincture, it yielded a considerable deposit. The error of the Pharmacopœia consisted in an insufficient concentration, after the addition of the nitric acid, so that the nitric acid was not completely decomposed, and failed of course to change the protochloride completely into the sesquichloride. But, were the evaporation to be continued, a large quantity of basic chloride would be thrown down because the proportion of muriatic acid

directed in the formula was insufficient to sesquichloridize the whole of the protochloride. The formula, therefore, required revision in both these respects; and, in the present edition of the Pharmacopœia, it has been altered in both. The muriatic acid has been increased from ten to twelve fluidounces and the nitric from six to nine fluidrachms; and instead of simply evaporating the solution after the addition of nitric acid to a certain bulk, the directions now are to heat the mixture briskly until the occurrence of red fumes shows that the iron is sesquioxidized, while the muriatic acid added at the same time fulfils the purpose of sesquichloridizing the metal. The process now accomplishes its object, and the result corresponds with the tests given.

The strong solution of perchloride of iron, properly made, is of an orange colour and a strongly astringent, chalybeate taste. Water and alcohol unite with it in all proportions. When diluted with water, it gives a white precipitate with nitrate of silver, and a blue one with the ferrocyanide of potassium, but not with the ferridcyanide. The sp. gr. is 1·338. The Pharmacopœia gives as a test that "a fluidrachm of it diluted with two fluidounces of water gives, upon the addition of an excess of solution of ammonia, a reddish-brown precipitate, which, when well washed and incinerated, weighs 15·62 grains." *Br.* When this test is answered, the solution is about four times as strong in iron as the U. S. Tincture of the Chloride.*

From the experiments of M. Adrian it appears that sugar has the property, when mixed in certain proportions with solution of sesquichloride (perchloride) of iron, of converting it partly into protochloride. The alteration commences immediately on the addition of sugar, as shown by the deeper colour of the liquid; after some hours ferridcyanide of potassium will indicate the presence of a proto-salt; and, after 24 hours, the greater proportion of the sesqui-salt has undergone the change. (*Bost. Med. and Surg. Journ.*, March 12, 1868, p. 85; from *Revue Méd.*, Dec. 31, 1867.)

Medical Uses. This preparation was brought prominently into notice by M. Pravaz, a surgeon of Lyons, who found that a few drops of a strong solution, injected into a blood-vessel, produced coagulation of all the blood in the vessel for the extent of an inch or more. Its use as a styptic was the necessary result of this observation. In this capacity it has been used in the cure of varices, and has even been recommended as an injection in ordinary aneurisms. In arresting hemorrhages from cut surfaces or wounded vessels it has proved remarkably successful. It has also been found advantageous as an application to nasal polypi, erectile tumours or *nævi materni* in infants, in ulcers about the nails, and in various cutaneous affections. (See *Chloride of Iron.*) Attempts have been made to cure nævi materni by the injection of the solution into the erectile tumour; but this proceeding is hazardous; and a fatal result is recorded as having occurred in an infant a month old. Five drops of the solution, introduced into the centre of the tumour, were followed instantly by a sharp cry, a brief convulsion, and death. In a similar case, an examination after

* This solution, when kept, has a disposition to deposit the insoluble oxychloride of iron, and the resulting excess of muriatic acid is apt to render it injuriously irritating. To obviate this disadvantage, M. Burin du Buisson recommends the following mode of preparation. "Saturate as quickly as possible pure and colourless muriatic acid with [gelatinous] hydrated peroxide of iron; evaporate the solution to somewhat less than one-half over a gentle fire; and then continue the evaporation by means of the salt-bath, taking care to remove the aqueous vapours, which would cause the formation of muriatic acid, and a deposition of insoluble oxychloride. When the solution has attained the consistence of thick syrup (in which state it curdles on cooling, without, however, becoming a solid mass), cease evaporating, add an excess of the gelatinous hydrate diluted with a little water, agitate for a quarter of an hour, and afterwards allow the liquor to rest for several hours. Next add distilled water sufficient to bring the solution to the density of 30° Baumé, and allow it to stand for eight days in contact with an excess of the hydrate; after which filter, and again allow it to stand for two weeks." This strength of the solution is required for the cure of varices. For injection into aneurismal tumours, it is sufficient to employ a solution of 20° or even 15°. These degrees of Baumé are equivalent, 30° to 29·70 per cent. of the dry salt, 20° to 17·05 per cent., and 15° to 12·10 per cent. (See *Ferri Chloridum*, U. S., *page* 1126.)

death showed that the point of the instrument had entered a vein. (*Ann. de Thérap.*, 1867, p. 117.) It may be used internally, properly diluted, for the general purposes of the chalybeates, and especially as a substitute for the tincture of the chloride of iron, when the alcohol of that preparation may be objectionable. In the *Southern Journ. of Med. Sci.* (Nov. 1867), Dr. G.W. Lenoir states that he has tried this solution, with uniform success, in several cases of intermittent fever, in which he had failed with quinia. In only one case was there a recurrence of a paroxysm, and in this only once. He gave from 8 to 15 drops every 4 or 6 hours. (*Am. J. of Med. Sci.*, Jan. 1868, p. 284.) For ordinary purposes the dose would be from two to ten minims. In the Br. Pharmacopœia it is used in the preparation of the tincture of the chloride.

W.

LIQUOR FERRI SUBSULPHATIS. *U. S. Solution of Subsulphate of Iron. Solution of Persulphate of Iron. Monsel's Solution.*

"Take of Sulphate of Iron, in coarse powder, *twelve troyounces;* Sulphuric Acid *a troyounce and thirty grains;* Nitric Acid *a troyounce and three hundred grains;* Distilled Water *a sufficient quantity.* Mix the Acids with half a pint of Distilled Water, in a capacious porcelain capsule, and, having heated the mixture to the boiling point, add the Sulphate of Iron, one-fourth at a time, stirring after each addition until effervescence ceases. Then keep the solution in brisk ebullition until nitrous vapours are no longer perceptible, and the colour assumes a deep ruby tint. Lastly, when the liquid is nearly cold, add sufficient Distilled Water to make it measure twelve fluidounces." *U. S.*

This process is essentially that of Dr. Squibb, published in the *American Journal of Pharmacy* for January, 1860 (p. 33). The object is to obtain in solution *Monsel's Persulphate of Iron*, improperly so called, as it differs both in composition and properties from the salt of iron properly named persulphate. This consists of one eq. of sesquioxide of iron and three of sulphuric acid ($Fe_2O_3,3SO_3$), and is a neutral salt, while Monsel's persulphate consists of two eqs. of the sesquioxide and five of the acid ($2Fe_2O_3,5SO_3$), and, having one-half of an eq. less than is necessary for saturation, is properly a subsalt, as it is very appropriately designated in the U. S. Pharmacopœia. With this preliminary explanation, the process will be easily understood.

In its preparation the protoxide of iron of the protosulphate is sesquioxidized at the expense of the nitric acid; but the sulphuric acid, mixed with the nitric, is in quantity insufficient to the increased demand by the sesquioxide for neutralization. Thus, for each equivalent of the sesquioxide produced an additional eq. of acid would be necessary to constitute the neutral tersulphate of the sesquioxide, while the quantity added is only the half of one equivalent. The sesquioxide is therefore but partially saturated and a subsalt results, having the constitution above mentioned.

The solution of subsulphate of iron is of a syrupy consistence, a ruby-red colour, inodorous, of an extremely astringent but not acrid taste, without causticity, and of the sp. gr. 1·552. It mixes with water and alcohol in all proportions without decomposition. With ammonia it yields a copious reddish-brown precipitate of sesquioxide of iron. A little sulphuric acid decolorizes the liquid in a considerable degree, and an excess of the same acid converts it into a white, soft, pasty solid, resembling plaster of Paris when it has begun to solidify after mixture with water. This test, according to Dr. Squibb, is quite characteristic. (*Transact. King's Co. Med. Soc.*, in *N. Y. Journ. of Med.*, March, 1860, p. 173.)

By evaporation, upon a glass surface, with a moderate heat, the solution yields the subsulphate of the sesquioxide of iron in the form of thin transparent scales, of a light reddish-brown colour, deliquescent, and readily soluble in water.

Attention was first called to the special styptic virtues of sulphate of peroxide of iron by M. Monsel in 1852; but it was not till a later period that he discovered the peculiar salt which now goes by his name, and the solution of

which is the subject of the present article. It was in 1857 that he published a formula for the salt. (See *Journ. de Pharm.*, Sept. 1857, and Juillet, 1859.) The remedy soon became generally known in Europe; and a paper on the subject was published by Dr. Hutchinson in the *New York Journal of Medicine* for January, 1859; but it seems to have come into more general use in this country, through the published experience of Dr. H. H. Toland and others in the *Pacific Medical and Surgical Journal* of California.

In consequence of its deficiency of sulphuric acid, this salt is less irritant than the tersulphate of the sesquioxide, while it has at least equal if not greater astringency. It is therefore very efficacious as a styptic, and peculiarly adapted, through the power of coagulating the blood, to cases of hemorrhage from incised wounds, or surfaces in which it is specially desirable to avoid irritation. It is said also to have been found peculiarly efficacious in chancre. The solution may be applied by means of a small sponge or pencil of spun-glass to the bleeding surface or vessel. In cases of hæmoptysis, it has been used with advantage, by inhalation, in the form of spray, by means of the atomizer. For this purpose, however, it should be diluted with distilled water. It has also been used internally; and there is little doubt that it would prove efficacious as a styptic in hemorrhage from the stomach and bowels, and by injection into the rectum in bleeding from that part. It may be given in a dose of from five to fifteen grains. W.

LIQUOR FERRI TERSULPHATIS. *U. S.* Liquor Ferri Persulphatis. *Br. Solution of Tersulphate of Iron. Solution of Persulphate of Iron.*

"Take of Sulphate of Iron, in coarse powder, *twelve troyounces;* Sulphuric Acid *two troyounces and sixty grains;* Nitric Acid *a troyounce and three hundred and sixty grains;* Water *a sufficient quantity.* Mix the acids with half a pint of Water in a capacious porcelain capsule, and, having heated the mixture to the boiling point, add the Sulphate of Iron, one-fourth at a time, stirring after each addition until effervescence ceases. Then continue the heat until the solution acquires a reddish-brown colour, and is free from nitrous odour. Lastly, when the liquid is nearly cold, add sufficient Water to make it measure a pint and a half." *U. S.*

"Take of Sulphate of Iron *eight ounces* [avoirdupois]; Sulphuric Acid, Nitric Acid, of each, *six fluidrachms;* Distilled Water *twelve fluidounces*, or *a sufficiency.* Add the Sulphuric Acid to ten [fluid]ounces of the Water, and dissolve the Sulphate of Iron in the mixture, with the aid of heat. Mix the Nitric Acid with the remaining two [fluid]ounces of Water, and add the dilute acid to the solution of Sulphate of Iron. Concentrate the whole by boiling, until, upon the sudden disengagement of ruddy vapours, the liquid ceases to be black and acquires a red colour. A drop of the solution is now to be tested with red prussiate of potash [ferridcyanide of potassium], and if a blue precipitate forms, a few additional drops of Nitric Acid should be added, and the boiling renewed, in order that the whole of the sulphate may be converted into persulphate of iron. When the solution is cold, make the quantity eleven fluidounces by the addition, if necessary, of Distilled Water." *Br.*

The sulphate of iron used in these formulas is a sulphate of the protoxide of iron. The nitric acid in the process gives up enough of its oxygen to convert the protoxide entirely into sesquioxide, and the effervescence is owing to the escape of nitric oxide becoming red hyponitric acid by contact with the air. The conversion of protoxide into sesquioxide is incomplete until the effervescence ceases, and the colour, from black, as it was at first, has become reddish-brown. Indeed, in order to sesquioxidize the whole of the protoxide of the sulphate, it is necessary to continue the heat until nitrous odour ceases to be evolved; and thus, moreover, the entire absence of nitric or nitrous acid from the solution is ensured. But in consequence of the higher oxidation of the iron the sulphuric acid of the sulphate is insufficient to saturate it, and just in proportion to the additional oxygen. Enough sulphuric acid, therefore, is added to meet this demand,

that is, in such proportion as to give an eq. of the acid for each additional eq. of oxygen in the oxide. The process is completed by adding enough water to make a definite measure. The U. S. and British formulas are the same in principle; but in the latter, the additional precaution is taken, in order to ensure the complete change of protoxide into sesquioxide, of testing the liquid with ferridcyanide of potassium, which will produce a blue precipitate so long as any of the protoxide remains.

This solution, prepared according to the U. S. formula, is a perfectly clear and mobile liquid, in no degree viscid, of a reddish-brown colour, almost inodorous, of a sour, extremely astringent and somewhat acrid taste, and miscible in all proportions, without decomposition, with water and alcohol. The sp. gr. of the U.S. solution is 1·320; and a *fluidounce* of it yields, on the addition of ammonia in excess, a bulky precipitate, of a reddish-brown colour, and without blackish tinge, which, when washed, dried, and ignited, weighs 69 grains. The solution, diluted with water, gives a white precipitate with chloride of barium, showing that it contains a sulphate, and a blue precipitate with ferrocyanide of potassium, but none with the ferridcyanide, showing that the sulphate is that of sesquioxide of iron. It keeps well; and we have seen a specimen three or four years old, which retained all its properties unchanged, and had deposited nothing. The *British* solution is considerably stronger than ours, having the sp. gr. 1·441, and yielding from a *fluidrachm*, on precipitation by ammonia, a precipitate, which, when washed and incinerated, weighs 11·44 grains. It is described in the Br. Pharmacopœia as a dense solution of a dark-red colour. Prof. Procter has found that a preparation containing 120 grains of sesquioxide to the fluidounce is apt to deposit the anhydrous sulphate on standing.

This solution, though possessed of astringent properties rendering it useful as a styptic, is inferior remedially to that of the subsulphate of iron, which is less irritant, and certainly not less efficacious. The chief use of it is in making other ferruginous preparations, in which the sesquioxide of iron is wanted; and it should always be kept on hand, if for nothing else, for the quick preparation of the hydrated sesquioxide of iron, to be used as an antidote in cases of arsenical poisoning.

LIQUOR GUTTA-PERCHÆ. *U. S. Solution of Gutta-percha.*

"Take of Gutta-percha, in thin slices, *a troyounce and a half;* Purified Chloroform *seventeen troyounces;* Carbonate of Lead, in fine powder, *two troyounces.* To twelve troyounces of the Chloroform, contained in a bottle, add the Gutta-percha, and shake occasionally until it is dissolved. Then add the Carbonate of Lead, previously mixed with the remainder of the Chloroform, and, having several times shaken the whole together, at intervals of half an hour, set the mixture aside, and let it stand for ten days, or until the insoluble matter has subsided, and the solution become limpid, and either colourless or of a pale-straw colour. Lastly, decant the liquid, and keep it in a well-stopped bottle." *U. S.*

Difficulty is often experienced in obtaining a clear solution of gutta-percha in chloroform of the proper consistence for use, in consequence of its viscidity, and the strong affinity with which it holds on to the colouring matter. It cannot be clarified by filtration; and the carbonate of lead is therefore resorted to, which unites with the colouring matter, and, in consequence of its weight, gradually subsides, carrying undissolved substances along with it, and leaving a clear and colourless or nearly colourless solution behind. The use of carbonate of lead for the purpose was first suggested by Mr. Wm. Hodgson, jun., of Philadelphia. Something in the success of the process appears to depend on the quality of the gutta-percha used. Should the operator be unable to procure a clear solution

by acting in precise accordance with the formula, he would be justifiable in adding more chloroform, filtering if necessary, and evaporating by a very moderate heat to the due consistence. When the preparation becomes too viscid in consequence of the spontaneous evaporation of the menstruum on exposure, we have always found that the addition of a little chloroform, with agitation, restores it without difficulty to the due condition. The ordinary commercial chloroform may be used in the process, as the preparation is exclusively for external use. It should be kept in small glass vials, with accurately fitting glass stoppers, and not containing more than may be wanted at once, say a fluidounce.

We have nothing, on the whole, so convenient and effective as this preparation, as a protective to the surface, in slight cases of superficial inflammation and abrasion. By the rapidity with which the chloroform evaporates, a thin elastic nearly colourless film is left after its application, sufficient to prevent injurious influence from the air, wholly without irritating properties, not shrinking inconveniently, and, in consequence of its softness, not mechanically disturbing the part, as sometimes happens with collodion. A little of it applied by the end of the finger, or by means of a small brush, or a glass rod, over eruptive affections, abrasions or slight excoriations, inflammation from friction, chaps on the lips or hand, and slight superficial wounds that have ceased bleeding, will often enable the parts beneath to heal almost immediately, while, if unprotected, they might go on for an indefinite period, giving annoyance, and often increasing. Surfaces yet sound, that are liable to irritation and abrasion from contact, pressure, friction, and the application of acrid substances, may often be protected by a coating of this material. The agreeable odour of chloroform is another recommendation over other preparations, of a similar character, made with ether or benzole. We have so often experienced its advantages that we wish to press it upon the attention of the profession, which it has not yet received to the degree that it merits. One cause of this, perhaps, is the difficulty of obtaining it in the shops, a large proportion of which, either from the difficulties in its preparation, or want of demand, are insufficiently supplied. W.

LIQUOR HYDRARGYRI NITRATIS. *U.S.* Liquor Hydrargyri Nitratis Acidus. *Br. Solution of Nitrate of Mercury. Acid Solution of Nitrate of Mercury.*

"Take of Mercury *three troyounces;* Nitric Acid *five troyounces;* Distilled Water *six fluidrachms.* Dissolve the Mercury, with the aid of a gentle heat, in the Acid previously mixed with the Distilled Water. When reddish vapours cease to arise, evaporate the liquid to seven troyounces and a half, and keep it in a well-stopped bottle." *U. S.*

"Take of Mercury *four ounces* [avoirdupois]; Nitric Acid *five fluidounces* [Imperial measure]; Distilled Water *one fluidounce and a half.* Mix the Nitric Acid with the Water in a flask; and dissolve the Mercury in the mixture without the application of heat. Boil gently for fifteen minutes, cool, and preserve the solution in a stoppered bottle." *Br.*

In the process for making this new officinal of the U. S. Pharmacopœia, mercury is dissolved, with the assistance of heat, in an excess of nitric acid, and there is formed an acid binitrate of deutoxide of mercury, which is brought to a determinate bulk by evaporation. The nitric acid taken weighs five ounces. This proportion is sufficient not only to deutoxidize the mercury and generate a bisalt, but to furnish a large excess of acid. The solution is a dense, transparent, nearly colourless liquid, of a strongly acid taste, of the sp. gr. 2·165 as prepared by the U. S. process, and 2·246 by the British. Its distinguishing properties, as given in the U. S. and Br. Pharmacopœias, are that it is not precipitated by distilled water; gives when diluted a dull-yellow precipitate with potassa and a bright-red one soluble in an excess of the precipitant with iodide of potassium; does not produce a precipitate when dropped into muriatic acid diluted with twice its bulk of water; when dropped on a bright surface of copper instantly occasions a mercurial coating; and, finally, causes a crystal of

sulphate of iron dropped into it, as well as the liquid around the salt, to assume a dark colour. These tests show that the salt contained in it is a nitrate and not a sulphate, and that its base is deutoxide of mercury, without the presence of any protoxide of that metal. The rather loose direction, at the close of the British process, to boil for fifteen minutes, cannot but lead to somewhat uncertain results, unless care is taken by the operator to bring the sp. gr. of the solution to the point indicated in the description of the solution given in the Pharmacopœia.

Binitrate of deutoxide of mercury (the salt present in this preparation) is uncrystallizable, unless when exposed in a freezing mixture to a temperature of 5°, when it crystallizes with the formula $HgO_2,2NO_5+16HO$. (*H. S. Ditten.*) According to the new view of the equivalent of mercury, adopted in the Br. Pharmacopœia, the salt is a nitrate of protoxide of mercury, and is represented by the formula, independently of water of crystallization, HgO,NO_5.

Medical Properties. This preparation is frequently used in Europe, and has been employed to some extent in this country, as a caustic application to malignant ulcerations and cancerous affections. It has been used by Biett in lupus, by Bennett and others in ulceration of the neck of the uterus, and by Recamier in cancer. It is applied to the diseased surface by a camel's-hair brush, or preferably by a brush made of spun-glass. The parts touched immediately become white, the surrounding parts inflame, and in a few days a yellow scab is formed, which gradually falls off. Sometimes the application produces salivation. When it is desirable to avoid this result, the cauterized part should be washed with water immediately after the application of the caustic.

Acid nitrate of mercury is extensively used by Mr. Startin in the Hospital for Cutaneous Diseases, London.* He has employed it with advantage in acne, boils, carbuncle, lupus, sloughing ulcers, and other external affections. In acne, a very minute drop of the solution is placed, by means of a finely pointed glass brush, on the top of each indolent tubercle. The application, if carefully made, leaves no scar. In treating boils, a full-sized drop is applied to the apex of the furuncle. (*Med. Times and Gaz.*, Jan. 1855, p. 9.) B.

LIQUOR IODINII COMPOSITUS. *U. S.* Liquor Iodi. *Br. Compound Solution of Iodine. Solution of Iodine.*

"Take of Iodine *three hundred and sixty grains;* Iodide of Potassium *a troyounce and a half;* Distilled Water *a pint.* Dissolve the Iodine and Iodide of Potassium in the Distilled Water." *U. S.*

"Take of Iodine *twenty grains;* Iodide of Potassium *thirty grains;* Distilled Water *one fluidounce.* Dissolve." *Br.*

In this solution iodine is dissolved in water with the assistance of iodide of potassium. Iodine dissolves sparingly in water, but freely in a solution of that salt. In using iodide of potassium to render iodine more soluble in water, the iodide is generally taken in a quantity twice the weight of the iodine; and this is the proportion adopted in the U. S. formula. The preparation is a *concentrated* solution of iodine with iodide of potassium, and is intended to facilitate the administration of the combination in drops. A solution of the same kind, though weaker, was directed in the Edinburgh Pharmacopœia, but was omitted in the British. In the present Br. Pharmacopœia a solution is directed of the same strength in iodine as the U. S. solution, but considerably weaker in iodide of potassium; the former having only thirty grains in the fluidounce, the latter 45 grains; the difference in the fluidounce of the two Pharmacopœias being too small to enter into the calculation. The medicinal properties of the solution depend mainly on the free iodine contained in it, by which the dose must be regulated, and not by the iodide of potassium. According to Mr. Lloyd, of St. Bartholomew's Hospital, London, it acts differently from iodide of potassium, which, when given alone, does not produce the same effects. In a

* The acid nitrate, used by Mr. Startin, does not correspond, in the proportions employed, with the British preparation. It is made by dissolving two ounces of mercury in four ounces of nitric acid (sp. gr. 1·5).

case of constitutional syphilis under his care, the compound solution of iodine effected a rapid cure, after the iodide of potassium had been taken in large doses, for several months, without benefit. The dose is six drops, containing about a quarter of a grain of iodine, three times a day, given in four tablespoonfuls of sweetened water, and gradually increased. The dilution should always be large, in order to favour the absorption of the medicine, and to avoid any irritation of the stomach. For children the dose to begin with is two drops. B.

LIQUOR LITHIÆ EFFERVESCENS. *Br. Effervescing Solution of Lithia. Lithia Water.*

"Take of Carbonate of Lithia *ten grains;* Water *one pint* [Imperial measure]. Mix in a suitable apparatus, and pass into it as much pure washed carbonic acid, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles well closed, to prevent the escape of the compressed gas." *Br.*

This solution is clear and sparkling, has an agreeable acidulous taste, and, when evaporated, leaves a white solid residue of carbonate of lithia, in the proportion of five grains to half a pint (Imp. meas.), or about ten fluidounces. It is an appropriate method of administering carbonate of lithia; as this salt, compared with other alkaline carbonates, is sparingly soluble in pure water, and is readily dissolved by carbonic acid water. The quantity of carbonic acid is unnecessarily large; the pressure of five atmospheres, as directed in the U. S. formula for carbonic acid water, being sufficient for all practical purposes.

For the properties and uses of carbonate of lithia, see the article upon this salt in *Part* I. of the Dispensatory. The dose of the solution is from five to ten fluidounces. W.

LIQUOR MAGNESIÆ CARBONATIS. *Br. Solution of Carbonate of Magnesia. Fluid Magnesia.*

"Take of Sulphate of Magnesia *two ounces* [avoirdupois]; Carbonate of Soda *two ounces and a half* [avoird.]; Distilled Water *a sufficiency.* Dissolve the two salts separately, each, in half a pint [Imperial measure] of Water. Heat the Solution of Sulphate of Magnesia to the boiling point, then add to it the Solution of Carbonate of Soda, and boil them together till carbonic acid ceases to be evolved. Collect the precipitated carbonate of magnesia on a calico filter, and wash it with Distilled Water until what passes ceases to give a precipitate with chloride of barium. Mix the washed precipitate with a pint [Imp. meas.] of Distilled Water, and, putting them into a suitable apparatus, pass into it pure washed carbonic acid gas obtained by the action of sulphuric acid on chalk. Let the mixture remain in contact with excess of carbonic acid, retained there under pressure for about 24 hours, then filter the liquid to remove any undissolved carbonate of magnesia, and again pass carbonic acid gas into the filtered solution. Finally, keep the solution in a bottle securely closed, to prevent the escape of carbonic acid." *Br.*

The object of this process is to obtain a solution of carbonate of magnesia, by means of carbonic acid; the carbonate being insoluble in pure water. The first step is to prepare a freshly precipitated hydrated carbonate of magnesia, which is more readily dissolved than the carbonate which has been kept for some time. As the carbonate of magnesia of the Br. Pharmacopœia consists of three eqs. of the neutral carbonate and one of magnesia with 5 eqs. of water, it follows that, in its preparation from the two salts used in the process, a portion of carbonic acid escapes; and the boiling is directed to be continued until the escape of the gas ceases, so that the normal composition is ensured, and a longer heat, which might affect the constitution of the carbonate so as to diminish its solubility, avoided. The precipitate is thoroughly washed so as to remove every trace of sulphate of soda, which is indicated by the non-action of the test of chloride of barium. The next step is to dissolve the precipitated carbonate in water impregnated with carbonic acid gas; and, as the solution even thus favoured is slowly effected, the carbonate is directed to remain ex-

posed to the action of carbonic acid gas, under pressure, for 24 hours; and still the whole of the carbonate is not dissolved, and filtration is necessary. According to the Pharmacopœia, the "solution contains about 13 grains of carbonate of magnesia in a fluidounce." Were the results exactly in accordance with the proportion of sulphate of magnesia used, the quantity of carbonate dissolved would be 40 grains to the fluidounce.

This solution is but slightly effervescent, is clear, and is stated in the Br. Pharmacopœia to be free from bitterness. Nevertheless its taste is disagreeable, much more so than that of the undissolved carbonate. "A fluidounce of it, evaporated to dryness, yields a white solid residue, which, after being calcined, weighs not less than five grains." This residue is insoluble in water, and answers to the tests for magnesia.

A preparation, for which this was no doubt intended as an officinal substitute, has for many years been more or less used under the name of *Dinneford's Magnesia*, or *fluid magnesia* (see *page* 538); but this is of uncertain strength as found in the shops, and made according to no constant formula. Hence a deficiency which has existed in practical pharmacy has been supplied by this formula.* Our own experience with it, however, has not been so favourable as to induce us to prefer it to the undissolved carbonate, if prepared by rubbing this up well with a little ginger syrup, and then mixing it with the ordinary carbonic acid water of the shops. In this form the medicine is almost tasteless so far as the magnesia is concerned, is easily administered, and sits well upon the stomach.

The dose of the officinal solution, as an antacid laxative, is one or two fluidounces. W.

LIQUOR MAGNESIÆ CITRATIS. *U. S.* *Solution of Citrate of Magnesia.*

"Take of Magnesia *one hundred and twenty grains;* Citric Acid *four hundred and fifty grains;* Syrup of Citric Acid *two fluidounces;* Bicarbonate of Potassa *forty grains;* Water *a sufficient quantity.* Dissolve the Citric Acid in four fluidounces of Water, and, having added the Magnesia, stir until it is dissolved. Filter the solution into a strong twelve-ounce bottle containing the Syrup of Citric Acid. Then add the Bicarbonate of Potassa, and sufficient Water to nearly fill the bottle, which must be closed with a cork secured with twine. Lastly, shake the mixture occasionally until the Bicarbonate is dissolved." *U. S.*

This is a revised formula for solution of citrate of magnesia, which first appeared in the second edition of the U. S. Pharmacopœia of 1850. The original formula was soon found to have several defects. It called for the use of carbonate of magnesia, which often contains gritty impurities. Four-fifths of the carbonate was dissolved in the citric acid, and the solution filtered into a bottle containing the syrup of citric acid; and then the reserved fifth, mixed with water, was added to the acid citrate, and the bottle tightly corked. The addition of the reserved carbonate was intended to impregnate the preparation with carbonic acid by its solution in the excess of citric acid. To effect the solution of this reserved carbonate required at least half an hour. But the chief objection to the formula, as originally framed, was that the citrate of magnesia, when the solution was kept for some days, underwent a molecular change, resulting in the formation of a white granular precipitate, which rendered the solution unfit for medical use. This precipitate was found by Prof. Procter to consist of one eq. of citric acid, three of magnesia, and fourteen of water. In the revised formula, now adopted, magnesia, which is generally purer than the carbonate, is substituted for it; and the impregnation of the solution with carbonic acid is effected by adding, just before the closing of the bottle, a small quantity of bicarbonate of potassa in *crystals*, which dissolve immediately, instead of consuming half

* Messrs. Dinneford and Co. prepare this solution, upon a large scale, of the officinal strength. For some account of their method of proceeding, see the *London Med. Times and Gaz.* (April, 1868, p. 383.)—*Note to the thirteenth edition.*

an hour. The use of bicarbonate of potassa, it is true, introduces citrate of potassa, but in too small a proportion to be of any consequence.

Properties, &c. This officinal solution is founded on a preparation proposed by M. Rogé Delabarre, and improved by M. Rabourdin, of Paris. It is an aqueous solution of citrate of magnesia, containing an excess of citric acid, impregnated with carbonic acid, and sweetened with syrup. When properly prepared, it is a clear liquid, having an agreeable taste like that of lemonade. Overlooking the excess of acid which it contains, the salt present is that tribasic citrate, in which the three eqs. of basic water in the crystallized acid are replaced by three eqs. of magnesia. Accordingly it consists of one eq. of citric acid and three of magnesia. In the twelfth edition of the Dispensatory it is stated that, in the revised formula, this salt does not precipitate by keeping, as in the superseded one, probably because the solution contains a greater excess of acid. This statement seems to have been premature; as Prof. Maisch informs us that he had utterly failed to produce a stable preparation by the U. S. formula, but had succeeded by reducing the magnesia from 120 to 100 grains. The professor thinks that the proportion of syrup is too great, and he is perhaps right; as one fluidounce to the bottle of solution would probably be sufficient. It is advisable in preparing the solution to introduce the magnesia by small portions; as if too hastily added it disposes to the formation of the neutral citrate, which cannot afterwards be dissolved. (*Am. Journ. of Pharm.*, Jan. 1867, p. 1.)

Dorvault makes a solid citrate of magnesia which is perfectly and readily soluble, by melting on a sand-bath 100 parts of crystallized citric acid in its water of crystallization, and thoroughly incorporating with it 29 parts of calcined magnesia. A pasty mixture is formed, which soon hardens, and may be pulverized for use. Citrate of magnesia, thus prepared, is soluble in twice its weight of water. When in saturated solution it soon precipitates as a nearly insoluble hydrate; but with eight or ten times its weight of water, it forms a permanent solution. See the report on the solid citrate, made by E. Parrish and A. Smith to the Philadelphia College of Pharmacy (*Am. Journ. of Pharm.*, April, 1852, p. 113). See also M. E. Robiquet's paper on lemonades of citrate of magnesia (*Journ. de Pharm.*, Avril, 1852, p. 295), and his formula for preparing a soluble citrate of magnesia. (*Am. Journ. of Pharmacy* for July, 1855.) M. Simonin finds that an insoluble citrate of magnesia may be restored to solubility in boiling water, by being thoroughly rubbed up with water so as to form a paste. The necessary trituration is abridged, if a little citric acid be added. (*Ann. de Thérap.*, 1857, p. 124.) Mr. Charles Ellis, of this city, prepares a soluble citrate of magnesia with sugar, citric acid, bicarbonate of soda, and oil of lemons, in the form of a powder, which effervesces when mixed with water. For the details of the formula, the reader is referred to his paper in the *Am. Journ. of Pharmacy* for July, 1854.*

* *Solid Citrate of Magnesia.* This salt as heretofore prepared, though soluble at first, is apt to become more or less insoluble, when kept, in consequence of molecular change. The following process, by M. de Letter, of Brussels, yields a salt which is said to retain its solubility indefinitely. "Take of Citric Acid 20 parts, and of Carbonate of Magnesia 12 parts. Powder the acid finely, and mix it intimately with the carbonate, also in fine powder. Allow the mixture to stand, at the ordinary temperature, for four or five days, or until it ceases to manifest reaction when a little is thrown into water. During this time the powder slowly swells up, and gradually assumes the appearance of a spongy mass. Dry this at 86° F., pulverize it, and keep the powder in closely stopped vials." According to M. de Letter, water, in a certain quantity, favours the formation of an insoluble hydrate; and hence the success of his process, in which no other water is present than that which is solidified in the dry materials. (See *Am. Journ. of Pharm.*, July, 1863, p. 312.)

M. Hager has been unable to prepare a soluble salt by the process of M. de Letter. He considers citrate of magnesia as presenting itself in three forms: 1. *crystallizable*, soluble in from 80 to 90 parts of water, with the formula $3MgO,Ci + 14HO$; 2. *amorphous*, soluble in two parts of water; and 3. *metamorphous*, soluble in 8 or 10 parts of water, with a strong tendency to crystallize. It is the crystalline variety, presenting the form of microscopic needles, that occasions the difficulty; and its production should be avoided. M. Hager proceeds in the following manner. Rub 40 parts of citric acid and 25 of carbonate of magnesia, both in powder, with sufficient alcohol of ·833 to make a thick mixture; and, having

Medical Properties. This solution is a cooling cathartic, and operates mildly It has come into extensive use in the United States, on account of the facility with which it may be taken, and its acceptability to the stomach. The dose as a full purge is the whole quantity directed in the formula, or twelve fluidounces; as a laxative, half that quantity or less. B.

LIQUOR MORPHIÆ ACETATIS. *Br.* *Solution of Acetate of Morphia.*

"Take of Acetate of Morphia *four grains;* Diluted Acetic Acid *eight minims;* Rectified Spirit *two fluidrachms* [Imperial measure]; Distilled Water *six fluidrachms.* Mix the Acid, the Spirit, and the Water, and dissolve the Acetate of Morphia in the mixture." *Br.*

Acetate of morphia often contains a little uncombined morphia, in consequence of the escape of a portion of the acid during its evaporation, and especially when this is pushed to dryness. Hence the addition of the diluted acetic acid, which at the same time neutralizes the alkaloid in excess, and enables the solution to be completely effected. The spirit is added for its preservative effect. The dose is from 15 to 30 minims, equivalent to from one-eighth to one-quarter of a grain of the acetate, and about as many drops of laudanum as minims of the solution. The preparation is only one-half the strength of the old London preparation of the same name. W.

LIQUOR MORPHIÆ HYDROCHLORATIS. *Br.* LIQUOR MORPHIÆ MURIATIS. *Dub.* *Solution of Hydrochlorate of Morphia. Solution of Muriate of Morphia.*

"Take of Hydrochlorate of Morphia *four grains;* Dilute Hydrochloric Acid *eight minims;* Rectified Spirit *two fluidrachms;* Distilled Water *six fluidrachms.* Mix the Hydrochloric Acid, the Spirit, and the Water, and dissolve the Hydrochlorate of Morphia in the Mixture." *Br.*

The use of the alcohol is to prevent spontaneous decomposition, that of the acid probably to assist in the solution of the salt. It is unfortunate that, in the solutions of the salts of morphia, the same degree of strength should not have been directed by the U. S. and Br. Pharmacopœias. As they now are, the medical practitioner and apothecary must be on their guard to avoid serious results. The strength of this solution is four times that of our officinal solution of sulphate of morphia, one fluidounce of the former containing four grains, of the latter only one grain of their respective salts. The full dose of the British solution for an adult is from fifteen to thirty minims or drops, containing from an eighth to a quarter of a grain of the hydrochlorate, and about equivalent to as many drops of laudanum. W.

LIQUOR MORPHIÆ SULPHATIS. *U.S.* *Solution of Sulphate of Morphia.*

"Take of Sulphate of Morphia *eight grains;* Distilled Water *half a pint.* Dissolve the Sulphate of Morphia in the Distilled Water." *U. S.*

Sulphate of morphia, as found in the shops, is not always entirely soluble in water. This sometimes, perhaps, arises from adulterations; but more frequently, in all probability, from the mode of making the sulphate. As this salt was formerly prepared, the quantity of water employed for the suspension of the morphia was sometimes insufficient to hold the resulting sulphate in solution; and the consequence was that, upon the addition of sulphuric acid, the crystallization of the sulphate took place before the whole of the morphia was saturated by the acid. A portion of uncombined morphia was therefore necessarily mixed with the salt. Under such circumstances, the addition of a little sulphuric acid usually

allowed this to stand for several days, at a medium temperature, dry it at a heat of 113° F. The product is the amorphous salt, soluble in 2·5 parts of water, in half an hour at 60°, immediately at 86°. Its solution, whether made with hot or cold water, retains its clearness after long standing. The salt is neutral, and contains about 13 eqs. of water. To succeed certainly it is necessary that the carbonate of magnesia be free from dust and impurities. (*Ibid.*, Jan. 1864, p. 19.)—*Note to the twelfth edition.*

remedied the defect, and rendered the whole soluble. Pure sulphate of morphia is readily and entirely soluble in water.

This solution is very convenient, by enabling the physician to prescribe a minute dose, which, in consequence of the great energy of the preparations of morphia, is often necessary. It has the advantage that it may be kept for a very considerable length of time unchanged. The full dose for an adult is from one to two fluidrachms, containing from an eighth to a quarter of a grain of the sulphate.

Unfortunately, in some parts of the Union, the formula of Magendie for this solution, containing 16 grains in a fluidounce, is habitually employed under the name of solution of sulphate of morphia. This is the proper name of the officinal solution, which is much weaker; and the most dangerous results may ensue from the confusion. Magendie's solution should never be prescribed or sold, unless under some special designation. W.

LIQUOR PLUMBI SUBACETATIS. *U. S.*, *Br.* *Solution of Subacetate of Lead.*

"Take of Acetate of Lead *sixteen troyounces;* Oxide of Lead [Litharge], in fine powder, *nine troyounces and a half;* Distilled Water *a sufficient quantity.* Boil the Acetate and Oxide with four pints of Distilled Water, in a glass or porcelain vessel, for half an hour, occasionally adding Distilled Water to preserve the measure, and filter through paper. Lastly, keep the liquid in a well-stopped bottle." *U. S.* The sp. gr. of this solution is 1·267.

"Take of Acetate of Lead *five ounces* [avoirdupois]; Oxide of Lead, in powder, *three ounces and a half* [avoird.]; Distilled Water *one pint* [Imperial measure], or *a sufficiency.* Boil the Acetate of Lead and the Oxide of Lead in the Water for half an hour, constantly stirring; then filter, and, when the liquid is cold, add to it more Distilled Water, until the product measures twenty fluidounces. Keep the clear solution in stoppered bottles." *Br.* The sp. gr. of the solution is 1·260.

Crystallized acetate of lead consists of one equivalent of acetic acid 51, one of protoxide of lead 111·6, and three of water 27 = 189·6. Litharge, as usually found in the shops, is an impure protoxide of lead. When the solution of the former is boiled with the latter, a large quantity of the protoxide is dissolved, and a subacetate of lead is formed which remains in solution. The precise composition of the subacetate varies with the proportion of acetate of lead and of litharge employed. When the quantity of the latter exceeds that of the former by one-half or more, the acetic acid of the acetate unites, according to the highest chemical authorities, with two additional equivalents of protoxide, forming a trisacetate; when the two substances are mixed in proportions corresponding with their equivalent numbers, that is, in the proportion of 189·6 of salt to 111·6 of oxide, or 10 to 6 nearly, only one additional equivalent of protoxide unites with the acid, and a diacetate of lead is produced. In the officinal process, the proportions appear to have been arranged in reference to this result. In executing the process, the litharge should be employed in very fine powder, and, according to Thenard, should be previously calcined in order to decompose the carbonate of lead, which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate.

In former editions of the London and Dublin Pharmacopœias, a different process was directed, consisting in boiling litharge with distilled vinegar, the former being in much larger proportion than necessary to form the neutral acetate. A diacetate was thus produced; but, as the vinegar was of uncertain strength, there was necessarily more or less inequality of strength in the preparation. This process, therefore, has been abandoned. The solution prepared from litharge and distilled vinegar has a pale greenish-straw colour, owing to impurities in the vinegar. Made with common vinegar it is brown.

Properties. The solution of subacetate of lead of the Pharmacopœias is colourless, and of a sweetish, astringent taste. When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Dr. Barker,

are flat, rhomboidal prisms, with dihedral summits. It has an alkaline reaction, tinging the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which it is decomposed. Carbonic acid throws down a white precipitate of carbonate of lead; and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbonic acid from the atmosphere. It affords precipitates also with the alkalies, alkaline earths, and their carbonates, with sulphuric and muriatic acids free or combined, with hydrosulphuric acid and the hydrosulphates, with the soluble iodides and chlorides, and, according to Thenard, with solutions of all the neutral salts. Solutions of gum, tannin, most vegetable colouring principles, and many animal substances, particularly albumen, produce with it precipitates consisting of the substance added and oxide of lead. It should be kept in well-stopped bottles. It is known to contain a salt of acetic acid by emitting an acetous smell when treated with sulphuric acid; and a salt of lead, by yielding a white precipitate with an alkaline carbonate, a yellow one with iodide of potassium, and a black one with hydrosulphuric acid. It is distinguished from the solution of acetate of lead by being precipitated by gum arabic. Six fluidrachms (413·8 grains) of the Br. solution require for perfect precipitation 810 grain-measures of the *volumetric solution of oxalic acid. Br.*

Medical Properties and Uses. This solution is astringent and sedative, but is employed only as an external application. It is highly useful in inflammation arising from sprains, bruises, burns, blisters, &c., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. From four fluidrachms to a fluidounce, added to a pint of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker; as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action. The solution has the common name of *Goulard's extract*, derived from a surgeon of Montpellier by whom it was introduced into general notice, though previously employed.

Off. Prep. Ceratum Plumbi Subacetatis, *U. S.;* Liquor Plumbi Subacetatis Dilutus; Unguentum Plumbi Subacetatis Compositum, *Br.* W.

LIQUOR PLUMBI SUBACETATIS DILUTUS. *U.S., Br. Diluted Solution of Subacetate of Lead. Lead-water.*

"Take of Solution of Subacetate of Lead *three fluidrachms;* Distilled Water *a pint.* Mix them." *U. S.*

"Take of Solution of Subacetate of Lead, Rectified Spirit, of each, *two fluidrachms;* Distilled Water *nineteen fluidounces and a half.* Mix, and filter through paper. Keep the clear solution in a stoppered bottle." *Br.*

This preparation is convenient; as, in consequence of the subsidence of the carbonate of lead usually formed on the dilution of the strong solution, it enables the apothecary to furnish clear lead-water when it is called for. In our comments on the U. S. process of 1850, it was stated that the strength of our officinal preparation, though double what it formerly was, might be still further increased with propriety. In the present edition of the U. S. Pharmacopœia the proportion has been increased from two to three fluidrachms to the pint. The Br. preparation, though stronger than the old one of the London College, is still feeble. The old French Codex directed two drachms of the strong solution to a pound of distilled water, and an ounce of alcohol of 22° Baumé, and thus formed the *vegeto-mineral water* of Goulard. The minute proportion of proof spirit in the British solution can have little effect. The preparation should be as much as possible excluded from the air. W.

LIQUOR POTASSÆ. *U.S., Br. Solution of Potassa.*

"Take of Bicarbonate of Potassa *fifteen troyounces;* Lime *nine troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Bicarbonate in four pints of

Distilled Water, and heat the solution until effervescence ceases. Then add Distilled Water to make up the loss by evaporation, and heat the solution to the boiling point. Mix the Lime with four pints of Distilled Water, and, having heated the mixture to the boiling point, add it to the alkaline solution, and boil for ten minutes. Then transfer the whole to a muslin strainer, and, when the liquid portion has passed, add sufficient Distilled Water, through the strainer, to make the strained liquid measure seven pints. Lastly, keep the liquid in well-stopped bottles of green glass. Solution of potassa, thus prepared, has the sp. gr. 1·065, and contains 5·8 per cent. of hydrate of potassa.

"Solution of Potassa may also be prepared in the following manner.

"Take of Potassa *a troyounce;* Distilled Water *a pint.* Dissolve the Potassa in the Distilled Water, and allow the solution to stand until the sediment subsides. Then pour off the clear liquid, and keep it in a well-stopped bottle of green glass." *U. S.*

"Take of Carbonate of Potash *one pound* [avoirdupois]; Slaked Lime *twelve ounces* [avoird.]; Distilled Water *one gallon* [Imperial measure]. Dissolve the Carbonate of Potash in the Water; and, having heated the solution to the boiling point, in a clean iron vessel, gradually mix with it the Slaked Lime; and continue the ebullition for ten minutes with constant stirring. Then remove the vessel from the fire; and, when by the subsidence of the insoluble matter the supernatant liquor has become perfectly clear, transfer it by means of a siphon to a green-glass bottle furnished with an air-tight stopper, and add distilled water, if necessary, to make it correspond with the tests of sp. gr. and neutralising power. The sp. gr. is 1·058." *Br.*

The object of the first U. S. and of the British process is to separate carbonic acid from the carbonate or bicarbonate of potassa, so as to obtain the alkali in a caustic state. This separation of the carbonic acid is effected by hydrate of lime; and the chemical changes which take place are most intelligibly explained by supposing the occurrence of a double decomposition. The lime of the hydrate of lime, by its superior affinity, combines with the carbonic acid, and precipitates as carbonate of lime; while the water of the hydrate of lime unites with the potassa and remains in solution as hydrate of potassa. The proportion indicated by theory for this decomposition would be 69·2 of the dry carbonate to 28 of lime, or one equivalent of each; but in practice it is found necessary to use an excess of lime. The bicarbonate is preferred in the U. S. process, as affording a purer product, being itself free from the contaminations usually found in the carbonate; and the application of heat to the solution of the bicarbonate is to drive off a portion of the carbonic acid and thus bring the salt to the state of a carbonate. The proportion of water employed has a decided influence on the result. If the water be deficient in quantity, the decomposing power of the lime, on account of its sparing solubility, will be lessened; and more of it will be required to complete the decomposition of the carbonate than if the solutions were more dilute. Straining must not be used; as it causes a prolonged contact with the air, and risk of the absorption of carbonic acid, and is apt, moreover, to introduce organic matter from the strainer into the solution. The direction to keep the solution in green glass bottles is judicious; as white flint glass is slightly acted on, and contaminates the solution with lead.*

As the solution of potassa is made by the manufacturing chemist in considerable quantities, the following details, taken from Berzelius, of the best

* For remarks by Prof. Redwood, of London, in relation to the preparation of this Solution, and for a new process for which various advantages are claimed, the reader is referred to the *London Pharmaceutical Journal* for March, 1861, p. 450. The following are the outlines of the process. Into a stoppered bottle of green glass is introduced a mixture of ℥viiss of slaked lime and three Imperial pints of distilled water; and to this mixture is added, in small quantities at a time, a solution of ℥viiss of carbonate of potassa in one Imperial pint of distilled water, the bottle being shaken for some minutes after each addition. After the last addition, continue the shaking until a portion of the filtered liquid no longer gives out carbonic acid, upon adding an excess of muriatic acid through calico. (*Note to the twelfth edition.*)

mode of conducting the process, may not be without their use. Dissolve one part of carbonate of potassa in from seven to twelve parts of water in a bright iron vessel, and decant the solution after it has become clear by standing. Boil the solution in an iron vessel, and, while it is boiling, add at intervals small quantities of slaked lime, reduced to a thin paste with water; allowing the solution to boil a few minutes after each addition. One and a half parts of pure lime will be more than sufficient to decompose one part of the carbonate. When about half the hydrate of lime has been added, take out about a teaspoonful of the boiling solution, and, after dilution and filtration through paper, test it by adding it to some nitric acid, or by mixing it with an equal bulk of lime-water. If the solution has not been completely freed from carbonic acid, the first reagent will cause an effervescence, and the second a milky appearance; in either of which events the addition of the lime must be continued as before, until the above-mentioned tests give negative indications. In conducting the process, several advantages are gained by keeping the solution constantly boiling. One is that the carbonate of lime formed is in this way rendered granular and heavy, and more disposed to subside; another, that it prevents the precipitated carbonate from coalescing into a mass at the bottom of the vessel, an occurrence which causes the ebullition, when subsequently renewed, to take place imperfectly and by jerks; and a third, that any silica present is precipitated in combination with lime and potassa. The process here described is essentially the same with those introduced into the last editions of the Edinburgh and Dublin Pharmacopœias.

According to Prof. Wöhler, solution of pure hydrate of potassa for analytic purposes may be conveniently obtained by exposing for half an hour to a moderate red heat, in a copper crucible, one part of pure nitre, and two or three parts of copper cut into small pieces. The resulting mass, consisting of hydrate of potassa and black oxide of copper, is treated with water, and the solution poured into a narrow cylindrical vessel, where it is left until it gets perfectly clear by the deposition of the oxide of copper. It is then drawn off, and kept in well-stopped bottles. (*Chem. Gaz.*, Nov. 15, 1853, p. 429.) Graf and Riegel assert that hydrate of potassa, thus obtained, contains nitrate and nitrite of potassa; but Dr. A. Geuther found it perfectly pure, when the process was properly conducted. (*Chem. Gaz.*, June 1, 1856.) A pure hydrate may also be obtained by the process of Dr. Mohr, of Coblentz, which consists in precipitating solution of sulphate of potassa with caustic baryta, obtained from the nitrate. Thus procured, the alkali is entirely free from chlorine, silica, and sulphuric acid. (*Pharm. Journ.*, xvi. 310.)

Properties, &c. Solution of potassa is a limpid, colourless liquid, without smell, of an acrid caustic taste, and alkaline reaction. It acts rapidly on animal and vegetable substances, and, when rubbed between the fingers, produces a soapy feel, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and forms soap with oily and fatty bodies. The Br. solution is never pure, but contains either undecomposed carbonate, or free lime, in addition to minute portions of sulphate of potassa, chloride of potassium, silica, and alumina; impurities usually present in the carbonate of potassa used in their preparation. The U. S. solution, being obtained from the bicarbonate of potassa, is purer. Undecomposed carbonate may be detected in the manner explained in a preceding paragraph, and free lime by the production of a milky appearance on the addition of a few drops of carbonate of potassa, which precipitates the lime as a carbonate. When saturated with nitric acid, the solution should give little or no precipitate with carbonate of soda, chloride of barium, or nitrate of silver. The presence of lead is detected by a black precipitate produced by hydrosulphuret of ammonia. When solution of potassa is used as a test for diabetic urine, it should be free from lead, the presence of which renders the indications of the test ambiguous. (See *Wood's Practice of Med.*, 4th ed., ii. 586.) With bichloride of platinum it produces a yellow precipitate, showing that the alkali present is potassa. It is incompatible with acids, acidulous salts, and all metallic and earthy preparations held in solution

by an acid; also with all ammoniacal salts, and with calomel, and corrosive sublimate. The two officinal solutions of potassa vary in strength; the U. S. solution having the sp. gr. 1·065 and the Br. 1·058. These solutions are very dilute; that of the U. S. Pharmacopœia, which is the strongest, containing only 5·8 per cent. of hydrate of potassa. There must, however, be some mistake either in the U. S. or British statement; for, while the greater sp. gr. given by the former indicates greater strength, the percentage of the hydrate of potassa as stated in the Br. Pharmacopœia is 5·84, or somewhat greater than the American. One fluidounce of the British solution (462·9 grains) requires for neutralization 482 grain-measures of the *volumetric solution of oxalic acid. Br.* On account of its strong attraction for carbonic acid, solution of potassa should be carefully preserved from contact with the air. In consideration of the change to which it is liable by keeping, it may sometimes be advantageously prepared extemporaneously, according to the second U. S. process, by dissolving the hydrate in water. B.

Medical Properties and Uses. Solution of potassa is antacid, diuretic, and antilithic. It has been much employed in calculous complaints, under the impression that it has the property of dissolving urinary concretions in the kidneys and bladder; but experience has proved that the stone once formed cannot be removed by remedies internally administered; and the most that the alkaline medicines can effect, is to correct that disposition to the superabundant secretion of uric acid, or the insoluble urates, upon which gravel and stone often depend. For this purpose, however, the carbonated alkalies are preferable to caustic potassa, as they are less apt to irritate the stomach, and to produce injurious effects when long continued. It has been proposed to dissolve calculi by injecting immediately into the bladder the solution of potassa in a tepid state, and so much diluted that it can be held in the mouth; but this mode of employing it has not been found to answer in practice. This solution has also been highly recommended in lepra, psoriasis, and other cutaneous affections; and is said to have proved peculiarly useful in scrofula; but in all these cases it probably acts simply by its antacid property, and is not superior to the carbonate of potassa or of soda. Externally it has been used, in a diluted state, as a stimulant lotion in rachitis and arthritic swellings, and, concentrated, as an escharotic in the bite of rabid or venomous animals. The dose is from ten to thirty minims, repeated two or three times a day, and gradually increased in cutaneous affections to one or two fluidrachms; but the remedy should not be too long continued, as it is apt to debilitate the stomach. It may be given in sweetened water or some mucilaginous fluid. Veal broth and table beer have been recommended as vehicles; but the fat usually present in the former would be apt to convert the alkali into soap, and the acid in the latter would neutralize it. In dyspeptic cases it may be associated with the simple bitters. In excessive doses it irritates, inflames, or corrodes the stomach. The antidotes are oils and milder acids, such as vinegar and lemon-juice, which operate by neutralizing the alkali.

LIQUOR POTASSÆ ARSENITIS. *U.S.* Liquor Arsenicalis. *Br. Solution of Arsenite of Potassa. Arsenical Solution. Fowler's Solution.*

"Take of Arsenious Acid, in small pieces, Bicarbonate of Potassa, each, *sixty-four grains;* Compound Spirit of Lavender *half a fluidounce;* Distilled Water *a sufficient quantity.* Boil the Arsenious Acid and Bicarbonate of Potassa, in a glass vessel, with twelve fluidounces of Distilled Water, until the Acid is entirely dissolved. To the solution, when cold, add the Compound Spirit of Lavender, and afterwards sufficient Distilled Water to make it measure a pint." *U. S.*

"Take of Arsenious Acid, in powder, Carbonate of Potash, of each, *eighty*

grains; Compound Tincture of Lavender *five fluidrachms* [Imperial measure]; Distilled Water *a sufficiency.* Place the Arsenious Acid and Carbonate of Potash in a flask with ten [fluid]ounces of the Water, and apply heat until a clear solution is obtained. Allow this to cool. Then add the Compound Tincture of Lavender, and as much Distilled Water as will make the bulk one pint [Imp. meas.]." *Br.* The sp. gr. of this solution is 1·009.

This preparation originated with the late Dr. Fowler, of Stafford, England, and was intended as a substitute for the celebrated remedy known under the name of "the *tasteless ague drop.*" It is an arsenite of potassa dissolved in water, and is formed by the combination of the arsenious acid with the potassa of the bicarbonate or carbonate, the carbonic acid being evolved. In the present U.S. process, the bicarbonate has been substituted for the carbonate, because more readily obtained pure. Its eq. corresponds so nearly with that of arsenious acid that, practically, the equal quantities directed will serve the purposes of the formula. According to M. H. Buignet, ebullition disengages the carbonic acid slowly; so that, after four hours' boiling, the solution still retains about one-sixth of this acid. (*Journ. de Pharm.*, Dec. 1856, p. 440.) The name by which the preparation is designated in the U. S. Pharmacopœia is the most correct. It has, however, been denied that the carbonate of potassa is decomposed by the arsenious acid, which is supposed to be merely held by it in solution; and, in this view of the nature of the preparation, the British name of Arsenical Solution would be appropriate. The spirit of lavender is added to give it taste, and prevent its being mistaken for water. The U. S. preparation is of about the same strength as the British; for, although one-fourth more acid and alkali is taken in the latter formula, yet the Imperial pint is nearly one-fourth larger than the wine pint.

In making this preparation, care should be taken that the arsenious acid is pure. This object is best secured by using the acid in small pieces instead of in powder. Sulphate of lime is a common impurity in the powdered acid, and if present will remain undissolved, and cause the solution to be weaker than it should be. Another insoluble impurity in the powdered acid is arsenite of lime, which is sometimes present to the amount of 25 per cent. (*Buignet.*) Hence, if the arsenious acid does not entirely dissolve, the solution must be rejected.

Properties. Solution of arsenite of potassa is a transparent liquid, having the colour, taste, and smell of the spirit of lavender. It has a strong alkaline reaction. It is decomposed by the usual reagents for arsenic, such as nitrate of silver, the salts of copper, lime-water, and sulphuretted hydrogen; and is incompatible with infusions and decoctions of cinchona. Before sulphuretted hydrogen will act, the solution must be acidulated with some acid, as the muriatic or acetic. If very long kept in flint glass, it is apt to suffer partial decomposition, exhaling a garlicky odour, and giving the inner surface of the bottle a metallic lustre, owing to the lead of the glass being revived. (Canavan, *N. Y. Journ. of Pharm.*, i. 131.) According to Dr. R. Fresenius, solutions of alkaline arsenites, by keeping, absorb oxygen from the air, and are in part converted into arseniates. Hence the propriety of keeping this solution in small bottles quite filled. Mohr states that the alkaline reaction of the officinal solution delays the change.

Medical Properties and Uses. This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arsenious Acid.* Its liquid form makes it convenient for exhibition and gradual increase; and it is the preparation generally resorted to when arsenic is given internally. It has been much employed in intermittent fever. The late Prof. Thomas D. Mitchell, of Jefferson Medical College, gave the result of his experience, as to its efficacy and safety in this disease, when exhibited in the large dose of fifteen or twenty drops three times a day. It is a valuable resource in the intermittents of children, who are with difficulty induced to swallow bark or even sulphate of quinia. The late Dr. Dewees related the case of a child only six weeks old, affected with a severe tertian, in which this solution was given with success. A fluidrachm was diluted with twelve fluidrachms of water; and of this six drops were given every four hours.

Fowler's solution is useful in many diseases. It has been employed with great success in lepra and other inveterate cutaneous affections. The late Dr. S. Calhoun published an account of five cases of nodes successfully treated by it; and Dr. Baer, of Baltimore, and the late Dr. Eberle afterwards gave it a trial in this affection, and obtained satisfactory results. Several cases of chorea, cured by it, are reported by Mr. Martin, Mr. Slater, and Dr. Gregory, in the *Medico-chirurgical Transactions* of London. Two interesting cures of periodical headache, performed by the solution, were related by the late Dr. Otto, of Philadelphia, in the *North American Med. and Surg. Journal* (vols. iv. and v.). Mr. H. Hunt found it useful in menorrhagia, but prefers arsenious acid, as less apt to produce unpleasant effects. Dr. Fuller, of London, praises its effects in rheumatic gout, attended with turbid urine, in the dose of from eight to fifteen minims, conjoined with solution of potassa, or acetate of potassa. For an account of the successful use of Fowler's solution in five cases of snake-bite, see *page* 26. A diluted solution, in the proportion of a fluidrachm to the fluidounce of water, has been used with advantage as a topical application to foul ulcers.

Each fluidrachm of the solution contains half a grain of arsenious acid. The average dose for an adult is ten drops two or three times a day. For the peculiar effects which it produces in common with the other arsenical preparations, the reader is referred to the article *Arsenious Acid.*

Duflos's antidote to the poisonous effects of Fowler's solution, and of the salts of the acids of arsenic generally, is the acetate of the sesquioxide of iron with excess of base, made by dissolving freshly precipitated sesquioxide in acetic acid to saturation, adding an equal quantity of the oxide to the solution, and diluting the whole with water to the consistence of cream. B.

LIQUOR POTASSÆ CITRATIS. *U. S. Solution of Citrate of Potassa.*

"Take of Citric Acid *half a troyounce;* Bicarbonate of Potassa *three hundred and thirty grains;* Water *half a pint.* Dissolve the Acid and Bicarbonate in the Water, and strain the solution through muslin." *U. S.*

MISTURA POTASSÆ CITRATIS. *U. S.* LIQUOR POTASSÆ CITRATIS. *U. S.* 1850. *Mixture of Citrate of Potassa. Solution of Citrate of Potassa. Neutral Mixture.*

"Take of Lemon-juice, fresh, *half a pint;* Bicarbonate of Potassa *a sufficient quantity.* Add the Bicarbonate gradually to the Lemon-juice until the acid is completely saturated; then strain through muslin." *U. S.*

We regret that two preparations so nearly identical in character, and associated in the Pharmacopœia of 1850, should have been separated in the present edition. We consider them here together, because essentially connected in practice; one being substituted for the other according to circumstances unconnected with their real remedial effects, as the presence or absence of fresh lemons or limes in the market, the taste of the patient, &c. In the present formula for solution of citrate of potassa the volatile oil of lemons has been omitted; which we should also regret, were it not easy to supply the omission extemporaneously if required. Two minims of the oil, rubbed up with the citric acid before it is dissolved, will materially improve the flavour, and give the preparation a closer resemblance to the original neutral mixture made from lemon-juice, from which it was copied. In both the above preparations, the potassa of the bicarbonate unites with the citric acid, and the carbonic acid is liberated. A portion of the latter remains in the solution, and a portion escapes with effervescence. The result, therefore, is a solution of citrate of potassa in water impregnated with carbonic acid. When lemon-juice is employed, the solution has a greenish-yellow colour; but prepared with the pure acid it is colourless. In the U. S. Pharmacopœia of 1850, bicarbonate of potassa was substituted for the carbonate before used. As the preparation was formerly made, a flocculent precipitate was apt to exhibit itself in small quantity, owing to the silicate of potassa generally present as an impurity in the carbonate. This gave up its base to the citric acid, and the silica was de-

posited in the state of a hydrate. The bicarbonate is free from this impurity, and consequently hydrated silica is not thrown down; nevertheless, the solution is still directed to be filtered; a direction which may be useful, when fresh lemon-juice is used, by separating the undissolved matters of the juice, and in other instances is only surplusage. About 48 grains of the crystals of the bicarbonate, 33 grains of the pure and perfectly dry carbonate, or 45 grains of the hydrated carbonate found in the shops, are sufficient to saturate a fluidounce of good lemon-juice; but the strength of the juice is variable, and the carbonate is apt to absorb moisture from the air, so that precision as to quantities cannot be readily attained. Hence the propriety of the direction in the process for the neutral mixture, to add the alkaline carbonate to saturation. The point of saturation may be determined by the cessation of effervescence, the absence of either an acid or alkaline taste, and still more accurately by litmus paper, which should not be rendered bright-red by the solution, nor blue if previously reddened by an acid.

The inequality of strength in the lemon-juice renders the neutral mixture prepared with it more or less uncertain; though, if the apothecary select ripe and sound fruit, and express the juice himself, the preparation will be found to approach sufficiently near a uniform standard for all practical purposes. Nevertheless, if the physician wish absolute precision, he may order the neutral mixture to be made with crystallized citric acid, as directed in the first officinal formula; or he may pursue the following plan, suggested in former editions of this work. Dissolve two drachms of bicarbonate of potassa in two fluidounces of water; saturate the solution with good fresh lemon-juice, and strain; and, lastly, add enough water to make the mixture measure six fluidounces. A fluidounce of this solution may be given for a dose.

Another mode of preparing the neutral mixture, officinal in 1850, but omitted in the present edition of the Pharmacopœia, is simply to dissolve citrate of potassa in water, in the proportion of six drachms to half a pint. The preparation may be improved in flavour, and rendered more agreeable to the stomach, by rubbing a drop or two of oil of lemon with the six drachms of citrate before dissolving it, and substituting carbonic acid water for water as the menstruum.

Effervescing Draught. Under this name, the citrate of potassa is often prepared extemporaneously, and given in the state of effervescence. The most convenient mode of exhibition is to add to a fluidounce of a mixture consisting of equal parts of lemon-juice and water, half a fluidounce of a solution containing fifteen grains of carbonate of potassa, or twenty grains of the bicarbonate. Should effervescence not occur, as sometimes happens, when the carbonate is used, in consequence of the weakness of the lemon-juice, more of the juice should be added; as, unless sufficient acid is present to neutralize the potassa, part of the carbonate passes into the state of bicarbonate, and the gas is thus prevented from escaping. A solution of citric acid of the strength of that directed in the officinal formula may be substituted for lemon-juice, if this is not to be had. The fifteen grains of carbonate of potassa above mentioned are scarcely sufficient to saturate the lemon-juice, if of ordinary strength; but a little excess of the acid renders the preparation more agreeable to the taste. Some prefer the bicarbonate in the preparation of the effervescing draught, because it will always effervesce with lemon-juice, no matter what may be the strength of the latter. But this is an objection. The carbonate serves, by the absence of effervescence, to indicate when the lemon-juice is very weak in acid; and the defect may then be easily remedied by the addition of more juice. When the bicarbonate is used, if there should be a deficiency of acid, it is not discovered; and the patient takes a considerable portion of undecomposed bicarbonate, instead of the full quantity of citrate intended.

Medical Properties and Uses. The solution of citrate of potassa has long been used under the name of *neutral mixture*, *saline mixture*, or *effervescing draught*. It is an excellent refrigerant diaphoretic, adapted to almost all cases of fever with a hot dry skin, and especially to the paroxysms of our remittent and intermittent fevers. The *effervescing draught* is peculiarly useful. The

carbonic acid serves to cover the taste of the citrate of potassa, and adds to the diaphoretic powers of the salt its own cordial influence upon the stomach. No preparation with which we are acquainted is equally efficacious in allaying irritability of stomach and producing diaphoresis in our remittent fevers. It is usually also very grateful to the patient. In order to increase the sedative and diaphoretic properties of the neutral mixture, it is customary to add to it a portion of tartar emetic; and a little sweet spirit of nitre will be found an excellent adjuvant in fevers with nervous disturbance. Should the solution irritate the bowels, as occasionally happens, it may be combined with a little laudanum or solution of sulphate of morphia. Sugar may be added if desired.

The dose of the officinal solution is a tablespoonful, or half a fluidounce, which should be somewhat diluted when taken. The whole of each effervescing draught, prepared as above stated, is to be taken at once. Each dose should be repeated every hour, two, or three hours, according to the urgency of the symptoms. W.

LIQUOR POTASSÆ EFFERVESCENS. *Br. Effervescing Solution of Potash.*

"Take of Bicarbonate of Potash *thirty grains;* Water *one pint* [Imperial measure]. Dissolve the Bicarbonate of Potash in the Water and filter the solution; then pass into it as much pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles securely closed, to prevent the escape of the compressed gas." *Br.*

This is one of the preparations of the old Colleges, which, discarded by the framers of the first British Pharmacopœia, has been admitted into the present edition of that work. It is nothing more than a solution of bicarbonate of potassa in carbonic acid water; and, in the pharmacy of this country, is more conveniently prepared for extemporaneous use by introducing a solution of the bicarbonate, of a given strength, or even the salt itself, into a strong green-glass bottle, and filling the bottle with carbonic acid water at the fountain. The proportion of the salt is far too small to the water for medical use. Little effect can be expected from bicarbonate of potassa as an antacid or antilithic, or even with a view to the alkalizing of the blood, in a dose less than thirty grains twice or thrice daily; and 20 fluidounces of liquid is much too large to be taken at once, or even in two doses. We have generally prescribed a solution containing a drachm of the bicarbonate in eight or ten fluidounces of carbonic acid water, to be given in two doses, with generally a little ginger syrup to improve the flavour. The advantages of carbonic acid as a vehicle are that it renders the medicine less disagreeable to the taste and more acceptable to the stomach, while by its stimulant impression it obviates the debility of the digestive organs often consequent on the use of alkaline medicines. W.

LIQUOR POTASSÆ PERMANGANATIS. *Br. Solution of Permanganate of Potash.*

"Take of Permanganate of Potash *eighty grains;* Distilled Water *one pint* [Imperial measure]. Dissolve." *Br.*

This is a simple solution of permanganate of potassa, in the proportion, as nearly as may be, of one part by weight to 110 parts of water; and is intended to be of standard strength. Though the quantities are augmented twenty-fold beyond those of the original Pharmacopœia, the proportion of the ingredients is the same. But, while for some purposes it is too strong, for others it is too feeble; and we prefer M. Reveil's normal solution of 10 parts to 90, so that the solution shall contain 10 per cent. of the salt, which may be used of its full strength when required, or diluted more or less according to circumstances. For details on this point the reader is referred to the article on permanganate of potassa (*page* 711). The British solution is used as a gargle in fetid affections of the throat, and for washing the hands after dissections, in the proportion of one part to forty of water. W.

LIQUOR SODÆ. *U. S.*, *Br.* *Solution of Soda.*

"Take of Carbonate of Soda *twenty-six troyounces;* Lime *eight troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Carbonate in three pints and a half of Distilled Water, and heat the solution to the boiling point. Mix the Lime with three pints of Distilled Water, and, having heated the mixture to the boiling point, add it to the solution of the Carbonate, and boil for ten minutes. Then transfer the whole to a muslin strainer, and, when the liquid portion has passed, add sufficient Distilled Water, through the strainer, to make the strained liquid measure six pints. Lastly, keep the liquid in well-stopped bottles of green glass. Solution of Soda has the sp. gr. 1·071, and contains 5·7 per cent. of hydrate of soda." *U. S.*

The British Pharmacopœia takes of Carbonate of Soda *twenty-eight ounces* [avoirdupois]; Slaked Lime *twelve ounces* [avoird.]; Distilled Water *one gallon* [Imperial measure], and prepares the Solution in the manner directed for Liquor Potassæ. The sp. gr. of the British solution is 1·047; and the proportion of hydrated soda contained in it is 4·1.

Solution of soda is prepared in the same way as solution of potassa. By a double decomposition between carbonate of soda and hydrate of lime, there are formed hydrate of soda in solution, and carbonate of lime which precipitates. In both the processes an excess of lime is used, which is necessary to ensure a full decomposition of the carbonate. One fluidounce of the British solution (458 grains) requires for neutralization 470 grain-measures of the *volumetric solution of oxalic acid*, and contains 18·8 grains of the hydrated alkali. *Br.*

Properties, &c. Solution of soda, sometimes called solution of *caustic* soda, is a colourless liquid, having a caustic taste and alkaline reaction. Its properties and tests are the same as those of solution of potassa, with the exception that no precipitate is produced by bichloride of platinum or tartaric acid. The alkali dissolved must be viewed as hydrate of soda (NaO,HO), consisting of one eq. of soda 31·3, and one of water 9=40·3.

LIQUOR SODÆ ARSENIATIS. *Br.* *Solution of Arseniate of Soda.*

"Take of Arseniate of Soda (rendered anhydrous by a heat not exceeding 300°) *four grains;* Distilled Water *one fluidounce.* Dissolve." *Br.*

This is simply an officinal form for the administration of arseniate of soda. (See *Sodæ Arsenias.*) The salt is directed to be dried, in order, we presume, that the solution may be of a uniform strength; as, from the mode in which the arseniate of soda is ordered to be prepared, it is scarcely possible that it should always contain precisely the same quantity of water of crystallization. It is important in drying it to limit the heat to 300°, lest a portion of the arsenic should be volatilized. The commencing dose is from three to five minims or drops, to be very cautiously increased if necessary. Its arsenical strength is about the same as that of the British solution of arsenite of potassa. W.

LIQUOR SODÆ CHLORINATÆ. *U.S.* LIQUOR SODÆ CHLORATÆ. *Br.* *Solution of Chlorinated Soda. Solution of Chloride of Soda. Labarraque's Disinfecting Liquid.*

"Take of Chlorinated Lime *twelve troyounces;* Carbonate of Soda *twenty-four troyounces;* Water *twelve pints.* Dissolve the Carbonate of Soda in three pints of the Water, with the aid of heat. Triturate the Chlorinated Lime, a little at a time, with small portions of the Water, gradually added, until a smooth, uniform mixture is obtained. Mix this intimately with the remainder of the Water, and set the mixture aside for twenty-four hours. Then decant the clear liquid, and, having transferred the residue to a muslin strainer, allow it to drain until sufficient liquid has passed to make, with the decanted liquid, eight pints. Mix the liquid thoroughly with the Solution of Carbonate of Soda, transfer the

mixture to a muslin strainer, and allow it to drain, adding water, if necessary, towards the close, until eleven pints and a half of liquid have passed. Lastly, keep the liquid in well-stopped bottles, protected from the light." *U. S.* The sp. gr. of this solution is 1·045.

"Take of Carbonate of Soda *twelve ounces* [avoirdupois]; Black Oxide of Manganese *four ounces* [avoird.]; Hydrochloric Acid *fifteen fluidounces* [Imperial measure]; Distilled Water *two pints* [Imp. meas.]. Dissolve the Carbonate of Soda in thirty-six [fluid]ounces of the Distilled Water and put the solution into a glass vessel. Mix the Oxide of Manganese and Hydrochloric Acid in a glass flask with a bent tube, attached, by means of a cork, to its mouth, apply a gentle heat, and with a suitable arrangement of apparatus cause the gas which is evolved to pass first through a wash-bottle containing four [fluid]ounces of Water, and then into the solution of carbonate of soda, regulating the heat so that the gas shall be slowly but constantly introduced. When the disengagement of chlorine has ceased, transfer the solution in which it has been absorbed to a stoppered bottle, and keep it in a cool and dark place." *Br.* The sp. gr. of this solution is 1·103.

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It was afterwards found to possess valuable therapeutic properties. The U. S. process is that of Payen, adopted in the French Codex of 1837. It consists in decomposing a solution of carbonate of soda by one of chlorinated lime. Carbonate of lime is precipitated and the chlorinated soda remains in solution. The proportion employed gives an excess of carbonate of soda, the presence of which renders the solution more permanent. The British process is that of Labarraque. All the chlorine generated from the prescribed quantity of materials for forming that gas, is passed into the solution of carbonate of soda; and, when the chlorine is limited to this quantity, no carbonic acid is disengaged. The chlorine is first passed through water to free it from muriatic acid, which, if suffered to come over, would convert the alkali into common salt.

The bicarbonate of soda is recommended instead of the carbonate, on account of the state of crystalline powder in which the carbonate of lime is precipitated, rendering its separation from the supernatant solution very easy, while the precipitate produced by the carbonate of soda is a kind of magma from which the liquor is not readily decanted. It is stated also that a little excess of the bicarbonate is useful in various ways. (*Ann. de Thérap.*, A.D. 1866, p. 107.)

Properties. The U. S. solution is transparent, of a greenish-yellow colour, a faint smell of chlorine, a sharp saline taste, and an alkaline reaction. With lime-water it yields a precipitate of carbonate of lime, known to be a carbonate by its dissolving with effervescence in an acid. This precipitate is caused by the excess of carbonate of soda. Owing to the presence of loosely combined chlorine, it rapidly destroys the colour of sulphate of indigo. It produces a copious, light-brown precipitate with the sulphate of iron. The British solution is a colourless alkaline liquid, of an astringent taste, and a feeble smell of chlorine. With muriatic acid it effervesces, and evolves chlorine and carbonic acid, and forms a solution which is not precipitated by bichloride of platinum, thus showing the absence of potassa. It is not precipitated by oxalate of ammonia, showing that it contains no lime. "Seventy grains added to a solution of 20 grains of iodide of potassium in four fluidounces of water, and acidulated with two fluidrachms of hydrochloric acid, require for the discharge of the brown colour which the mixture assumes, 500 grain-measures of the *volumetric solution of hyposulphite of soda.*" (Br.) This test is intended to determine the chlorine strength of the solution. The hydrochloric acid liberates the chlorine, which then separates from the iodide of potassium an equivalent quantity of iodine, by which the solution is rendered brown; and, the iodine being converted into hydriodic acid by the hyposulphite of soda, the solution again becomes colourless. The quantity of the solution of the latter salt required to bleach the liquid measures the proportion of iodine, and this that of the chlorine which separates it. The colour of turmeric is first rendered brown, and afterwards destroyed

When it is boiled, chlorine is not given off, nor is its bleaching property sensibly impaired; and, when carefully evaporated, a mass of damp crystals is obtained, which, when redissolved in water, possess the properties of the original liquid. Both solutions, when exposed to the air, absorb carbonic acid and slowly evolve chlorine. It is on this property of gradually evolving chlorine that their disinfecting power depends.

Nature and Composition. The chemical nature of these solutions is different. Assuming the chlorinated lime to be essentially hypochlorite of lime with chloride of calcium (see *page* 186), the U. S. solution, after decantation from the precipitated carbonate of lime, will contain *hypochlorite of soda* with *chloride of sodium;* $CaO,ClO+CaCl$ and $2(NaO,CO_2)=NaO,ClO+NaCl$ and $2(CaO,CO_2)$. Besides these there will be present more or less *carbonate of soda,* according as there happens to be in the chlorinated lime less or more chlorine to decompose it. In all cases, however, there will be an excess of carbonate of soda; as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formula. The constitution of the British preparation is more complicated. As it is a peculiarity in its formation that no carbonic acid is evolved, it is necessary to assume the presence of all the carbonic acid of the carbonate of soda; and hence it is considered to be a combination of *hypochlorite of soda, chloride of sodium,* and *bicarbonate of soda.* The reaction is supposed to take place between four eqs. of carbonate of soda and two of chlorine. By a transfer of carbonic acid from two eqs. of carbonate to the remaining two eqs. of the same salt, two eqs. of bicarbonate are formed, and two of soda left. The sodium and oxygen of one eq. of soda unite, each, with one eq. of chlorine, so as to form one eq. of chloride of sodium, and one of hypochlorous acid. This acid then unites with the remaining eq. of soda to form hypochlorite of soda. The view here taken makes the U. S. and British solutions analogous in constitution; but differing in one containing the carbonate, the other the bicarbonate of soda. In the latter, half the soda is bicarbonated; in the former, from a half to a third is monocarbonated, according to the quality of the chlorinated lime used. According to Millon's view, both solutions contain *oxychloride of sodium,* $Na\left\{\begin{matrix}O\\Cl_2\end{matrix}\right.$, or, which is the same thing, bichloride of soda (NaO,Cl_2); thus making the compound assimilate in constitution to the teroxide of sodium (NaO_3). On Millon's view, one eq. of carbonate of soda would decompose two of chloride of lime, with the result of forming one eq. of bichloride of soda, one of carbonate of lime, and one of free lime; $2(CaO,Cl)$ and $NaO,CO_2=NaO,Cl_2$ and CaO,CO_2 and CaO. M. Millon's view doubles the proportion of the chlorine to the soda. Mr. B. Kavanagh, of Dublin, finds that a solution of alum has its alumina precipitated upon being added to the British chlorinated soda liquid, without effervescence of carbonic acid, but with the evolution of chlorine on the application of heat. Hence he infers that the soda, not combined with carbonic acid in the preparation, is united with chlorine and not with hypochlorous acid, and, accordingly, conceives that he has proved the correctness of Millon's views. Upon the whole, analyses are wanting before we can determine the true constitution of the officinal solutions of chlorinated soda. The British solution, though made on Labarraque's plan, is considerably stronger than his preparation; for in the British process the carbonate is dissolved in about three times its weight of water, before the chlorine is transmitted; whereas Labarraque dissolved it in four times its weight.

Medical Properties and Uses. Solution of chlorinated soda is stimulant, antiseptic, and resolvent. Internally it has been employed in diseases termed *putrid* or *malignant,* as typhus fever, scarlatina maligna, &c. The conditions which indicate the propriety of its use are great prostration of strength, fetid evacuations, and dry and furred tongue. Under these circumstances it promotes urine, creates a moisture on the skin, and improves the secretions and evacuations. It has also been given in dysentery accompanied with peculiarly fetid stools, in dyspepsia attended with putrid eructations, and in glandular enlarge-

ments and chronic mucous discharges. Other complaints in which it has been recommended, are secondary syphilis, scrofula, bilious disorders, and chronic diseases of the skin. M. Chailly speaks in praise of it in suppressed or deficient menstruation. In asphyxia from sulphuretted hydrogen it forms, like chlorinated lime, an efficacious antidote. The dose is from thirty drops to a teaspoonful, given in a cupful of water or mild aqueous liquid, and repeated every two or three hours.

As a local remedy it is found useful in all affections attended with fetor, such as gangrenous,cancerous,scrofulous,and syphilitic ulcers,ulceration of the gums, carbuncle, ozæna, mortification, putrid sorethroat, &c. In these cases it is applied as a gargle, wash, ingredient of poultices, or imbibed by lint. In the sloughing of the fauces occurring in severe cases of scarlatina, Dr. Jackson, late of Northumberland, Pa., found it efficacious, used as a gargle, or injected into the throat. In smallpox Mr. John Gabb employed this solution with great benefit, as a wash and gargle for the mouth and throat, and as an application to the skin to allay itching. In the soremouth from ptyalism, it forms a good mouth-wash, when diluted with eight parts or more of water. In fetid discharges from the vagina, uterus, and bladder, it has been employed with advantage as an injection, diluted with from fifteen to thirty parts of water for the vagina and uterus, and with sixty parts when the object is to wash out the bladder by means of a double cannula. The solution of chlorinated soda has also been applied successfully to burns, and to cutaneous eruptions, particularly psoriasis, tinea capitis, scabies, and obstinate herpetic affections. In these cases it is diluted with from ten to thirty parts of water, the strength varying according to circumstances. For the cure of sore nipples, Dr. Chopin found nothing so successful as frequently repeated lotions with this solution. Dr. M. F. Gavin, of Boston, has found glycerin to be in many instances preferable as a diluent to water, as it tends to prevent irritation of the sound skin, and, in consequence of its non-drying properties, is not evaporated like the water. (*Boston Med. & Surg. Journ.*, Feb. 2, 1865, p. 47.)

Solution of chlorinated soda is a powerful disinfectant, better suited for disinfecting operations on a small scale than chlorinated lime. In the chambers of the sick, especially with infectious diseases, it is highly useful, sprinkled on the floor or bed, and added to the vessels intended to receive the excretions.

Off. Prep. Cataplasma Sodæ Chloratæ, *Br.* B.

LIQUOR SODÆ EFFERVESCENS. *Br. Effervescing Solution of Soda. Soda Water.*

This is prepared by the British Pharmacopœia from Bicarbonate of Soda and Water, in the same manner precisely and with the same quantities as the "*Effervescing Solution of Potash*" (see *page* 1270); and the remarks made upon that preparation are equally applicable to this. W.

LIQUOR STRYCHNIÆ. *Br. Solution of Strychnia.*

"Take of Strychnia, in crystals, *four grains;* Dilute Hydrochloric Acid *six minims;* Rectified Spirit *two fluidrachms;* Distilled Water *six fluidrachms* Mix the Hydrochloric Acid with four [fluid]drachms of the Water, and dissolve the Strychnia in the mixture by the aid of heat. Then add the Spirit and the remainder of the Water." *Br.*

This is in fact a solution of the muriate of strychnia. The spirit is added for its preservation. Two fluidrachms of it contain a grain of strychnia, and the commencing dose is from five to ten minims, equal respectively to the twenty-fourth and the twelfth of a grain of the alkaloid. W.

LIQUOR ZINCI CHLORIDI. *Br. Solution of Chloride of Zinc.*

"Take of Granulated Zinc *one pound* [avoirdupois]; Hydrochloric Acid *forty-four fluidounces* [Imperial measure]; Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce* [avoird.], or *a sufficiency;* Distilled Water *one pint* [Imp. meas.]. Mix the Hydrochloric Acid and Water in

a porcelain dish, add the Zinc, and apply a gentle heat to promote the action until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow the product to cool. Filter it into a bottle and add Solution of Chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odour of chlorine. Add the Carbonate of Zinc in small quantities at a time, and with renewed agitation, until a brown sediment appears. Filter the liquid into a porcelain basin, and evaporate until it is reduced to the bulk of two pints [Imp. meas.]." *Br.*

This preparation, formerly recognised as officinal in the Dublin Pharmacopœia, was discarded by the British when the codes of the three Colleges were consolidated, but has been resumed in the present edition. The formula differs somewhat from that of the Dublin Pharmacopœia; but at each step of the two processes the object aimed at appears to be the same.

The chloride of zinc is made, in the usual way, by dissolving zinc in muriatic acid. The solution of chlorine is added in order to convert any iron present into sesquichloride, from which it is afterwards precipitated by the carbonate of zinc. In the Dublin process the former object was accomplished by the use of solution of chlorinated lime, the latter by chalk. This is a decided improvement; as the use of the chalk as a precipitant introduced into the preparation some chloride of calcium; while the carbonate of zinc adds to the chloride of zinc in solution. The preparation is completed by bringing it to a certain bulk by the addition of distilled water, and by filtration to separate the precipitated iron and any excess of the carbonate.

As procured by the Dublin process, solution of chloride of zinc was a dense, colourless liquid, having a burning, nauseous taste even when dilute. It contained 175 grains of zinc in the Imp. fluidounce, and had the sp. gr. 1·593. The British solution must be of the same or very nearly the same strength; as the proportion of zinc to the volume of the resulting solution is the same in the two codes. This solution is equivalent to Burnett's disinfecting fluid noticed below. It is a powerful disinfectant, and, when applied, duly diluted with water, to cancerous and other offensive ulcers, destroys their fetor so long as the dressings are kept moist with it. The solution is recommended by M. Gaudriot in gonorrhœa in both sexes, as having remarkable remedial powers. For men he uses an injection, composed of from twenty-four to thirty-six drops in four fluidounces of water. A small quantity only is injected about an inch up the urethra, two or three times a day. For women he employs a vaginal suppository, formed of five drops of the solution, half a grain of sulphate of morphia, and three drachms of a paste consisting of a drachm and a half of starch, a drachm of mucilage of tragacanth, and half a drachm of sugar. The suppository is introduced every day, or every second day.

Burnett's disinfecting fluid, like the officinal solution, is an aqueous solution of chloride of zinc. It contains 200 grains of zinc in each Imperial fluidounce, and has the sp. gr. 2. It is, therefore, considerably stronger than the Dublin solution. It is so called after Sir William Burnett, who introduced it into use, in 1840, as a powerful deodorizing and disinfecting agent in neutralizing noxious effluvia, and in arresting animal and vegetable decomposition. Diluted with water it forms Sir William's patent preservative against the dry rot. The concurrent testimony of a number of observers shows that it acts as an excellent disinfectant for ships, hospitals, dissecting rooms, water-closets, privies, &c. (See Extracts from the *British Navy Reports* on chloride of zinc as a disinfectant, in the *Lond. Med. Times and Gaz.*, Oct. 1853, p. 341.) Injected into the blood-vessels, it preserves bodies for dissection, without impairing their texture, and is said not to injure the knives employed; but the accuracy of the latter statement is doubtful. The advantage is claimed for it, that, while it destroys putrid odours, it has no smell of its own. For preserving anatomical subjects, one part of the disinfecting fluid to eighteen of water will form a solution of the proper strength. For disinfecting operations on a large scale, a pint of the fluid may be mixed with four gallons of water. B.

LITHIA.

Preparation of Lithia.

LITHIÆ CITRAS. *Br. Citrate of Lithia.*

"Take of Carbonate of Lithia *fifty grains;* Citric Acid, in crystals, *ninety grains;* Warm Distilled Water *one fluidounce.* Dissolve the Citric Acid in the Water, and add the Carbonate of Lithia, in successive portions, applying heat until effervescence ceases, and a perfect solution is obtained. Evaporate by a steam or sand-bath till water ceases to escape, and the residue is converted into a viscid liquid. This should be dried in an oven or air-chamber at the temperature of about 240°, then rapidly pulverized, and enclosed in a stoppered bottle." *Br.*

The British Pharmacopœia gives, as the composition of citrate of lithia, three eqs. of lithia and one of citric acid ($3LO,C_{12}H_5O_{11}$); this acid being tribasic. The eq. of carbonate of lithia being 37, and three eqs. entering into the constitution of the salt, 111 parts of the carbonate will of course require 201 parts or one eq. of crystallized citric acid for saturation. Consequently, to saturate the 50 grains of carbonate of lithia directed by the Pharmacopœia, 90·54 grains of the crystallized acid will be required; so that there is a slight deficiency on the part of the acid; whereas it should be in slight excess, and, according to Mr. Squire, 100 grains of the acid should be used instead of 90 grains.

Citrate of Lithia, thus prepared, is in the form of a white powder, deliquescent, and soluble, without residue, in 2·5 parts of water. (*Squire.*) Heated to redness it blackens, evolving inflammable gases; and the residue, neutralized by hydrochloric acid, yields with rectified spirit a solution which burns with a crimson flame. (*Br.*) This test proves that the base is lithia, and the acid organic. That the salt is a citrate will be shown by its solution becoming turbid when boiled with lime-water, but clear again on cooling. (*Brande and Taylor.*) "Twenty grains of it, burned at a low red heat, with free access of air, leave 10·6 grains of white residue." (*Br.*) In other words, 20 grains of the salt yield 10·6 grains of carbonate of lithia; for all the acid with its carbon must be consumed in the process. If the salt consist, as stated in the Pharmacopœia, of 3 eqs. of lithia = 45, and one eq. of citric acid ($C_{12}H_5O_{11}$) = 165, without water, 210 parts of it should yield 111 parts of the carbonate, which is almost exactly the result given by the Pharmacopœia; so that the citrate must be considered as anhydrous.

Medical Properties and Uses. These are essentially the same as those of the carbonate, as, before entering the circulation, the citric acid is decomposed, and the lithia circulates with the blood, and passes out with the urine in the form of carbonate. While thus capable of producing the antacid, antilithic, and diuretic effects of the carbonate, it has the advantages over that salt of having a less disagreeable taste, and of being less disposed to irritate the stomach; the same advantages that, in many instances, the citrate of potassa has over the carbonate of that alkali. The dose is stated at from five to ten grains; but probably much more might sometimes be given with advantage, especially when employed with the object of dissolving depositions of urate of soda. W.

LOTIONES.

Lotions.

This class has been introduced into the Br. Pharmacopœia, in order to give officinal recognition to two preparations, the *black wash* or *lotio nigra*, and the *yellow wash* or *lotio flava*, which have been long in use, and which will be found treated of under Calomel and Corrosive Sublimate at *pages* 1206 and 1201 of this work. Nothing more will be necessary here than to give the British formulas.

LOTIO HYDRARGYRI FLAVA. *Br. Yellow Mercurial Lotion.*

"Take of Perchloride of Mercury [Corrosive Sublimate] *eighteen grains;* Solution of Lime *ten fluidounces.* Mix."

LOTIO HYDRARGYRI NIGRA. *Br. Black Mercurial Lotion.*

"Take of Subchloride of Mercury [Calomel] *thirty grains;* Solution of Lime *ten fluidounces.* Mix." W.

MAGNESIA.

Preparations of Magnesia.

MAGNESIA. *U.S.* MAGNESIA LEVIS. *Br. Magnesia.*

"Take of Carbonate of Magnesia *a convenient quantity.* Put it into an earthen vessel, and expose it to a red heat for two hours, or until the carbonic acid is entirely expelled." *U. S.*

In the British Pharmacopœia directions are given for preparing two forms of magnesia, one called *Magnesia Levis*, or *Light Magnesia*, from the *Light Carbonate*, and the other simply *Magnesia* from the heavy carbonate, which it designates as *Carbonate of Magnesia.* It is the former which corresponds with our ordinary magnesia.

"Take of Light Carbonate of Magnesia *four ounces.* Put it into a Cornish or Hessian crucible closed loosely by a lid, and expose it to a low red heat until a small quantity, taken from the centre of the crucible, when it has been cooled, and dropped into diluted sulphuric acid, causes no effervescence." *Br.*

MAGNESIA. *Br.* This is directed, in the British Pharmacopœia, to be prepared precisely in the same manner as light magnesia, using, however, the heavy carbonate, named by it Carbonate of Magnesia. The two varieties differ, according to the Br. Pharmacopœia, only in their weight in the same bulk; the volumes corresponding to the same weight being to each other in the ratio of three and one-half to one.

By exposure to a red heat, the water and carbonic acid of the carbonate of magnesia are expelled, and the earth is obtained pure. According to Dr. Black, the carbonate loses seven-twelfths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent., of which from 15 to 20 per cent. is water. About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbonic acid. (*Duncan.*) A more certain indication, however, is the absence of effervescence when muriatic acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbonic acid, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to ensure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible; and, as in consequence of its levity it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk; but the French pharmaceutical writers direct that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression.*

* In a paper by M. A. Vée (*Journ. de Pharm.*, Avril, 1860, p. 84), it is stated that the magnesia of commerce, in consequence of imperfect preparation, is often found dense, granular, harsh, and of difficult solubility in the acids. To remedy this inconvenience the only method heretofore known was to prepare it in small quantities, and to stir the magnesia during calcination with an iron spoon. The difficulty in preparing it properly on the large scale depends upon the unequal action of the heat on large masses, so that the outer part becomes heated in excess before the inner is sufficiently so. To remedy this inconvenience M. Vée uses a furnace and crucible of a peculiar shape, so arranged that the magnesia may not be in layers thicker than seven centimetres (2·7 inches), may be exposed equably to heat, and not longer exposed than may be necessary for its decomposition. For an account of the apparatus, and of the proper method of managing the process, the reader is referred to the *Am. Journ. of Pharm.*, Nov. 1862, p. 522. (*Note to the twelfth edition.*)

The officinal direction, to keep the magnesia, after it has been prepared, in well-stopped glass vessels, is founded on the fact that it absorbs carbonic acid and water from the air; but, as the absorption of the acid goes on very slowly, and that of water does not injure the preparation, the caution is often neglected in the shops. The great bulk of the earth renders its introduction into small bottles inconvenient. A four-ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration; and four times the quantity may be thus got into the same space. The density of *Henry's Magnesia*, which is at least four times that of the earth prepared in the ordinary way, has been ascribed to this cause. It has also been attributed to the influence of intense heat employed in the calcination. The conjecture has even been advanced, that this magnesia, which has enjoyed so great a popularity in England and this country, is prepared by precipitating a solution of sulphate of magnesia by caustic potassa; as the earth afforded by this plan is comparatively dense. It is asserted that the magnesia, prepared from the carbonate procured by precipitating the sulphate of magnesia with carbonate of soda, is softer to the touch, and bears a closer resemblance to Henry's than that prepared from the ordinary carbonate. The fact is explained by the presence in common magnesia of a little sulphate of potassa, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica, which originally existed in the carbonate of potassa employed to decompose the sulphate of magnesia, and of which the carbonate of soda is destitute. According to Mr. Richard Phillips, jun., if equivalent quantities of crystallized sulphate of magnesia and crystallized carbonate of soda be boiled together in water, the mixture evaporated to dryness, the residual salts calcined, and the sulphate of soda dissolved out by water, the magnesia obtained will be dense. (See *Am. Journ. of Pharm.*, xvi. 118.) By packing the carbonate closely in the crucible, or by moistening and then compressing it strongly in a cloth, before calcination, a heavy magnesia is obtained. The advantages of Henry's magnesia, independently of the convenience of its less bulk, are its greater softness, and more ready miscibility with water. Preparations similar to Henry's are made by T. J. Husband and by Charles Ellis, of Philadelphia, and sold under the names respectively of *Husband's* and of *Ellis's Magnesia.**

* The three kinds of heavy magnesia sold in our market have been examined by Prof. Procter, with the following results. All are heavier than common magnesia, more readily miscible with water, smoother upon the tongue, and of a less quickly developed taste; but they differ in these respects, Henry's standing first, Husband's second, and Ellis's last. But the two latter are much more readily acted on by acids than Henry's, differing in this respect little from each other. Both, moreover, though less readily miscible with water than Henry's, are longer retained in suspension, and Ellis's exceeds Husband's in this quality. In reference, therefore, to mere facility of administration and to taste, it appears that the imported magnesia has the advantage; but for forming liquid mixtures, and for rapidity of antacid action, the American are preferable. Husband's contained 7 per cent. of combined water; the two others lost at a red heat only seven-tenths of one per cent. (*Am. Journ. of Pharm.*, xxii. 383.)

Dr. Pereira found *light magnesia*, under the microscope, to exhibit the same forms observed in the light carbonate; namely, one portion was amorphous and of a flocculent or granular consistence, and another was composed of fragments of prismatic crystals; while the *heavy magnesia* was homogeneous, exhibiting no traces of crystals, and consisting of minute granules more or less cohering into small soft balls or masses. (*Pharm. Journ.*, viii. 235.)—*Note to the ninth edition.*

In reference to the preparation of heavy magnesia, Mr. T. H. Barr, after trying various methods, obtained the best results either by precipitating a hot concentrated solution of sulphate of magnesia with a like solution of carbonate of soda, or by decomposing chloride of magnesium by heat. (*Am. Journ. of Pharm.*, xxvi. 193.)

Mr. Thomas Weaver proposes the following ready method of preparing a heavy magnesia, which, as we have been informed, yields a good product, having not only the recommendation of density, but that also of smoothness, which is a no less desirable quality. "Take of sulphate of magnesia ℥iv, ʒij; *bi*carbonate of soda ℥iij. Dissolve the sulphate in six ounces of water, add a few drops of nitric acid, and boil for 15 or 20 minutes; then add sufficient carbonate of soda, dissolved in a little water, to produce a slight precipitate, and continue boiling for some time; filter, and set aside to cool. Triturate the *bi*carbonate

Properties, &c. Magnesia is a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2·3. It was deemed infusible till melted by means of the compound blowpipe of Dr. Hare. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature. It is almost insoluble, requiring, according to Dr. Fyfe, 5142 parts of water at 60°, and 36,000 parts of boiling water for solution. Water thus impregnated has no effect on vegetable colours; but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one equivalent of magnesium 12, and one of oxygen 8 = 20. *Magnesium* is a white, very brilliant metal, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. It burns with great facility, and yields by its combustion a light which is said to be more intense than that from any other earthly source. (*Journ. de Pharm.*, 4e sér., ii. 320.)* There is a hydrate of magnesia consisting of one equiv. of the earth and one of water. Magnesia forms with nitric and muriatic acids, salts which are soluble in alcohol, and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydrate, and by the carbonates of potassa and soda as a carbonate; but it is not precipitated by the alkaline bicarbonates, nor by common carbonate of ammonia.

Magnesia is liable to contain, as impurities, carbonate of magnesia, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. The presence of carbonate of magnesia is indicated by effervescence when the earth is dissolved in muriatic acid. Lime, which is a very frequent impurity, and imparts to the magnesia a more strongly alkaline and more disagreeable taste, is detected by oxalate of ammonia or bicarbonate of potassa. Neither of these salts disturbs a neutral solution of pure magnesia in a dilute acid; but, if lime is present, both produce a precipitate, the former of oxalate, the latter of carbonate of lime. But, according to Wittstein, oxalate of lime is soluble in the neutral salts of magnesia, requiring 50 parts of chloride of magnesium, and 90 of the sulphate of magnesia; and consequently there might be no precipitate, or one redissolved by the liquid, should the proportion of lime be very small. (*Journ. de Pharm.*, 4e sér., iii. 216.) As magnesia is completely dissolved by muriatic acid, silica and other impurities insoluble in that acid would be left behind. Alumina is indicated by the production of a precipitate when ammonia is added in excess to a solution of fifty grains of magnesia in a fluidounce of muriatic acid. (*Christison's Dispensatory.*) If the magnesia contain a soluble sulphate or carbonate, chloride of barium will reveal it by producing a precipitate with water digested on the magnesia.

of soda with about eight ounces of cold water, and add it to the cold solution of sulphate of magnesia. After frequent agitation, filter, transfer to a porcelain capsule, and boil quickly till reduced to a small bulk. Collect the precipitate on a filter, wash thoroughly, and, when nearly dry, transfer to a crucible free from iron, and calcine, bearing in mind the suggestion of Mr. Barr, that a low heat just approaching redness, and long continued, will ensure a much finer product than a high heat for a short time." The object of the nitric acid is to peroxidize any iron present in the sulphate, and the subsequent addition of carbonate of soda, followed by ebullition, is to precipitate the ferruginous oxide. Cold solutions of bicarbonate of soda and sulphate of magnesia do not react on each other; but, when the excess of carbonic acid is driven off by boiling, a precipitation takes place of carbonate of magnesia, which affords a denser magnesia by calcination than can be obtained by the use of carbonate of soda. (*Am. Journ. of Pharm.*, xxviii. 214.) —*Note to the eleventh edition.*

* M. Z. Roussin has made some valuable suggestions in relation to magnesium. This metal possesses a remarkable property, that, namely, of precipitating many metals from their solution in a metallic state; and may thus render great service to toxicology, both as an antidote and a test. Thus, in the case of a poisonous metallic salt in the stomach, it may if swallowed render the poison for a time innoxious by reducing the metal; and, after death from such a cause, or in life, through the vomited liquid, may detect the poison, if inserted into the complex liquid, by throwing down the metal. The magnesium itself is harmless. (See *Am. Journ. of Pharm.*, Sept. 1866, p. 455.)—*Note to the thirteenth edition.*

Medical Properties and Uses. Magnesia is antacid and laxative; and is much used, under the name of *calcined magnesia*, in dyspepsia, sick headache, gout, and other complaints attended with sour stomach and constipation. It is also a favourite remedy in the complaints of children, in which acidity of the primæ viæ is often a prominent symptom. Its antacid properties render it useful in gravel attended with an excessive secretion of uric acid. Its advantages over carbonate of magnesia are that it may be given in a smaller dose, and does not occasion flatulence. The dose as a laxative is from thirty grains to a drachm; as an antacid merely, or antilithic, from ten to thirty grains twice a day. When it meets with no acid, it is apt to linger in the stomach or bowels, and may in that case be followed by lemonade. It should be administered in water or milk, and thoroughly triturated so as to render the mixture uniform. If mixed with less than 14 or 15 times its weight of water, and allowed to stand for a day or two, magnesia is apt to form a more or less concrete mass, owing to the production of a hydrate of the earth, and the solidification of a portion of the water. This change does not take place, or at least takes place much less readily, when magnesia already saturated with moisture is employed instead of that freshly calcined. It has been conjectured that anhydrous magnesia might prove injurious in the stomach by solidifying its liquid contents; and the earth which has become saturated with moisture by exposure to a damp air is preferably recommended. Freshly precipitated hydrate of magnesia will serve as an antidote to arsenious acid, though less efficient than hydrated sesquioxide of iron.

MELLITA.

Preparations of Honey.

Honey is used in pharmacy chiefly as the vehicle of more active medicines. It is said to have this advantage over syrup, that its preparations are less apt to become candied; but, as it contains principles which disagree with the stomach in many persons, and as its variable consistence prevents the same exact precision in regard to proportion as is attainable with a solution of pure sugar, it is at present little employed. The preparations in which honey and vinegar are combined are called *Oxymels.* The *Oxymel of Squill*, of the former U. S. and London Pharmacopœias, has been omitted in the existing edition of our national code.

Medicated honeys are of a proper consistence, if, when a small quantity, allowed to cool upon a plate, is divided by the edge of a spoon, the portions do not readily coalesce. A more accurate criterion, however, is their specific gravity, which should be 1·319 (35° B.) at ordinary temperatures, and 1·261 (30° B.) at the boiling point of water. The specific gravity is most readily determined by means of the saccharometer. W.

MEL DESPUMATUM. *U. S.* Mel Depuratum. *Br. Clarified Honey.*

"Take of Honey *a convenient quantity.* Melt it by means of a water-bath, and then remove the scum." *U. S.*

"Take of Honey *five pounds.* Melt the honey in a water-bath, and strain, while hot, through flannel, previously moistened with warm water." *Br.*

Honey, by the heat of the water-bath, becomes so fluid that the wax and other lighter impurities which it contains rise to the surface, and may be skimmed off; while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom.

The following method of clarifying honey has been practised in France. Take of white honey 3000 parts; water 750 parts; carbonate of lime, powdered and washed, 96 parts. Mix them in a suitable vessel, and boil for three minutes, stirring constantly. Then add 96 parts of animal charcoal, previously

washed, heated to redness, powdered, and sifted, and boil for a few minutes. Lastly, add the whites of two eggs beat up with 500 parts of water, and bring the liquid to the boiling point. Withdraw the vessel from the fire, and, after the mixture has cooled for 15 minutes, strain it through flannel, and repeat the straining till the liquid passes perfectly clear. Should it not have a due consistence, it should be concentrated sufficiently by a quick boiling. The carbonate of lime serves to saturate any acid in the honey, which might favour the formation of glucose, and thus increase the tendency to granulation.

The French Codex simply directs six pounds of white honey to be heated with two pounds of water, skimmed, concentrated to 30° B. while boiling hot, and then strained through flannel.

The following method of clarifying honey is recommended by André von Hirschberg. Boil 25 lbs. of honey, to which half the quantity of water has been added, with a pulp obtained by stirring three sheets of white blotting-paper with water, over a slow fire, till the paper is reduced to minute fibres. When the mixture cools, put it into a woollen filtering bag, previously moistened, and allow the honey to pass. It comes away quite clear. The paper pulp may then be washed, and the dark liquid which passes, evaporated by a water-bath to the proper consistence. (See *Pharm. Journ.*, ix. 543.)

Another process, recommended by A. Hofmann, is to dissolve 28 lbs. of honey in twice its weight of water, heat the solution to the boiling point, and then add a solution of three drachms of gelatin in three times its weight of water, and afterwards an aqueous solution of one drachm of tannin, or an infusion of two drachms of galls. The mixture is to be well stirred, and kept hot for an hour. Lastly, seven-eighths of the honey may be drawn off clear, the remainder filtered through flannel, and the whole evaporated. (*Ibid.*, xv. 121.)

Honey clarified with carbonate of lime and and animal charcoal, as in the first process described, is as clear and colourless as syrup made with sugar, but still retains a peculiar flavour. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

Off. Prep. Confectio Aromatica, *U. S.;* Confectio Opii, *U. S.;* Confectio Piperis, *Br.;* Confectio Rosæ, *U. S.;* Confectio Scammonii, *Br.;* Confectio Terebinthinæ, *Br.;* Mel Boracis, *Br.;* Mel Rosæ, *U. S.;* Mel Sodæ Boratis, *U. S.;* Oxymel, *Br.;* Oxymel Scillæ, *Br.;* Pilulæ Ferri Carbonatis, *U. S.;* Pilulæ Quiniæ Sulphatis, *U. S.;* Tinctura Cardamomi Composita, *U. S.;* Tinctura Opii Camphorata, *U. S.* W.

MEL ROSÆ. *U. S. Honey of Roses.*

"Take of Red Rose, in moderately fine powder, *two troyounces;* Clarified Honey *twenty-five troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with half a fluidounce of Diluted Alcohol, pack it firmly in a conical glass percolator, and gradually pour Diluted Alcohol upon it until six fluidrachms of filtered liquid have passed. Set this aside, and continue the percolation until half a pint more of liquid is obtained. Evaporate this, by means of a water-bath, to ten fluidrachms, add the reserved liquid, and mix the whole with the Clarified Honey." *U. S.*

Though one of the officinals in the late London and Edinburgh Pharmacopœias, the Honey of Roses has been dropped in the British.

The U. S. formula is based on that of Prof. Grahame, of Baltimore. (See *Am. Journ. of Pharm.*, Sept. 1859, p. 443.) The object in reserving a portion of the first tincture, in the process, is to avoid the evaporation of the volatile oil in the concentration of the liquid, and thus to preserve the flavour as well as the astringency of the roses. Honey of roses forms a pleasant addition to the gargles employed in inflammation and ulceration of the mouth and throat. W.

MEL SODÆ BORATIS. *U. S.* MEL BORACIS. *Br. Honey of Borate of Soda. Honey of Borax.*

"Take of Borate of Soda, in fine powder, *sixty grains;* Clarified Honey *a troyounce.* Mix them." *U. S.*

"Take of Borax, in fine powder, *sixty-four grains;* Clarified Honey *an ounce* [avoirdupois]. Mix." *Br.*

This preparation might well be left to extemporaneous prescription. It is used in the thrush of infants, and aphthous ulcerations of the mouth. W.

OXYMEL. *Br. Oxymel.*

"Take of Clarified Honey *forty ounces* [avoirdupois]; Acetic Acid *five fluidounces;* Distilled Water *five fluidounces.* Liquefy the Honey by heat, and mix with it the Acetic Acid and Water." *Br.*

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines, and to impart flavour to drinks in febrile complaints. W.

OXYMEL SCILLÆ. *Br. Oxymel of Squill.*

"Take of Vinegar of Squill *a pint* [Imperial measure]; Clarified Honey *two pounds* [avoirdupois]. Mix, and evaporate by a water-bath, until the product, when cold, shall have a specific gravity of 1·32." *Br.*

After a long vogue, this preparation fell into such neglect that it was abandoned by the Pharmacopœias. Its reintroduction, however, into the Br. Pharmacopœia indicates that it is still prescribed. It has the virtues of squill, but is in no respect superior to the syrup. It is chiefly used as an expectorant in chronic catarrh, humoral asthma, hooping-cough, and generally in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration. The dose is from one to two fluidrachms. In large doses it is emetic, and as such may sometimes be given with advantage in infantile croup and catarrh. W.

MISTURÆ.

Mixtures.

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in watery fluids, by the intervention of gum arabic, sugar, the yelk of eggs, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is properly called an *emulsion.* The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines; and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of a uniform and perfect mixture. As a general rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the watery vehicle is added. In the case of the liquid balsams and oils, if gum arabic be employed as the intermedium, it should be previously brought to the state of mucilage of the consistence directed in the U. S. Pharmacopœia.* The white of eggs has been frequently ordered by physicians as the suspending substance; but it is inferior for this purpose to the yelk, or to gum arabic. When the white is used it should be well beaten, and incorporated with the oleaginous or balsamic substances before the water is added. Mixtures are generally the objects of extemporaneous prescription; but a few have been deemed of sufficient importance to merit a place in the Pharmacopœias. They should be prepared only when wanted for use. The Mixtures, formerly officinal, which were discarded in the original preparation of the Br. Pharmacopœia, are *Mistura Acaciæ*, Ed., *Mistura Althææ*, Ed., *Mistura Camphoræ cum Magnesia*, Ed., *Mistura Ferri Aromatica*, Dub.,

* The proportion of gum and water necessary to make a good emulsion with the fixed oils varies with the oil. Thus, while castor oil requires only two drachms of the gum and three drachms of water to the ounce, most other fixed oils require half their weight of gum, and a weight of water equal to half that of the oil and gum united. These quantities being well rubbed together, any desirable amount of water may afterwards be gradually added, and will readily incorporate with the other ingredients. (Overbeck. *Pharm. Cent. Blatt*, A. D. 1851, p. 95.)

Mistura Gentianæ Composita, Lond., and *Mistura Spiritus Vini Gallici*, Lond. Of these, however, the last three have been readmitted into the present edition. W.

MISTURA AMMONIACI. *U. S.*, *Br.* *Mixture of Ammoniac.*

"Take of Ammoniac *one hundred and twenty grains;* Water *half a pint.* Rub the Ammoniac with the Water, gradually added, until they are thoroughly mixed, and strain." *U. S.*

"Take of Ammoniacum, in coarse powder, *a quarter of an ounce* [avoirdupois]; Distilled Water *eight fluidounces.* Triturate the Ammoniacum with the Water, gradually added, until the mixture assumes a milky appearance, then strain through muslin." *Br.*

In this mixture the insoluble part of the ammoniac is suspended by means of the gum, imparting a milky appearance to the preparation, which, from this circumstance, was formerly called *lac ammoniaci* or *milk of ammoniac.* The greater portion of the resin subsides upon standing. The mixture is slightly curdled by acids. The dose is from one to two tablespoonfuls. W.

MISTURA AMYGDALÆ. *U. S.*, *Br.* *Mixture of Almond. Almond Mixture. Almond Emulsion.*

"Take of Sweet Almond *half a troyounce;* Gum Arabic, in fine powder, *thirty grains;* Sugar *one hundred and twenty grains;* Distilled Water *eight fluidounces.* Having blanched the Almond, beat it with the Gum Arabic and Sugar, in a mortar, until they are thoroughly mixed; then rub the mixture with the Distilled Water gradually added, and strain." *U. S.*

"Take of Compound Powder of Almonds *two ounces and a half* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Rub the powder with a little of the Water into a thin paste, then add the remainder of the Water, and strain through muslin." *Br.*

These preparations are essentially the same; the gum and sugar, which enter into the U. S. formula directly, being ingredients of the compound powder of almonds of the British. The processes are both preferable to that of the old London Pharmacopœia, in which a confection of almonds was employed; as this preparation was liable to spoil quickly when kept. The gum arabic in these formulas is introduced, not so much for its demulcent properties, as to assist in the suspension of the insoluble ingredients of the almonds. The same formula will answer for the preparation of an *emulsion of bitter almonds*, which may be preferred to the present when a slight influence of hydrocyanic acid is desired.

The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water; and with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when not very impure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The mixture is not permanent. Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. The preparation is closely analogous to milk in chemical relations and appearance. In warm weather it soon becomes sour, and unfit for use.

The almond mixture has a bland taste, and may be used as an agreeable, nutritive demulcent in catarrhal and dysenteric affections, and irritation of the urinary passages. To be of service it must be freely employed. From two to eight fluidounces may be taken at once. It is occasionally employed as the vehicle of less agreeable medicines; but should not be used in connection with any considerable quantity of tinctures, acidulous salts, or other substances containing an excess of acid. W.

MISTURA ASSAFŒTIDÆ. *U. S.* *Assafetida Mixture.*

"Take of Assafetida *one hundred and twenty grains;* Water *half a pint.*

Rub the Assafetida with the Water, gradually added, until they are thoroughly mixed." *U. S.*

This mixture, from its whiteness and opacity, is frequently called *lac assafœtidæ* or *milk of assafetida.* It is, as a general rule, the best form for the administration of this antispasmodic, being less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable smell and taste are, however, objections, which induce a frequent preference of the last-mentioned preparation. It is very often employed as an enema. The dose is from one to two tablespoonfuls frequently repeated. From two to four fluidounces may be given by the rectum.* W.

MISTURA CHLOROFORMI. *U. S. Mixture of Chloroform.*

"Take of Purified Chloroform *half a troyounce;* Camphor *sixty grains;* the yolk of *one* Egg; Water *six fluidounces.* Rub the yolk in a mortar, first by itself, then with the Camphor, previously dissolved in the Chloroform, and lastly, with the Water, gradually added, so as to make a uniform mixture." *U. S.*

In consequence of the great facility with which camphor dissolves in chloroform, and the ready miscibility of the solution, by the intervention of the yelk of eggs, with water, this mixture affords an easy and agreeable method of administering these medicines jointly. Besides, in consequence of the preservative influence of the chloroform, it will keep long unchanged. The dose is one or two tablespoonfuls. W.

MISTURA CREASOTI. *Br. Creasote Mixture.*

"Take of Creasote, Glacial Acetic Acid, of each, *sixteen minims;* Spirit of Juniper *half a fluidrachm;* Syrup *one fluidounce;* Distilled Water *fifteen fluidounces.* Mix the Creasote with the Acetic Acid, gradually add the Water, and lastly the Syrup and Spirit of Juniper." *Br.*

The dose of this mixture is a fluidounce, containing a minim of creasote. W.

MISTURA CRETÆ. *U. S., Br. Chalk Mixture.*

"Take of Prepared Chalk *half a troyounce;* Sugar [refined], Gum Arabic, in fine powder, each, *one hundred and twenty grains;* Cinnamon Water, Water, each, *four fluidounces.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Prepared Chalk *a quarter of an ounce* [avoirdupois]; Gum Acacia, in powder, *a quarter of an ounce* [avoird.]; Syrup *half a fluidounce;* Cinnamon Water *seven fluidounces and a half.* Triturate the Chalk and Gum Acacia with the Cinnamon Water, then add the Syrup and mix." *Br.*

This mixture is a convenient form for administering chalk, and is much employed in looseness of the bowels accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency. The dose is a tablespoonful frequently repeated. W.

MISTURA FERRI AROMATICA. *Br. Aromatic Mixture of Iron.*

"Take of Pale Cinchona Bark, in powder, *one ounce;* Calumba Root, in

* *Syrup of Assafetida.* Such a preparation has been proposed by Mr. Richard Peltz. He has found the following formula to answer the purpose best. Take of assafetida ℥j, boiling water Oj, sugar lbsij. Rub the assafetida with a part of the water so as to make a uniform paste, then gradually add the remainder of the water, strain, and add the sugar, heating moderately till it is dissolved. This has a less disagreeable taste than the mixture, and keeps much better, remaining several months without change, while the latter is often altered in a short time. The dose is the same as that of the mixture. (*Am. Journ. of Pharm.*, xxiv. 313.)—*Note to the tenth edition.*

Wine of Assafetida. Mr. H. N. Rittenhouse proposes a concentrated wine of assafetida, as affording an easy method of preparing the mixture, which, when called for in haste, cannot always be furnished in due time, from the amount of trituration required. He rubs half an ounce of the gum-resin with ten fluidrachms of white wine until the former is suspended. Two ounces of the wine are thus obtained; and, as each drachm contains fifteen grains of assafetida, it is easy to prepare the mixture of the officinal strength, by simply mixing the wine in due proportion with water. (*Am. Journ. of Pharm.*, xxvii. 216.)—*Note to the eleventh edition.*

coarse powder, *half an ounce;* Cloves, bruised, *a quarter of an ounce;* Fine Iron Wire *half an ounce;* Compound Tincture of Cardamoms *three fluidounces;* Tincture of Orange Peel *half a fluidounce;* Peppermint Water *a sufficiency.* Macerate the Cinchona Bark, Calumba Root, Cloves, and Iron with twelve fluidounces of the Peppermint Water, in a closed vessel, for three days, agitating occasionally; then filter the liquid, adding as much Peppermint Water to the filter as will make the product measure twelve and a half fluidounces; to this add the tinctures, and preserve the mixture in a well-stopped bottle." *Br.* The weights used in this process are the avoirdupois, and the measures the Imperial.

This is an old Dublin formula, which, we presume, bases its claim to an officinal position upon the favourable experience of physicians who have employed it; for it is certainly not one which, with the light of modern chemistry, would be apt to be formed. The following comment upon it is from the U. S. Dispensatory of 1862.

This is an aromatic infusion of Peruvian bark and columbo, and has no claim to the title given it in the Pharmacopœia, as it contains but a minute proportion of iron, insufficient for remedial effect. In consequence of the action of the vegetable principles on the wire, enough of the metal is taken up to impart a greenish-black colour to the liquor; but the quantity is scarcely appreciable; as the iron appears to be hardly diminished by the process. The mixture may be given as a tonic in the dose of one or two fluidounces. W.

MISTURA FERRI COMPOSITA. *U. S., Br. Compound Mixture of Iron.*

"Take of Myrrh, Sugar [refined], each, *sixty grains;* Carbonate of Potassa *twenty-five grains;* Sulphate of Iron, in coarse powder, *twenty grains;* Spirit of Lavender *half a fluidounce;* Rose Water *seven fluidounces and a half.* Rub the Myrrh, Sugar, and Carbonate of Potassa with the Rose Water, gradually added, then with the Spirit of Lavender, and, lastly, with the Sulphate of Iron; and pour the mixture immediately into a bottle, which must be well stopped." *U. S.*

"Take of Sulphate of Iron *twenty-five grains;* Carbonate of Potash *thirty grains;* Myrrh, Refined Sugar, of each, *sixty grains;* Spirit of Nutmeg *four fluidrachms;* Rose Water *nine and a half fluidounces.* Reduce the Myrrh to powder, add the Carbonate of Potash and Sugar, and triturate them with a small quantity of the Rose Water, so as to form a thin paste; then gradually add more Rose Water and the Spirit of Nutmeg, continuing the trituration and further addition of Rose Water until about eight fluidounces of a milky liquid is formed; then add the Sulphate of Iron dissolved in the remainder of the Rose Water, mix them together thoroughly, and preserve the mixture as much as possible from contact with the air." *Br.*

This is very nearly the same with the celebrated tonic or antihectic myrrh mixture of Dr. Griffith. The sulphate of iron is decomposed by the carbonate of potassa, with the production of sulphate of potassa and carbonate of protoxide of iron; while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish colour, which it loses upon exposure to the air, in consequence of the conversion of the protoxide of iron of the carbonate into the red or sesquioxide. It may, however, be kept for some time without change, if the vessel in which it is contained be well closed; but the best plan is to prepare it only when wanted for use. The sugar contained in it contributes somewhat to retard the further oxidation of the protoxide of iron, and, if considerably increased in amount, would act still more efficiently. The finest pieces of myrrh in lump should be selected, and rubbed down for the occasion with a little of the rose-water; as the powdered myrrh of the shops is often impure, and otherwise does not make a good mixture, owing mainly to its loss of volatile oil.

This mixture is a good tonic in debility of the digestive organs, especially

when attended with derangement of the menstrual function. Hence it is used with advantage in chlorosis and hysterical affections. It has been also much employed in the hectic fever of phthisis and chronic catarrh. It is contraindicated by the existence of inflammation of the gastric mucous membrane. The dose is one or two fluidounces two or three times a day. W.

MISTURA GENTIANÆ. *Br. Infusum Gentianæ Compositum. Br.* 1864. *Gentian Mixture.*

"Take of Gentian Root, sliced, *a quarter of an ounce;* Bitter Orange Peel, cut small, Coriander Fruit, bruised, each, *thirty grains;* Proof Spirit *two fluidounces;* Distilled Water *eight fluidounces.* Macerate the Gentian, Orange Peel, and Coriander in the Proof Spirit, for two hours, then add the Water. Macerate again for two hours, and strain through calico." *Br.*

According to the strict pharmaceutical meaning of mixtures, this preparation does not belong to that class, being in fact a compound infusion, as it was named in the first edition of the British Pharmacopœia; but as it was thought proper, in the present edition, to introduce the old London Compound Infusion of Gentian, it became necessary to find another name for the preparation here given, and it was consequently placed among the mixtures. The British Gentian Mixture is almost identical with the U. S. *Compound Infusion of Gentian*, to which the reader is referred for further remarks on the subject. (See *page* 1229.) The dose is a fluidounce. W.

MISTURA GLYCYRRHIZÆ COMPOSITA. *U. S. Compound Mixture of Liquorice. Brown Mixture.*

"Take of Liquorice [extract], in fine powder, Sugar, in coarse powder, Gum Arabic, in fine powder, each, *half a troyounce;* Camphorated Tincture of Opium *two fluidounces;* Wine of Antimony *a fluidounce;* Spirit of Nitrous Ether *half a fluidounce;* Water *twelve fluidounces.* Rub the Liquorice, Sugar, and Gum Arabic with the Water, gradually added; then add the other ingredients, and mix the whole together." *U. S.*

This is an exceedingly popular cough mixture, which was made officinal in the U. S. Pharmacopœia of 1850. The spirit of nitrous ether is probably useful by somewhat retarding decomposition. The preparation is applicable to the advanced stages of catarrhal affections, after expectoration has become established. The dose is a tablespoonful for an adult; a teaspoonful for a child two years old. It should be well shaken when administered. W.

MISTURA GUAIACI. *Br. Guaiac Mixture.*

"Take of Guaiacum Resin, in powder, Refined Sugar, of each, *half an ounce* [avoirdupois]; Gum Acacia, powdered, *a quarter of an ounce* [avoird.]; Cinnamon Water *one pint* [Imperial measure]. Triturate the Guaiacum with the Sugar and the Gum, adding gradually the Cinnamon Water." *Br.*

For the changes of colour which the Guaiac in this mixture undergoes, and produces in other substances, see *Guaiaci Resina*, p. 441. From one to four tablespoonfuls may be given for a dose, and repeated two or three times a day, or more frequently. W.

MISTURA POTASSÆ CITRATIS. *U. S.* Liquor Potassæ Citratis. *U. S.* 1850. *Mixture of Citrate of Potassa. Neutral Mixture.*

"Take of Lemon Juice, fresh, *half a pint;* Bicarbonate of Potassa *a sufficient quantity.* Add the Bicarbonate gradually to the Lemon Juice until the acid is completely saturated; then strain through muslin." *U. S.*

For remarks on this preparation, see *Liquor Potassæ Citratis*, page 1268. The dose is a tablespoonful or half a fluidounce, which, when taken, may be somewhat diluted with water. W.

MISTURA SCAMMONII. *Br. Scammony Mixture.*

"Take of Resin of Scammony *four grains;* Milk *two* [illegible]*ounces.* Triturate the Resin of Scammony with a little of the Milk, and continue the tritu

ration, gradually adding the remainder of the Milk, until a uniform emulsion is obtained." *Br.*

This officinal is an imitation of a mixture recommended by Planche. The resin of scammony mixes admirably with the vehicle, and forms an emulsion scarcely distinguishable in appearance or taste from rich milk. Of course, it should be prepared only when wanted for immediate use. The whole is to be taken for a dose. W.

MISTURA SENNÆ COMPOSITA. *Br. Compound Mixture of Senna.*

"Take of Sulphate of Magnesia *four ounces* [avoirdupois]; Extract of Liquorice *half an ounce* [avoird.]; Tincture of Senna *two and a half fluidounces* [Imperial measure]; Compound Tincture of Cardamoms *ten fluidrachms*; Infusion of Senna *a sufficiency*. Dissolve the Sulphate of Magnesia and Extract of Liquorice in fourteen fluidounces [Imp. meas.] of the Infusion of Senna, with the aid of a gentle heat, then add the Tinctures, and sufficient Infusion of Senna to make one pint [Imp. meas.]." *Br.*

This is a new form of compound infusion of senna, called commonly the *black draught*. We prefer the form given under *Infusum Sennæ* (*page* 1232), as being more easily prepared, and quite as efficient. The dose of this mixture is given in the Br. Pharmacopœia as from one fluidounce to one and a half. W.

MISTURA SPIRITUS VINI GALLICI. *Br. Mixture of Spirit of French Wine. Brandy Mixture.*

"Take of Spirit of French Wine [Brandy], Cinnamon Water, of each, *four fluidounces*; the Yolk of two Eggs; Refined Sugar *half an ounce* [avoirdupois]. Rub the Yolk and Sugar together, then add the Cinnamon Water and Spirit." *Br.*

This is a formula of the London College, which was dropped on the preparation of the first British Pharmacopœia, to be taken up again in the present edition. It is a nutritious and stimulant draught, applicable to the sinking stage of low forms of fever; but scarcely entitled to a place in the Pharmacopœia. At least, if egg-nog is admitted, there would seem to be no good reason for excluding milk-punch. The dose of it is one or two fluidounces. W.

MORPHIA.

Preparations of Morphia.

MORPHIA. *U. S. Morphia.*

"Take of Opium, sliced, *twelve troyounces*; Water of Ammonia *six fluidounces*; Animal Charcoal, in fine powder, Alcohol, Distilled Water, each, *a sufficient quantity*. Macerate the Opium with four pints of Distilled Water for twenty-four hours, and, having worked it with the hand, again macerate for twenty-four hours, and strain. In like manner, macerate the residue twice successively with the same quantity of Distilled Water, and strain. Mix the infusions, evaporate to six pints, and filter; then add five pints of Alcohol, and afterwards three fluidounces of the Water of Ammonia, previously mixed with half a pint of Alcohol. After twenty-four hours, pour in the remainder of the Water of Ammonia, mixed, as before, with half a pint of Alcohol; and set the liquid aside for twenty-four hours that crystals may form. To purify these, boil them with two pints of Alcohol until they are dissolved, filter the solution, while hot, through Animal Charcoal, and set it aside to crystallize." *U. S.*

This process will be better understood by a previous acquaintance with the properties and chemical relations of the substance in question.

Morphia crystallizes from alcohol in the form of small, colourless, shining crystals. It is inodorous and bitter. Exposed to a moderate heat, it loses its water of crystallization and the crystalline form, becoming white and opaque. At a higher temperature it melts, forming a yellowish liquid, which becomes

white and crystalline upon cooling. Heated in the open air, it burns with a bright flame, and at a red heat is wholly dissipated. In the products resulting from the combustion of opium or morphia, this alkaloid may be detected, proving that it is partly volatilized, when burned. (Descharmes, *Arch. Gén.*, Fév. 1855, p. 240.) According to Mr. Guy, morphia melts at 330°, and sublimes at 340°, leaving a carbonaceous residue. (*Pharm. Journ. and Trans.*, Feb. 1868. p. 375.) It is insoluble or nearly so in cold water, soluble in rather less than 100 parts of water at 212°, slightly soluble in cold alcohol, and freely so in boiling alcohol, which deposits it upon cooling. It is dissolved also by the fixed and volatile oils, but very slightly if at all by ether. Both morphia and its salts are insoluble in chloroform. (Lepage, *Journ. de Pharm.*, xxv. 258.) Morphia in solution is to a considerable extent absorbed by animal charcoal, which, though it will part with most of the alkaloid to alcohol, cannot be wholly deprived of it by repeated washings with that liquid, whether cold or hot. (Lefort, *Journ. de Pharm.*, Août, 1861, p. 98.) Its solution restores the blue colour of litmus paper reddened by acids, and turns the yellow of turmeric to brown. With the acids it forms salts, which are generally soluble, and are decomposed by the alkalies. The solutions of potassa and soda also dissolve morphia, which is precipitated slowly from them on exposure to the air, in consequence of the absorption of carbonic acid. Solution of ammonia has to a certain extent the same solvent power; and hence the necessity, in precipitating morphia by this alkali, not to employ it in great excess. Solution of iodine with iodide of potassium precipitates the salts of morphia in aqueous solution. With chlorine water morphia and its salts assume an orange colour, and the same effect is produced on them by solution of chlorinated soda. (Fairthorne, *Am. Journ. of Pharm.*, xxviii. 9.) By the contact of nitric acid, they assume a blood-red colour, which ultimately changes to yellow; and this is one of the tests of morphia; but, as the same change of colour is produced with brucia and impure strychnia, it cannot be relied on in the absence of other evidence. Nitric acid also produces a red colour with oil of cloves, but in this case the red does not change to yellow. When added to a solution of iodic acid, or an acidulous iodate, morphia and its salts redden the liquid and set iodine free. (*Serullas.*) This is a very delicate test, but is not conclusive, as various other organic substances act in a similar manner. M. J. Lefort, however, has found that the colour produced by these substances is removed by ammonia, while the redness produced with morphia is greatly intensified by addition of that alkali. This test, thus modified by the addition of ammonia, is so delicate that, according to M. Lefort, it will detect one part of morphia in 10,000 parts of a liquid holding it in solution. (*Journ. de Pharm.*, Août, 1861, p. 113.]* Morphia and its salts assume a fine blue colour with the

* When a mixture of a little morphia and *iodic acid* with a few drops of water is gently heated in a capsule, a series of explosions is produced, with the evolution of gas. The same thing happens with other vegetable alkaloids treated in the same manner; and Dr. Brett proposes this reaction of iodic acid, which takes place with no other organic substance that he has tried, as a test of the alkaloids. (*Pharm. Journ.*, xvi. 211.)

Unsized Paper in testing for Morphia. Most of the tests of morphia will act more satisfactorily if the alkaloid or its salts be fixed in unsized paper, which will then exhibit the characteristic changes of colour when exposed to the agents employed. Paper may be prepared for this purpose by dipping slips of perfectly white filtering paper several times in the liquid to be examined, and, after each immersion, drying the paper by a moderate heat. (Lefort, *Journ. de Pharm.*, Août, 1861, p. 106.)—*Note to the twelfth edition.*

Stas's method of extracting the Alkaloids from Mixtures. To separate the alkaloid from foreign matters, the mixture is treated alternately with water and alcohol in different degrees of concentration; the liquors thus obtained are filtered; tartaric or oxalic acid, but preferably the former, is added in excess; the mixture is heated to 160° or 170° F.; the whole is placed upon a filter; the deposited matter is washed with concentrated alcohol; the alcoholic solution is evaporated at a temperature not exceeding 95° F.; the residue is introduced into a small bottle; a solution of caustic potassa or soda is added, little by little, and afterwards four or five times the measure of ether; the mixture is shaken and then allowed to stand; and, finally, the ether is decanted, and yields the alkaloid by spontaneous evaporation. Stas included morphia among the alkaloids thus separable, though known to be nearly insoluble in ether; but Lefort has shown that the process is not applicable to

sesquichloride of iron, and the salts of the sesquioxide; at least this is true of the alkaloid, its sulphate, acetate, and oxalate; and the same effect will be produced by the other salts, if previously decomposed by an alkali; but that this test should be satisfactory, it is necessary to operate on morphia either in powder or concentrated solution. (*Lefort.*) Water, acids, and alkalies, added in large quantity to the blue compound formed, destroy its colour. According to Pelletier, moreover, there occasionally exists in opium a principle called by him pseudomorphia, which becomes red under the action of nitric acid, and changes the salts of sesquioxide of iron blue, and yet is destitute of poisonous properties; so that the occurrence of these phenomena, in any medico-legal case, cannot be considered as certain evidence of the presence of morphia. (See *Am. Journ. of Pharm.*, viii. 77.) The terchloride of gold precipitates morphia first yellow, then bluish, and lastly violet. (*Larocque* and *Thibierge.*) Peroxide of copper and oxide of silver are precipitated by morphia from their ammoniacal solutions, and ferridcyanide of potassium in solution is reduced by it to the ferrocyanide. (*Chem. Gaz.*, no. 367, p. 54.) A solution of acetate or sulphate of morphia, containing only one part of the salt in 100, precipitates silver from a solution of the nitrate of that metal. (*Horsley.*) Morphia is precipitated from its solutions by potassa or soda, and redissolved by an excess of the alkali. Infusions of galls and other vegetable substances containing tannic acid precipitate morphia in the state of a tannate, which is soluble in acetic acid; but according to Dublanc, the alkaloid is not precipitated by pure gallic acid. If ammonia be added to a mixture of the solutions of chlorine and morphia, a dark-brown colour is produced, which is destroyed by a further addition of chlorine. The proportion of the constituents of morphia is somewhat differently given by different writers. According to the most recent authorities, anhydrous morphia consists of thirty-four eqs. of carbon 204, nineteen of hydrogen 19, one of nitrogen 14, and six of oxygen 48 = 285, to which in the crystals are added two eqs. of water 18, or about 5·8 per cent. ($C_{34}H_{19}NO_6$,2HO).

Various processes for preparing morphia have been employed. In most of them the morphia is extracted from opium by maceration with water either pure or acidulated, is then precipitated by ammonia, and afterwards purified by the agency of alcohol, or by repeated solution in a dilute acid and precipitation.

Sertürner, the discoverer of morphia, made an infusion of opium in distilled water, precipitated the morphia by ammonia in excess, dissolved the precipitate in dilute sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol, and crystallization.

The process of the French Codex is a modification of that of Sertürner. It is as follows. "Take of opium 1000 parts, solution of ammonia a sufficient quantity. Exhaust the opium, by means of cold water, of all its parts soluble in that menstruum. For that purpose, it is sufficient to treat the opium, four times consecutively, with ten parts of water to one of the drug, provided care be taken to macerate the opium for some hours, and to work it with the hands. Filter the liquors, and evaporate them to a quarter of their volume. Then add sufficient ammonia to render the liquor very sensibly alkaline. Boil for some minutes, always maintaining a slight excess of ammonia. Upon cooling, the morphia, impure and much coloured, will be precipitated in granular crystals, which are to be washed with cold water. Reduce this coloured morphia to powder, macerate it for twelve hours in alcohol of 24° Cartier [sp. gr. about 0·900]; then decant the alcoholic liquid; dissolve the residuary morphia, already in great measure deprived of colour by the cold alcohol, in boiling alcohol of 33° Cartier [sp. gr. about 0·850]; add to the solution a little animal charcoal, and filter. Upon cooling, the morphia crystallizes in colourless needles. In this state the morphia always retains some narcotina, to free it from which, boil it with sulphuric ether in a matrass with a long neck surmounted by a refrigerator."

that alkaloid. (*Journ. de Pharm.*, Août, 1861, p. 99.) M. Alfred Valser, however, has ascertained that, if acetic ether be substituted for ether, the process is equally applicable to morphia. (See *Am. Journ. of Pharm.*, Sept. 1864, p. 439.)—*Note to the twelfth edition.*

The process of the U. S. Pharmacopœia is an improvement upon the foregoing, and is essentially the same as this of Dr. Edward Staples, published in the *Journal of the Philadelphia College of Pharmacy* (i. 15). Without repeating a description of the process, we shall make such remarks upon its several steps, as appear to us likely to be of practical advantage. The employment of water as the solvent is justified by the almost universal practice. It is true that dilute acetic acid has sometimes been employed, and Vogel states that the product thus obtained is much greater than when water alone is used. But, when the opium is properly comminuted, either by being reduced to a coarse powder when dry, or by being finely sliced in its ordinary state, water alone will be found sufficiently to extract the morphia, by a protracted maceration or digestion in successive portions of water, assisted by kneading, as directed in the Pharmacopœia. The acids have this disadvantage, that they dissolve more of the narcotina than pure water, and thus render the ultimate product more impure; for the narcotina which is originally taken up continues associated with the morphia in all the subsequent steps of the process. It has been proposed to expose the opium to fermentation with water and yeast, in order to facilitate the extraction of the morphia. By this plan M. Blondeau succeeded in procuring more of the alkaline principle than he could obtain by the ordinary mode; and his results were confirmed by the experiments of MM. Robiquet and Guibourt. According to these latter chemists, no alcohol is produced during the fermentation, which appears to act merely by disengaging the morphia from the combinations in which it naturally exists, and which tend to counteract the solvent power of the menstruum. Alcohol was proposed as the solvent by M. Guillermond, but is liable to the objection that it dissolves also the resin, a portion of which is afterwards precipitated with the morphia, and embarrasses the process. Much of the resin, however, may be separated by distilling most of the alcohol from the tincture, and then adding water. The resin is precipitated, and the liquor may now be treated in the same manner as the aqueous infusion.* On the whole, however, the officinal mode of extraction will probably be found most satisfactory; and Mohr states that opium thus exhausted yields no more morphia even to muriatic acid; but he recommends that each maceration should be followed by strong expression. The infusion of opium having been prepared, the next object is to decompose the meconate or other salt of morphia contained in it. For this purpose solution of ammonia is added, which seizes the acid, and precipitates the organic alkali; but much colouring matter is thrown down along with the latter, occasioning some trouble to separate it, unless measures are taken to obviate this effect. The object is gained by mixing the infusion with alcohol, previously to the addition of the ammonia, and by employing the solution of ammonia itself in connection with alcohol, as directed in the Pharmacopœia. This is the peculiarity and chief merit of the process of Dr. Staples. By the presence of the alcohol in all parts of the liquor, the colouring matter is dissolved as soon as it is separated by the ammonia, and the morphia is thus precipitated in a much purer state. The advantage of adding the ammonia in separate portions is, that the morphia, being thus more slowly disengaged, can be more completely deprived of its impurities by the alcohol of the mixture, than if the whole were liberated at once. It is necessary to be careful that the ammonia be not in great excess; as it has the property, under these circumstances, of dissolving the mor-

* By a modification of the process of Guillermond, MM. Desmedt have succeeded in extracting all the morphia from opium, perfectly free from narcotina. Of crude opium 60 parts were treated with 240 of alcohol at 71° centigrade (160° F.), and expressed when cold; the residue was then treated in the same manner with 160 parts of alcohol; the liquor was introduced into a bottle well stopped; next day a copious crystallization of narcotina appeared, without the least morphia; the liquid was decanted, and, on the addition of 4 parts of ammonia, furnished a considerable quantity of morphia, free from narcotina. To the mother-liquor a little distilled water was added, and the mixture was kept at the temperature of 24° C. In two days an additional quantity of the crystals of morphia was obtained equally free from narcotina. The opium was completely exhausted, and the 60 parts employed furnished 5 parts of morphia. (*Annuaire de Thérap.*, 1852, p. 81.)—*Note to the tenth edition.*

phia in some degree, and will therefore lessen the product, while waste is incurred by its own unnecessary consumption. Very little more should be added than is sufficient to saturate the acid present. The solution of ammonia of the shops is often much below the officinal standard, and this should always be attended to in the process. Alcohol is mixed with the ammonia before it is added, in order that every particle of the separated morphia may come in contact with the particles of this fluid, and thus have the opportunity of being deprived of colouring matter. The crystals of morphia obtained by this first operation have a light-yellowish colour, and are much purer than when no alcohol is added to the infusion before the precipitation by ammonia. According to Dr. Staples, opium yields from 10 to 12·5 per cent. of the crystals. Their purification by solution in boiling alcohol is the concluding step of the operation. The liquid, on cooling, deposits the morphia crystallized, and nearly free from colour. As cold alcohol retains a portion of morphia, it should not be employed too largely. Alcohol somewhat reduced by water is preferable to highly rectified spirit; as it is less capable of holding the morphia in solution when cold. It is sufficiently strong at 25° Baumé (sp. gr. 0·9032). The impure morphia remaining in the alcohol may be obtained by distilling off the latter, and, when sufficiently accumulated, may be purified by a separate operation. The crystals of morphia may also be purified by solution in dilute sulphuric acid, digestion with purified animal charcoal, filtration, and precipitation by ammonia. If alcohol be added to the solution previously to the ammonia, the digestion with animal charcoal may be dispensed with, as the alcohol retains the colouring matter. Morphia procured in this way always contains narcotina, from which it may be freed by ether, or in some of the modes hereafter to be indicated.

Magnesia was employed by Robiquet instead of ammonia. But his process was soon abandoned; as it was found to occupy more time, to require a greater consumption of alcohol, and to be attended with a greater loss of morphia in consequence of the previous washing, than the processes in which ammonia was employed as the precipitant. For an account of it the reader is referred to former editions of this work.

A process for extracting morphia without the employment of alcohol was devised by MM. Henry, jun., and Plisson. The opium was exhausted by water acidulated with muriatic acid; the resulting solution was sufficiently concentrated, then filtered, and decomposed by ammonia; the precipitate was washed and treated with muriatic acid to saturation; and the muriatic solution was boiled with animal charcoal, filtered, and evaporated to the point of crystallization. The crystals of muriate of morphia thus obtained were pressed, purified by repeated solution and crystallization, and finally decomposed by ammonia. (*Journ. de Chim. Méd.*, Mars, 1828.)

Somewhat similar to this is the process of Gregory, of Edinburgh, by which muriate of morphia is obtained by double decomposition between chloride of calcium and the meconate of morphia of the opium, and the muriate thus obtained is decomposed by ammonia. This process was adopted by the Ed. College for the preparation of muriate of morphia; and is retained in the present Br. Pharmacopœia. It will be sufficiently explained under *Muriate of Morphia.*

Mohr has proposed a process founded on the solubility of morphia in water mixed with lime, which he recommends as the shortest and easiest method of procuring the alkaloid, without the use of alcohol, and without the possibility of contamination from narcotina. Opium is three or four times successively macerated with three parts of water, and each time strongly expressed. The liquors are then added to a boiling-hot milk of lime, containing a quantity of lime equal to about a sixth or a quarter of the opium used; and the mixture is boiled for a few minutes. It is then strained through linen, and the residue washed with boiling water and expressed. The whole of the narcotina is left behind, as not a trace of it can be discovered in the filtered liquor. The liquor thus obtained is evaporated till reduced to double the weight of the opium, then quickly filtered through paper, and heated to ebullition. Muriate of ammonia is now

added to it in the proportion of 1 part to 16 of the opium used; and the morphia is abundantly precipitated. The use of animal charcoal is unnecessary in the process, as the lime acts even more powerfully as a decolorizing agent. The crystallized morphia obtained is somewhat coloured, but may be rendered pure by solution in dilute muriatic acid, boiling with milk of lime, filtration, and precipitation by muriate of ammonia. (*Annal. der Pharm.*, xxxv. 119.)

Various other processes, or modifications of those above described, have been proposed; but, for the preparation of small quantities of morphia by the apothecary, none are probably better adapted than that of the U. S. Pharmacopœia.

It has been already stated that morphia, obtained in the ordinary manner, contains a considerable proportion of narcotina. It is highly probable that this ingredient exercises no influence, either beneficial or injurious, upon the operation of the morphia; but as the contrary has been supposed, various methods have been employed for separating it. The simplest and easiest is to submit the mixture to the action of ether, which dissolves the narcotina and leaves the morphia. The agency of acetic acid may also be resorted to. Distilled vinegar, or diluted acetic acid of the same strength, will dissolve the morphia and leave the narcotina, and the former may be recovered from the acetic solution by saturating the acid with ammonia. Another mode is to dissolve the mixed bases in strong acetic acid (of 7° Baumé, or sp. gr. 1·0511, for example), and expose the solution to heat. The narcotina is deposited, and the morphia, remaining in solution, may be precipitated by diluting the liquid and adding ammonia. (*Journ. de Pharm.*, xvii. 640.) Wittstock advises one of the following modes. Dissolve the impure morphia in dilute muriatic acid, evaporate to the point of crystallization, and strongly express the crystals, which consist solely of the muriate of morphia, the narcotina being retained in the mother-waters:—or saturate the muriatic solution with common salt, which will render the liquor milky, and cause the narcotina to separate after some days; then precipitate the morphia by ammonia:—or pour into the diluted muriatic solution a weak ley of caustic potassa, which, if in slight excess, will dissolve the morphia at the moment of its separation, while the narcotina is precipitated; then immediately filter the liquor, and separate the morphia by neutralizing the alkali. If the potassa is in great excess, a little of the narcotina is redissolved. (Berzelius, *Traité de Chim.*) Mohr recommends to dissolve the morphia in dilute muriatic acid, and to boil the solution with lime, which throws down the narcotina and holds the morphia dissolved. The liquid being filtered yields the morphia upon the addition of muriate of ammonia. (*Annal. der Pharm.*, xxv. 123.)

The proportion of pure morphia which Turkey opium is capable of affording varies from 9 per cent. or less to 14 per cent., according to the quality of the drug; but much less than the least quantity mentioned is often obtained, in consequence of the incomplete exhaustion of the opium, the loss in the process for preparing it, or inferiority in the quality of the drug.

Medical Properties. There can be no doubt that morphia is the chief narcotic principle of opium, from which, however, it differs somewhat in its mode of action. The difference probably arises in part from the peculiar state of combination in which morphia exists in opium, but chiefly from other narcotic principles being associated with it. That the former is in some degree the cause, would seem from the circumstance that, long before the discovery of this alkaloid, preparations of opium were habitually used, in which the properties of the medicine were somewhat similarly modified by the agency of vinegar, lemon-juice, or other vegetable acid. In consequence of its insolubility in water, morphia in its pure state is less certain in its effects than some of its saline compounds; as the mode and degree of its action must, in some measure, depend on the presence or absence of acid in the stomach, and perhaps on the peculiar character of the acid. Its salts are therefore always preferred. The acetate, sulphate, and muriate have been employed. Between these there is a great similarity of action, and what may be said of one, in regard to its therapeutical effects, will equally apply to the others. They have the anodyne, soporific, and diaphoretic properties of opium,

but are less stimulant, less disposed to constipate the bowels, and less apt to leave behind them headache, nausea, or other unpleasant effect. They are usually also more acceptable to an irritated stomach, and may be retained, when opium or its tincture would be rejected. That they operate by entering the circulation is proved by the detection of morphia in the urine, though it is said not to be eliminated by the skin. (*Lefort.*) They are applicable to all cases where the object is to relieve pain, quiet restlessness, promote sleep, or allay nervous irritation in any shape; but are less efficient than opium in the suppression of morbid discharges, and as stimulants in low forms of disease. A great advantage which they possess is the convenience of their external application to blistered surfaces, and the certainty of their effects when thus applied. In cases which do not admit of the internal use of opium or its preparations, the acetate or sulphate of morphia, sprinkled, in triple the ordinary dose, upon a blistered surface denuded of the cuticle, will be found to exercise upon the system all the influence it is capable of exerting when taken into the stomach. Applied in this manner, these salts are peculiarly useful in relieving violent neuralgic pains, and controlling obstinate sickness of the stomach. When intended to act on the system through the medium of the skin, they should be applied preferably to the epigastrium; when to act locally, as near the affected part as possible. Solutions of the salts of morphia also sometimes operate very favourably, both generally and locally, when injected, by means of a sharp-pointed syringe, adapted to the purpose, into the areolar tissue beneath the skin. Given in doses nearly but not quite sufficient to produce sleep, they sometimes occasion a very troublesome condition of the brain, amounting almost to delirium; but this always subsides spontaneously, or vanishes immediately upon the increase of the dose. An embrocation for external use may be made by dissolving muriate or acetate of morphia in glycerin, which takes up about 5 per cent. of these salts at common temperatures, and more with the aid of heat. (*Journ. de Pharm.*, xxvi. 90.) Oleic acid has also been proposed as a vehicle for morphia externally used, as it dissolves both the alkaloid and its salts perfectly in considerable proportion. A liniment has been proposed, consisting of 300 parts of oleic acid and 1 of morphia, scented with a little oil of bergamot. (*Ibid.*, xxvi. 302.)

In overdoses, morphia and its salts produce the effects of narcotic poisons, though not perhaps equally with a quantity of opium equivalent in anodyne operation. An instance of death from the injection of three grains of morphia into the rectum is recorded by Dr. Anstie, of England, but the age of the patient is not mentioned. (*Med. Times and Gaz.*, Dec. 1862, p. 317.) The toxicological treatment is precisely the same as in the case of laudanum. (See *Opium.*) Strong coffee has been employed with great apparent advantage as an antidote.

As the proportion of acid necessary to neutralize morphia is very small, the dose of the alkaloid is the same as that of its salts. One-sixth of a grain may be considered about equivalent to a grain of opium of the medium strength.

Off. Prep. Morphiæ Acetas, *U. S.;* Morphiæ Murias, *U. S.;* Morphiæ Sulphas, *U.S.* W.

MORPHIÆ ACETAS. *U.S.*, *Br. Acetate of Morphia.*

"Take of Morphia, in fine powder, freed from narcotina by the action of Ether, *a troyounce;* Distilled Water *half a pint;* Acetic Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water; then carefully drop in Acetic Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, to the consistence of syrup. Lastly, dry the salt with a gentle heat, and rub it into powder." *U. S.*

"Take of Hydrochlorate of Morphia *two ounces* [avoirdupois]; Solution of Ammonia, Acetic Acid, Distilled Water, of each, *a sufficiency.* Dissolve the Hydrochlorate of Morphia in *one pint* [Imperial measure] of Distilled Water, and add Solution of Ammonia until the Morphia is precipitated and the liquid rendered slightly alkaline. Collect the precipitate on a filter, wash it with Distilled Water; then, having transferred it to a porcelain dish, add four [fluid] ounces of Distilled Water and a sufficient quantity of Acetic Acid to neutralise

and dissolve it. Evaporate the solution by the heat of a water-bath until it concretes on cooling. Lastly, dry the salt with a gentle heat, and reduce it to powder." *Br.*

In the U. S. process, morphia is saturated with acetic acid, which is employed in preference to vinegar for saturating the alkaloid, because it can leave no impurity in the resulting salt. The solution of the morphia in the water is an indication that it is saturated. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is required not to employ too much heat in the evaporation; as the acetate is easily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphia. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals; but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphia in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. A less heat is thus required in the evaporation, and impurities in the morphia may often be detected, as they are apt to be insoluble in alcohol. To ascertain, in this case, whether the morphia is saturated, it is necessary to employ litmus paper, the blue colour of which should not be restored, if previously reddened by an acid. If the morphia used in preparing the acetate contain narcotina, it will be best to employ as the solvent distilled vinegar, or diluted acetic acid of the same strength, and to favour its solvent power by heat. Under these circumstances it dissolves only the morphia, leaving the narcotina nearly or quite untouched. (Hodgson, *Journ. of the Philad. Col. of Pharm.*, v. 35.)

The British process differs from that of the U. S. Pharmacopœia only in obtaining uncombined morphia, as the first step, by precipitating it from a solution of the muriate; morphia itself not being among its officinal preparations.

Acetate of morphia crystallizes in the form of slender needles united in fasciculi. It is readily dissolved by water, and less easily by alcohol. As ordinarily obtained, however, by evaporation to dryness, it is not entirely soluble in water, a portion of it being uncombined morphia. To render it soluble, all that is necessary is to add a little distilled vinegar. The U. S. Pharmacopœia gives the following tests of its character. "From its solution potassa throws down a precipitate which is dissolved by an excess of the alkali. It is affected by heat, nitric acid, and sesquichloride of iron, in the same manner as morphia. When sulphuric acid is added to the salt, acetous vapours are evolved." In addition to these tests, the *London College*, in its late Pharmacopœia, referred to the property possessed by this and other salts of morphia, when treated first with chlorine and then with ammonia, of presenting a brown colour, which disappears on the further addition of chlorine. The *Edinburgh College* gave the following mode of testing its purity: "One hundred measures of a solution of ten grains in half a fluidounce of water and five minims of acetic acid, heated nearly to 212°, and decomposed by a faint excess of ammonia, yield by agitation a precipitate which in 24 hours occupies 15·5 measures of the liquid."

From an eighth to a quarter of a grain may be given for a dose, and repeated, if necessary, in order to obtain the anodyne and soporific effects of the medicine. One-sixth of a grain is about equivalent to a grain of opium. It may be given in pill or solution. It is frequently employed externally, sprinkled on blistered surfaces, to obtain its effects upon the system. It is not unfrequently exhibited by subcutaneous injection; but great caution must be observed that it be not thrown into a superficial vein. A case of alarming prostration, coming on after the injection of a third of a grain dissolved in four minims of water into the arm of a woman suffering with neuralgia, is recorded in the *Med. Times and Gaz.* (Jan. 1868, p. 8). Respiration and circulation were apparently suspended; but the patient recovered under active local stimulation, aided by artificial respiration. In the subcutaneous injection of this, as of all other substances given to affect the system, it is important that the solution be perfectly clear.

MORPHIÆ MURIAS. *U.S.* MORPHIÆ HYDROCHLORAS. *Br. Muriate of Morphia. Hydrochlorate of Morphia.*

"Take of Morphia, in fine powder, *a troyounce;* Distilled Water *half a pint;* Muriatic Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water; then carefully drop in Muriatic Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." *U. S.*

"Take of Opium, sliced, *one pound* [avoirdupois]; Chloride of Calcium *three-quarters of an ounce* [avoird.]; Purified Animal Charcoal *a quarter of an ounce* [avoird.]; Diluted Hydrochloric Acid *two fluidounces*, or *a sufficiency;* Solution of Ammonia, Distilled Water, of each, *a sufficiency.* Macerate the Opium for twenty-four hours with two pints [Imperial measure] of the Water, and decant. Macerate the residue for twelve hours with two pints [Imp. meas.] of the Water, decant, and repeat the process with the same quantity of the Water, subjecting the insoluble residue to strong pressure. Unite the liquors, evaporate in a water-bath to the bulk of one pint [Imp. meas.], and strain through calico. Pour in now the Chloride of Calcium previously dissolved in four fluidounces of Distilled Water, and evaporate until the solution is so far concentrated that, upon cooling, it becomes solid. Envelope the mass in a double fold of strong calico, and subject it to powerful pressure, preserving the dark fluid which exudes. Triturate the squeezed cake with about half a pint [Imp. meas.] of boiling Distilled Water, and, the whole being thrown upon a paper filter, wash the residue well with boiling Distilled Water. The filtered fluids having been evaporated as before, cooled, and solidified, again subject the mass to pressure; and, if it be still much coloured, repeat this process a third time, the expressed liquids being always preserved. Dissolve the pressed cake in six fluidounces of boiling Distilled Water; add the Animal Charcoal, and digest for twenty minutes; filter, wash the filter and charcoal with boiling Distilled Water, and to the solution thus obtained add the Solution of Ammonia in slight excess. Let the pure crystalline Morphia which separates as the liquid cools, be collected on a paper filter, and washed with cold Distilled Water until the washings cease to give a precipitate with a solution of nitrate of silver acidulated by nitric acid.

"From the dark liquids expressed in the above process an additional product may be obtained by diluting them with distilled water, precipitating with solution of potash added in considerable excess, filtering, and supersaturating the filtrate with hydrochloric acid. This acid liquid digested with a little animal charcoal, and again filtered, gives upon the addition of ammonia a small quantity of pure morphia.

"Diffuse the pure morphia obtained as above, through two fluidounces of boiling Distilled Water placed in a porcelain capsule kept hot, and add, constantly stirring, the Diluted Hydrochloric Acid, proceeding with caution, so that the morphia may be entirely dissolved, and a neutral solution obtained. Set aside to cool and crystallize. Drain the crystals, and dry them on filtering paper. By further evaporating the mother-liquor, and again cooling, additional crystals are obtained." *Br.*

In relation to the process of the U. S. Pharmacopœia, the remarks made upon the preparation of the sulphate of morphia are equally applicable here. (See *Morphiæ Sulphas.*) The troyounce of morphia, directed in the formula, is not soluble, even when converted into the muriate, in half a pint of cold water; and the process, if exactly followed, could not be carried out. By inadvertence, the direction was omitted to use the water of solution boiling hot, in which condition it will readily dissolve the whole of the muriate produced. The British process is based upon the plan, originally suggested by Wittstock, improved by Dr. Wm. Gregory, and adopted in the Edinburgh Pharmacopœia, of obtaining muriate of morphia immediately from opium without the use of alcohol. The meconate and a little sulphate of morphia extracted by water from opium are de-

composed by chloride of calcium, yielding muriate of morphia in solution, and meconate and sulphate of lime as precipitates. The next step consists in purifying the solution of the muriate by repeated evaporation, crystallization, expression, and re-solution, and finally the action of animal charcoal; the dark expressed liquors being set aside for future operation. The third step in the process is to obtain the morphia separate by precipitation by means of ammonia from the solution of the muriate. Lastly, the crystallized morphia is reconverted, by treatment with muriatic acid and hot water, into the muriate of morphia, which crystallizes from the solution as it cools. The reserved expressed liquors are united, and made to give up their morphia by the reagency of potassa in excess, which at once separates and dissolves the alkaloid. The solution yields it in a crystalline state on the addition of muriatic acid in excess, and afterwards of ammonia. The morphia thus obtained is added to that first procured, and with it again converted into the muriate. Dr. Christison says, in favour of Dr. Gregory's process, that the Edinburgh manufacturers, who follow it, produce a salt of unrivalled purity and cheapness. But it is much better calculated for the large laboratory of the manufacturing chemist, than for the smaller operations of the apothecary, who will probably find the U. S. process more convenient.

Muriate of morphia procured by the old Edinburgh process is free from narcotina; but always contains a portion of muriate of codeia, which, however, is scarcely sufficient to affect its operation upon the system. Dr. Christison found the proportion to vary between a 60th in the muriate prepared from good Turkey opium, a 30th in that from inferior samples of the same variety, and a 12th in that from the East Indian. This impurity may be separated by precipitating the morphia by means of ammonia; the codeia being left in solution; and this no doubt is the object of the last step of the present British process, previously to the final conversion of the morphia into the muriate.

The late Dr. A. T. Thomson published a process for procuring muriate of morphia, which he found considerably more productive than that of the Edinburgh College. After macerating the opium in water, as directed by the College, for thirty hours, and expressing, he rubbed it in a mortar with an equal weight of pure white sand, and enough water to form the mixture into a paste, which he placed in a percolator, and subjected to the action of distilled water till the fluid passed without colour and taste. He then concentrated the liquor to the consistence of a thin syrup, added diacetate of lead, diluted the solution with twice its bulk of distilled water, allowed it to stand for twenty-four hours, decanted the supernatant liquid, washed the precipitate with warm water, added the washings to the decanted solution, and concentrated to one-half. To free the liquid from any remaining acetate of lead, he added diluted sulphuric acid in slight excess, decanted the liquid from the precipitate, washed the latter, added the washings to the solution, and boiled for some minutes to drive off acetic acid. To convert the sulphate of morphia now contained in the solution into muriate, he added a saturated solution of chloride of barium, washed the precipitate, evaporated the conjoined washings and solution to the point of crystallization, pressed the crystals, diluted and again evaporated the mother-liquor so long as it afforded crystals, which were purified by means of animal charcoal, and by repeated solution, evaporation, and crystallization. (*Pharm. Journ.*, i 459.)

Muriate of morphia crystallizes in tufts of feathery acicular crystals. It is white, inodorous, bitter, soluble in 16 parts of water at 60°, and its own weight at 212°, and soluble also in alcohol. A saturated solution in boiling water forms a solid crystalline mass on cooling. The crystals are said to consist of one equivalent of morphia 285, one of muriatic acid 36·5, and six of water 54. Dr. Christison constantly found the crystals, when dried at 150°, to contain 12·7 per cent. of water; and the Edinburgh College stated that the loss of weight at 212° is not above 13 per cent. The salt may be known to be a muriate by yielding in solution, with nitrate of silver, a precipitate insoluble in nitric or muriatic acid, but dissolved by an excess of ammonia. Potassa throws down from its solution a precipitate which is redissolved by an excess of the alkali. The salt is affected

by heat, nitric acid, iodic acid, sesquichloride of iron, and chlorine followed by ammonia, in the same manner as morphia. Sugar is said to have been used largely in the adulteration of this salt. It may be detected by the test of fermentation.

"Twenty grains of the salt dissolved in half a [fluid]ounce of warm water, with ammonia added in the slightest possible excess, give on cooling a crystalline precipitate, which, when washed with a little cold water, and dried by exposure to the air, weighs 15·18 grains." *Br.*

This preparation of morphia is much used in Great Britain, but, in this country, less than either the sulphate or acetate. The dose, equivalent to a grain of opium, is about one-sixth of a grain.

MORPHIÆ SULPHAS. *U.S. Sulphate of Morphia.*

"Take of Morphia, in fine powder, *a troyounce;* Distilled Water *half a pint;* Diluted Sulphuric Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water, then carefully drop in Diluted Sulphuric Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." *U. S.*

In this process the morphia is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphia employed contain narcotina, this will remain in the mother-liquor, and will not contaminate the product. The mother-liquor remaining after the first crystallization, may be evaporated so as to afford a fresh supply of the sulphate; but, if the morphia was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone further preparation. When impure morphia is employed, the mother-liquor should be mixed with alcohol, or boiled with purified animal charcoal and filtered, and then decomposed by ammonia, which will precipitate the morphia. This may be converted into the sulphate in the manner directed by the Pharmacopœia.

Another mode of obtaining sulphate of morphia is to dissolve the alkaloid in boiling alcohol of 36° Baumé (sp. gr. 0·8428), saturate it while hot with sulphuric acid, add purified animal charcoal, boil for a few minutes, and filter the solution at the boiling temperature. Upon cooling, it deposits most of the sulphate; and the remainder may be obtained by evaporating the mother-liquor.

In the evaporation of the solution of this salt, care should be taken not to carry the heat too far; for, when pushed to incipient decomposition with an excess of acid, a new substance is formed containing no morphia.

Sulphate of morphia crystallizes in beautifully white, minute, feathery crystals, which are soluble in twice their weight of cold water, and still more soluble in boiling water. They contain, according to Liebig, in 100 parts, 10·33 of sulphuric acid, 75·38 of morphia, and 14·29 of water. By exposure to a heat of 248° F. they lose 9·66 parts of the water, but cannot be deprived of the remainder without decomposition. They are said to consist of one equivalent of morphia 285, one of sulphuric acid 40, and six of water 54, of which five are water of crystallization, and may be expelled by heat. The tests for it are those for sulphuric acid and for morphia. The dose is from an eighth to a quarter of a grain, which may be given in pill or solution.

MUCILAGINES.

Mucilages.

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U. S. Pharmacopœia, is an aqueous solution of gum, or of substances closely allied to it. In the British Pharmacopœia it is

applied also to the semi-liquid, jelly-like substance, resulting from the cooling of a hot solution of starch. W.

MUCILAGO ACACIÆ. *U. S., Br. Mucilage of Gum Arabic.*

"Take of Gum Arabic, in pieces, *four troyounces;* Water *half a pint.* Add the Water to the Gum Arabic, agitate occasionally until it is dissolved, and strain." *U. S.*

"Take of Gum Acacia, in small pieces, *four ounces* [avoirdupois]; Distilled Water *six fluidounces.* Put the Gum and Water into a covered earthen jar, and stir them frequently until the Gum is dissolved. If necessary, strain the solution through muslin." *Br.*

The gum used for this purpose should be in small fragments, or coarse powder, as it is more readily dissolved in this state than when finely pulverized. Straining is necessary to separate the foreign substances which are often mixed with gum arabic. This mucilage is semi-transparent, almost colourless if prepared from good gum, viscid, tenacious, of a feeble peculiar odour, and nearly tasteless. If the solution of gum should be coloured, it may be rendered colourless by the addition of a concentrated solution of chlorine; and, by boiling for about half an hour so as to drive off the chlorine and muriatic acid, it may be rendered fit for use. (*Guérin.*) By keeping, mucilage becomes sour, in consequence of the spontaneous generation of acetic acid; and this happens even though it be enclosed in well-stopped bottles. But, according to Guérin, the solution of pure gum undergoes no change in vacuo. Heat in its preparation is said to favour the production of acid; and hence cold has been substituted for boiling water in the present formulas. Mucilage is employed chiefly in the formation of pills, and suspending insoluble substances in water. In prescribing it for mixtures, it should be recollected that it is a solution of definite strength, containing, according to the U. S. formula, half an ounce of the gum to each fluidounce of menstruum. The British mucilage is a little stronger. Half a fluidounce is usually sufficient for a six or eight ounce mixture.

MUCILAGO AMYLI. *Br. Mucilage of Starch.*

"Take of Starch *one hundred and twenty grains;* Distilled Water *ten fluidounces.* Triturate the Starch with the Water gradually added; then boil for a few minutes, constantly stirring." *Br.*

This mucilage has an opaline appearance, and gelatinous consistence, and is much used as a vehicle for laudanum and other active medicines given in the form of enema. In consequence of its demulcent properties, it may be usefully employed as an enema in irritation and inflammation of the mucous coat of the rectum and large intestines. Its unpleasant flavour, when it is prepared from ordinary starch, precludes its employment by the mouth.

Off. Prep. Enema Aloes, *Br.;* Enema Magnesiæ Sulphatis, *Br.;* Enema Opii, *Br.;* Enema Terebinthinæ, *Br.* W.

MUCILAGO SASSAFRAS. *U. S.* Infusum Sassafras Medullæ. *U. S.* 1850. *Mucilage of Sassafras. Infusion of Sassafras Pith.*

"Take of Sassafras Pith *one hundred and twenty grains;* Water [cold] *a pint.* Macerate for three hours, and strain." *U. S.*

This infusion may be prepared in a much shorter time, if the pith be broken into small fragments, and the mixture often agitated. It is much used as an application to the eye in inflammation of the conjunctiva. It may be taken as a drink, *ad libitum,* in inflammatory and febrile diseases, particularly inflammations of the mucous passages. W.

MUCILAGO TRAGACANTHÆ. *U. S., Br. Mucilage of Tragacanth.*

"Take of Tragacanth *a troyounce;* Boiling Water *a pint.* Macerate the

Tragacanth with the Water for twenty-four hours, occasionally stirring; then rub them together so as to render the mixture uniform, and strain forcibly through linen." *U. S.*

"Take of Tragacanth, in powder, *sixty grains;* Distilled Water *ten fluidounces.* To the Water contained in a pint bottle add the Tragacanth, agitate briskly for a few minutes, and again at short intervals, until the Tragacanth is perfectly diffused and finally has formed a mucilage." *Br.*

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. From its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. When kept long it is apt to undergo decomposition, and to become offensive. Mr. Maisch has found a paste of tragacanth to keep perfectly well by the addition of enough creasote to impart its characteristic odour faintly. (*Am. Journ. of Pharm.*, March, 1864, p. 97.)

Off. Prep. Trochisci Ferri Subcarbonatis, *U. S.;* Trochisci Ipecacuanhæ, *U. S.;* Trochisci Magnesiæ, *U. S.;* Trochisci Menthæ Piperitæ, *U. S.;* Trochisci Sodæ Bicarbonatis, *U. S.* W.

MUCILAGO ULMI. *U. S.* Infusum Ulmi. *U. S.* 1850. *Mucilage of Slippery Elm Bark. Infusion of Slippery Elm Bark.*

"Take of Slippery Elm Bark, sliced and bruised, *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This may be used *ad libitum* as a demulcent and nutritious drink in catarrhal and nephritic diseases, and in inflammatory affections of the intestinal mucous membrane. It is much employed locally as a demulcent in inflammation of the skin, as in erysipelas, &c. W.

OLEA DESTILLATA.

Distilled Oils.

For an account of the general properties of the volatile or distilled oils, the reader is referred to the head of *Olea Volatilia* in the first part of this work. The following are the U. S. general directions for preparing them.

OLEA DESTILLATA. *U. S.*

"Most of the Distilled Oils are prepared by the following general formula. Put the substance from which the Oil is to be extracted into a retort, or other vessel suitable for distillation, and add enough water to cover it; then distil by a regulated heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."

In this manner are prepared Oil of Anise, from Anise, bruised; Oil of Caraway, from Caraway, bruised; Oil of Cloves, from Cloves, bruised; Oil of Wormseed, from Wormseed; Oil of Cubeb, from Cubeb, bruised; Oil of Canada Fleabane, from Canada Fleabane; Oil of Fennel, from Fennel, bruised; Oil of Gaultheria, from fresh Gaultheria [leaves]; Oil of Hedeoma, from Hedeoma; Oil of Juniper, from Juniper [berries], bruised; Oil of Lavender, from Lavender [flowers]; Oil of Peppermint, from fresh Peppermint; Oil of Spearmint, from fresh Spearmint; Oil of Horsemint, from fresh Horsemint; Oil of Pimento, from Pimento, bruised; Oil of Rosemary, from Rosemary [tops]; Oil of Savine, from Savine, bruised; Oil of Sassafras, from Bark of Sassafras Root, bruised; and Oil of Valerian, from Valerian, bruised.

The *British Council* gives no directions for the preparation of the volatile oils, merely mentioning the names and sources of such as it recognises. The

following general directions of the late Edinburgh Pharmacopœia, published in former editions of the Dispensatory, are retained in the present.

"Substances yielding volatile oils must be distilled with water, the proper proportion of which varies for each article, and for the several qualities of each. In all instances, the quantity must be such as to prevent any of the material from being empyreumatized before the whole oil is carried over. In operations where the material is of a pulpy consistence, other contrivances must be resorted to for the same purpose. These consist chiefly of particular modes of applying heat, so as to maintain a regulated temperature not much above 212°. On the small scale, heat may be thus conveniently applied by means of a bath of a strong solution of muriate of lime, or by means of an oil-bath, kept at a stationary temperature with the aid of a thermometer. On the large scale, heat is often applied by means of steam under regulated pressure. In other operations it is found sufficient to hang the material within the still in a cage or bag of fine net-work; and sometimes the material is not mingled with the water at all, but is subjected to a current of steam passing through it.

"The best mode of collecting the oil is by means of the refrigeratory described in the preface, from which the water and oil drop together into a tall narrow vessel, provided with a lateral tube or lip near the top, and another tube rising from the bottom to about a quarter of an inch below the level of the former. It is evident that, with a receiver of this construction, the water will escape by the lower tube; while the volatile oil, as it accumulates, will be discharged by the upper one, except in the very few instances where the oil is heavier than the water."

Under the general observations on the *Aquæ* or *Waters* (*page* 1029) will be found remarks upon the use of steam in preparing the Distilled Waters, which are to a considerable extent applicable also to the volatile oils.

The substances from which the volatile oils are extracted may be employed either in the recent or dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt, or by means of glycerin, as they afford little or no oil after exsiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh; although it is thought by some that, when moderately dried, they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water till they are thoroughly penetrated by this fluid; and, to facilitate the action of the water, it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising, or other similar mechanical operation.

The water which is put with the subject of distillation into the alembic, answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances it readily rises with the vapour of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 212°; and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 230°. Recourse may also be had to a bath of strong solution of chloride of calcium, or to an oil-bath, the temperature of which is regulated by a thermometer, as suggested by the Edinburgh College in their general directions, given above. Other oils again may be volatilized with water at a temperature below the boiling point; and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a basket, or to place it upon a perforated shelf, in the upper part of the alembic, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object, is to distil it *in vacuo*. Dr. Duncan stated that the most elegant volatile oils he had ever seen were prepared in this manner by Mr. Barry, the

inventor of the process. The employment of steam heat also prevents injury; and the best volatile oils are now prepared in Philadelphia in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of leaden tube, of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end, at which the steam and condensed water escape, passes out laterally below, being furnished with a stop-cock, by which the pressure of the steam may be regulated, and the water drawn off when necessary. In some instances, it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almonds and the oil of mustard. The same method is applicable to the preparation of the distilled waters.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution, when the mixed vapours are condensed; and, if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled; and there will be danger of the substance in the alembic adhering to the sides of the vessel, and thus becoming burnt. Enough water should always be added to cover the solid material, and prevent the latter accident. Dried plants require more water than the fresh and succulent. The whole amount of materials in the alembic should not exceed three-fourths of its capacity; as otherwise there would be danger of the liquor boiling over. The form of the alembic has an influence over the quantity of water distilled, which depends more upon the extent of surface than the amount of liquid submitted to evaporation. By employing a high and narrow vessel, we may obviate the disadvantage of an excess of water. The broad shallow alembic, suitable for the distillation of alcohol and spirituous liquors, will not answer so well in this case. Sometimes the proportion of oil in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the alembic is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant, till the quantity of oil which comes over exceeds its solvent power. This process is called *cohobation.*

The more volatile of the oils pass with facility along with the steam into the neck of the common still; but some which are less volatile are apt to condense in the head, and thus return into the alembic. For the distillation of the latter, a still should be employed with a large and very low head, having a rim or gutter around its internal circumference, into which the oils may be received as they condense, and thence pass into the neck. (See *page* 1031.) As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tube should be straight, than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, become solid by a comparatively slight reduction of temperature; and that, in the distillation of these, the water employed for refrigeration should not be below 42° F.

The mixed vapours are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into the oil and a clear solution of it; the former floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the fluid which comes over has this milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florence receiver* may be used. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end

to bend downwards. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and rising to the top occupies the upper narrow part of the vessel, while the water remains at the bottom, and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates so long as the process continues; but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled. But, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separatory* is usually employed for this purpose. It consists of a glass funnel, bulging at the top, where it is furnished with a stopper, and prolonged at the bottom into a very narrow tube. (See *figure*, *page* 920.) The lower opening being closed, the mixed liquids are introduced and allowed to stand till they separate. The orifice at the bottom is then opened, and, the stopper at the top being a little loosened so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separatory; if lighter, it remains within. Another mode of separating the oil is to introduce into the vessel containing the two liquids one end of a cord of cotton, the other end hanging out, and terminating in a suitable receptacle beneath the level of that immersed in the liquid. The oil at top passes through the cord, and may thus be wholly removed. The last drops may be collected by pressing the cord between the fingers.

The water saturated with oil should be preserved for future distillations; as it can dissolve no more of the oil. One or more volatile acids are frequently found in the distilled water, as the acetic, butyric, or valerianic; and Wunder has detected all three of these acids in the water distilled from chamomile flowers. (*Journ. für Prakt. Chem.*, lxiv. 499.)

According to Overbeck, all the volatile oils may be freed from colouring matter by distilling them from an equal weight of poppy-seed oil, and a saturated solution of common salt. (*Archiv. der Pharm.*, lxxxiv. 149.)

When first procured, the oils have a disagreeable empyreumatic odour, from which they may be freed by allowing them to stand for some days in vessels loosely covered with paper. They should then be introduced into small opaque bottles, which should be well stopped so as to exclude the air. When altered by exposure to air, they may sometimes be restored to their original appearance and quality, by agitation with a little recently heated animal charcoal; and the same method may be employed for freeing them from adhering water.

The volatile oils have the medical properties of the plants from which they are derived; and, as their remedial application has been mentioned under the heads of these plants respectively, it will be unnecessary to treat of it in this place. They may be administered upon a lump of sugar; or triturated with at least ten times their weight of sugar, forming an *oleo-saccharum*, and then dissolved in water; or made into an emulsion with water, sugar, and gum arabic. In making emulsions with volatile oils, it has been recommended first to dissolve them in one of the fixed oils, the oil of almonds for example, and then to emulsionize the oleaginous solution with syrup and gum arabic. For 100 parts of water, 15 of the almond oil in which the volatile oil is to be dissolved, 10 of powdered gum arabic, and 25 of syrup may be taken.* (*Journ. de Pharm.*,

* Prof. Procter has kindly sent us the following suggestions on preparing emulsions of the volatile oils. Oil of turpentine and other volatile oils, to be emulsionized in quantity, are most successfully treated by rubbing them with the powdered gum, and when intimately mixed, adding, at once, with rapid trituration, one and a half times the weight of the gum used of water. By this treatment the volatile oil gets thoroughly divided before contact with water, and, if the quantity of water indicated is added at once, the emulsion has the right preliminary consistence, and unites with and emulsionizes the volatile oil. If, however, but a little water is added, this seizes on the gum, forming a pilular mass, and throws the volatile oil out of union. Such an emulsion is more permanent when a little fixed oil is used, as noted in the text. (*Note to the thirteenth edition.*)

Juin, 1864, p. 461.) The volatile oils are often kept dissolved in alcohol under the name of *essences.** W.

OLEUM ANISI. *U.S., Br. Oil of Anise.*

The British Pharmacopœia refers the oil of anise not only to Pimpinella Anisum, but also to Illicium anisatum.

The product of oil from anise is variously stated from 1·56 to 3·12 per cent. The oil employed in this country is imported. It is colourless or yellowish, with the peculiar odour and taste of the seed. At 50° it crystallizes in flat tables, and does not melt under 62°. Its sp. gr. increases with age, and is variously given from 0·9768 to 0·9903. It is soluble in all proportions in alcohol of 0·806; but alcohol of 0·840 dissolves at 77° only 42 per cent. Ether dissolves it in all proportions. (*Gmelin.*) It consists of two oils, one solid at ordinary temperatures and heavier than water (*stearoptene, anise camphor, solid anethol*), the other liquid and more volatile (*eleoptene, liquid anethol*), both of which are said to have the same atomic constitution, and to consist of carbon, hydrogen, and oxygen ($C_{20}H_{12}O_2$). *Anethol* is a name given to the solid and liquid oils, all having the composition above stated, but differing in properties, which mainly constitute the oils of *anise*, of *star aniseed*, and of *fennel*. (*Gmelin's Handbook*, xiv. 192.) By oxidation, by means of nitric or chromic acid, the different forms of anethol yield a peculiar acid denominated *anisic acid*. (*Ibid.*, xiii. 123.) Oil of anise absorbs oxygen from the air, and becomes less disposed to concrete. In consequence of its high price, it is frequently adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odour. In one instance, as much as 35 per cent. of spermaceti was found. Prof. Procter has met with a parcel, of which not less than five-sixths were alcohol. (*Am. Journ. of Pharm.*, xxvii. 513.) The dose of the oil is from five to fifteen drops. Its comparative mildness adapts it to infantile cases. We are informed that the oil of anise has, in this country, been almost entirely superseded by the *oil of star aniseed* (*oleum badiani*), which closely resembles it in flavour, and which is recognised in the Br. Pharmacopœia under the same name. (See *page* 127.)

Dr. Ruschenberger, of the U. S. Navy, has demonstrated that oil of anise has

* It is often important to know how many drops a volatile oil will yield to the fluidrachm; in other words, the relation of a drop of the oil to a minim. This varies extremely according to the circumstances elsewhere noticed as influencing the size of the drop; so that any results obtained are only approximate and relative. At our request, Professor Procter tried the following oils, with the results stated in the table below. The columns of figures represent the number of drops in a fluidrachm of the oils respectively, the first column giving those obtained by dropping the oils from the bottles in which they are commonly kept, the second by dropping them from a minim measure.

Oleum Anisi	85– 86	Oleum Fœniculi	103–103	Oleum Rosmarini	104–105
" Carui	106–108	" Gaultheriæ	102–101	" Sabinæ	102–108
" Caryophylli	103–103	" Hedeomæ	91– 91	" Sassafras	102–100
" Chenopodii	97–100	" Menthæ Piperitæ	103–109	" Tanaceti	92–111
" Cinnamomi	100–102	" Menthæ Viridis	89– 94	" Valerianæ	116–110
" Cubebæ	86– 96			Creasotum	95– 91

For a table giving results as to the specific gravity, the refracting power, and influence on polarized light, of a large number of volatile oils, prepared by Mr. Gladstone, see the *Journ. de Pharm. et de Chim.* (4e sér., ii. 68, A.D. 1865); also *Am. Journ. of Pharm.* (Sept. 1865, p. 389).

Enfleurage. This term is applied by the French to the impregnation of fixed oils and fatty matters with the odour of certain sweet-scented plants, such as jasmine, tuberose, and mignonette, the oils of which are so delicate and fugitive that they cannot well be separated by distillation. The process consists in exposing the fatty matter, placed in layers, in suitable frames, to the exhalations from the flowers, which are absorbed, and give their characteristic odour to the fat. Another plan is to expose alternate layers of the flowers, and of cotton impregnated with bland fixed oil, to the sun, and afterwards to express the oil from the cotton. For remarks on this process, as conducted in the South of France, see a communication from Mr. Daniel Hanbury in the *London Pharm. Journ.*, copied into the *Am. Journ. of Pharm.* (xxix. 551).—*Note to the eleventh edition.*

the extraordinary property of deodorizing sulphuret of potassium, without undergoing itself any perceptible change; a fluidrachm of anise-water being sufficient completely to change the odour of an ounce of the solution of the sulphuret, depriving it of all offensiveness; and a similar effect was produced by a drop of the oil rubbed up with a drachm of lard, and five grains of the sulphuret. (*Am. Journ. of Med. Sci.*, Oct. 1864, p. 418.)

OLEUM CARI. *U. S.* Oleum Carui. *Br.* *Oil of Caraway.*

"The Oil distilled in Britain from caraway fruit." *Br.*

This oil is prepared to a considerable extent by our distillers. The fresh fruit yields on an average about 4·7 per cent. (*Recluz*); but the product is very variable. The oil of caraway is somewhat viscid, of a pale-yellow colour becoming brownish by age, with the odour of the fruit, and an aromatic acrid taste. Its sp. gr. is differently given at 0·946 (*Baumé*), 0·931 (*Brande*), and 0·916 (*Buignet*). It is dextrogyrate in its relation to polarized light. (Buignet, *Journ. de Pharm.*, Oct. 1861, p. 261.) It consists of two liquid oils, of different boiling points, and separable by distillation; one, a carbohydrogen called *carvene* ($C_{20}H_{16}$, *Völkel*), of the sp. gr. 0·861, and boiling point 343° F.; the other composed of carbon, hydrogen, and oxygen ($C_{20}H_{14}O_2$), and named *carvol*, of the sp. gr. 0·953, and boiling point 482° F. Oil of caraway is much used to impart flavour to medicines, and to correct their nauseating and griping effects. The dose is from one to ten drops.

When oil of caraway is distilled from hydrated phosphoric acid, the distilled liquor being poured back into the retort until it ceases to have the smell of caraway, an oily liquid is obtained, having a very disagreeable odour, and a strong taste. This product, to which the name of *carvacrol* has been applied, has been found to give immediate relief to toothache, when inserted on cotton into the cavity of a carious tooth. (See *Am. Journ. of Med. Sci.*, N. S., xv. 532.)

OLEUM CARYOPHYLLI. *U. S.*, *Br.* *Oil of Cloves.*

"The Oil distilled in Britain from cloves." *Br.*

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition; and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. Professor Scharling has found advantage from the application of super-heated steam to the distillation of this oil. (*Pharm. Journ.*, xi. 469.)* The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies; but, since the introduction of the Cayenne cloves into our markets, the reduced price and superior freshness of the drug have rendered the distillation of oil of cloves profitable in this country; and the best now sold is of domestic extraction. We have been informed that from seven to nine pounds of cloves yield to our distillers about one pound of the oil.

Properties. Oil of cloves, when recently distilled, is very fluid, clear, and colourless, but becomes yellowish by exposure, and ultimately reddish-brown. It has the odour of cloves, and a hot, acrid, aromatic taste. Its sp. gr. is variously stated at from 1·034 to 1·061; the latter being given by Bonastre as the sp. gr. of the rectified oil. It is one of the least volatile of the essential oils, and requires for congelation a temperature from zero of Fahrenheit to —4°.

* For an account of the apparatus employed, and the method pursued by Messrs. Rogers and Crew, of Philadelphia, in the distillation of this oil, see *Am. Journ. of Pharm.*, Jan. 1862, p. 27.

It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its colour to a deep red, and converts it by the aid of heat into oxalic acid. The same change to red is produced by nitric acid on morphia, but in this case the red is followed by yellow, which does not happen with the oil of cloves. Besides, if to a solution of morphia with nitric acid a solution of chlorinated lime be added, and the mixture be exposed for some hours to the light, the solution of morphia will retain a straw colour, while if oil of cloves be treated in the same manner the colour disappears. (Haselden, *B. and F. Med.-chir. Rev.*, July, 1867, p. 265.) When long kept the oil deposits a crystalline *stearoptene*. It is frequently adulterated with fixed oils, and sometimes with oil of pimento and with copaiba. When pure it sinks in distilled water. According to Zeller, its character of congealing entirely into a crystalline mass with the alcoholic solution of potassa, losing at the same time its peculiar odour, affords a sufficient criterion of its purity. It appears to be indifferent in its effects on polarized light, as regards rotary power. (*Buignet.*)

According to Ettling, the oil of cloves consists of two distinct oils, one lighter, the other heavier than water. They may be obtained separate by distilling the oil from a solution of potassa. The lighter comes over, the heavier remains combined with the potassa, from which it may be separated by adding sulphuric acid, and again distilling. *Light oil of cloves* is colourless, has the sp. gr. 0·918, and consists exclusively of carbon and hydrogen, being isomeric with pure oil of turpentine. It is said not to possess active properties. (*Kane.*) *Heavy oil of cloves* is colourless at first, but darkens with age, has the odour and taste of cloves, is of the sp. gr. 1·079, boils at 470°, and forms soluble and crystallizable salts with the alkalies. Hence it has been called *eugenic* or *caryophyllic acid*. It consists of carbon, hydrogen, and oxygen; the formula, according to Ettling, being $C_{24}H_{15}O_5$; according to Gerhardt, who is probably correct, $C_{20}H_{12}O_4$. (*Chem. Gaz.*, no. 373, p. 170.)

Medical Properties and Uses. The medical effects of the oil are similar to those of cloves, and it is used for the same purposes; but its most common employment is as a corrigent of other medicines. Like other powerful irritants, it is sometimes effectual in relieving toothache, when introduced into the cavity of a carious tooth. The dose is from two to six drops.

Off. Prep. Confectio Scammonii, *Br.;* Pilula Colocynthidis Composita, *Br.*

W.

OLEUM CHENOPODII. *U. S.* *Oil of Wormseed.*

This oil is peculiar to the United States. The best is prepared in the vicinity of Baltimore. (See *page* 255.) It is of a light-yellow colour when recently distilled, but becomes deeper yellow and even brownish by age. It has in a high degree the peculiar flavour of the plant. When freshly prepared, it has the sp. gr. 0·908, which, according to Mr. S. S. Garrigues, is increased by time to 0·960. A portion examined by him, which was of a brownish-yellow colour, had the sp. gr. 0·959 at 61° F., boiled at 374°, and was freely soluble in alcohol and ether. He found it to consist of two distinct oils, separable by distillation; one of which consists of carbon and hydrogen exclusively, and reacts with muriatic acid in a manner analogous to oil of turpentine; the other is heavier, and consists of carbon, hydrogen, and oxygen. (*Am. Journ. of Pharm.*, xxvi. 405.) Wormseed oil is used as an anthelmintic, in the dose of from four to eight drops for a child, repeated morning and evening for three or four days, and then followed by a brisk cathartic. The case of a child, six years old, is recorded in the *Boston Med. and Surg. Journ.* (xlv. 373), in which death is supposed to have resulted from the use of overdoses.

W

OLEUM COPAIBÆ. *U.S.*, *Br.* *Oil of Copaiba.*

"The Oil distilled from copaiva." *Br.*

"Take of Copaiba *twelve troyounces;* Water *sixteen pints.* Add the Copaiba to the Water in a tinned still, and, having adapted a proper refrigeratory distil twelve pints. Separate the Oil which comes over from the Water,

return this latter to the still, and again distil twelve pints. Lastly, separate the Oil procured in the second distillation, add it to that first obtained, and keep the whole in a well-stopped bottle." *U. S.*

The oil constitutes from one-third to one-half or more of the copaiba. From one specimen of recent copaiba as much as 80 per cent. has been obtained. (*Am. Journ. of Pharm.*, xxii. 289.) It is prepared largely in Philadelphia by the application of steam heat. As it first comes over it is colourless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colourless. It has the odour and taste of copaiba, boils at about 470° (*Christison*), solidifies, partly crystalline, at —15° F. (*Gmelin*), is soluble in ether and alcohol, absorbs muriatic acid gas, and forms with it crystals of artificial camphor, and when pure consists exclusively of carbon and hydrogen, being isomeric with pure oil of turpentine. From its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Mr. Durand, of Philadelphia. It dissolves sulphur and phosphorus. (*Gmelin's Handbook*, xiv. 288.)

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich, it is one of the least injurious to the animal system of the volatile oils; six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally it produces much less irritation than oil of turpentine. It may be used for the same purposes as copaiba in the dose of ten or fifteen drops, given in emulsion, or simply dropped on sugar. W.

OLEUM CORIANDRI. *Br.* *Oil of Coriander.*

"The Oil distilled in Britain from coriander fruit." *Br.*

This is obtained by distillation with water from the bruised seeds in the manner directed in the U. S. Pharmacopœia for the other volatile oils. Forty-two grains of it are stated by Zeller to be derived from a pound of the fruit. It is pale-yellow and colourless, and has the characteristic smell and taste of coriander. Its sp. gr. is from 0·859 to 0·871; and its boiling point 302° F. It is an oxygenated oil, with the formula $C_{20}H_{18}O_2$. Oil of coriander has the medical properties of the fruit, and, like the aromatic oils generally, may be used to cover the taste, or correct the nauseating or griping properties of other medicines.

Off. Prep. Syrupus Sennæ, *Br.* W.

OLEUM CUBEBÆ. *U.S.*, *Br.* *Oil of Cubeb.* *Oil of Cubebs.*

"The Oil distilled in Britain from cubebs." *Br.*

The oil is obtained from cubebs by grinding them, and then distilling with water. From ten pounds Schönwald procured eleven ounces of oil; and this result very nearly coincides with the experiments of Christison, who obtained 7 per cent. When recently distilled from the fruit, the oil is somewhat greenish, becoming yellowish by age; but when carefully redistilled it is colourless. It has the smell of cubebs, and a warm, aromatic, camphorous taste; is of a consistence approaching that of almond oil; is lighter than water, having the sp. gr. 0·929; and, when exposed to the air, is said to thicken without losing its odour. Upon standing, it sometimes deposits crystals, which are thought to be a hydrate of the oil. It consists of carbon and hydrogen, with the formula $C_{15}H_{12}$.

The oil has the aromatic properties of cubebs; but it is probably not the sole active ingredient; as it is much less pungent than the fluid extract or oleoresin. It may, however, often be advantageously substituted for the powder, in the commencing dose of ten or twelve drops, to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, or in the form of emulsion, or enclosed in capsules of gelatin. W.

OLEUM ERIGERONTIS CANADENSIS. *U.S.* *Oil of Canada Fleabane.*

The oil of fleabane is limpid, of a light-straw colour, a peculiar aromatic persistent odour, and a mild characteristic taste. Its sp. gr., according to Prof. Procter, is 0·845. It probably consists of two distinct oils, as it begins to boil

at 310° F.; and its temperature continues to rise to 365°. When distilled without water, it comes over colourless, and a little resinous matter is left behind, probably resulting from the oxidation of one or both of the constituent oils. It consists of carbon, hydrogen, and oxygen. It is slowly reddened by potassa, combines with iodine without explosion, is instantly decomposed by sulphuric acid, and is acted on by strong nitric acid, slowly at ordinary temperatures, but with heat explosively. (Procter, *Am. Journ. of Pharm.*, xxvi. 502.)

It was first brought into notice by the so-called eclectic physicians, who use it in diarrhœa, dysentery, and the hemorrhages. In a communication by Dr. E. Wilson, of Philadelphia, to the College of Physicians (Nov. 1, 1854), it is stated that the *oil of Philadelphia fleabane* had been employed with great advantage by Dr. Bournonville and himself in uterine hemorrhage. (*Trans. of Col. of Phys.*, N. S., ii. 330.) There can be little doubt, from the account of the oil at the same time given, that it was the oil of *E. Canadense*, or that now under consideration, which was really used; as *E. Philadelphicum* yields merely a trace of volatile oil when distilled; Mr. F. L. John having obtained only half a fluidrachm of it from 45 avoirdupois pounds of the herb. (*Am. Journ. of Pharm.*, xxvii. 105.) Dr. J. W. Moorman, of Hardinburg, Ky., considers, after much experience, the oil of Canada fleabane as a most valuable remedy in all forms of hemorrhage, in diarrhœa of debility, and in dysentery after sufficient evacuation of the stomach and bowels. He reports two cases of copious intestinal hemorrhage in the advanced stage of typhoid fever, in which the discharge was promptly arrested, and life apparently saved by large doses of the oil. In one case he gave two drachms in two doses at an interval of six hours; in the other a drachm and a half in two doses at four hours apart. (*Am. Journ. of Med. Sci.*, Oct. 1865, p. 396.) It probably acts very much like the oil of turpentine as a hæmostatic. For ordinary purposes the dose is from five to ten drops, which should be repeated every hour or two. W.

OLEUM FŒNICULI. *U. S. Oil of Fennel.*

Fennel seeds yield about 2·5 per cent., or, according to Zeller, from 3·4 to 3·8 per cent. of oil. That used in this country is imported. It is colourless or yellowish, with the odour and taste of the seeds. Its sp. gr. is 0·984 to 0·997. It congeals below 50° into a crystalline mass, separable by pressure into a solid and liquid oil (*stearoptene* and *eleoptene*); the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. As found in the shops, therefore, the oil of fennel is not uniform; and a specimen examined by Dr. Montgomery did not congeal at 22°. It consists of carbon, hydrogen, and oxygen; its formula being, according to Blanchet and Sell, $C_{13}H_8O_2$. Its two component oils are now distinguished by the names of *liquid* and *solid anethol*, isomeric with the similar constituents of oil of anise. (See *Oleum Anisi.*) It is slightly dextrogyrate. The dose is from five to fifteen drops.

Off. Prep. Aqua Fœniculi, *U. S.*; Spiritus Juniperi Compositus, *U. S.* W.

OLEUM GAULTHERIÆ. *U. S. Oil of Gaultheria.*

This oil is a product of the United States, and is prepared chiefly in New Jersey. It is directed by the Pharmacopœia to be prepared from the leaves of *Gaultheria procumbens*; but the whole plant is usually employed. It has been obtained by Prof. Procter from the bark of *Betula lenta* or sweet birch, and has been supposed to exist also in the root of *Polygala paucifolia*, and the roots and stems of *Spiræa ulmaria*, *Spiræa lobata*, and *Gaultheria hispidula*, which have its peculiar flavour.

Oil of partridge-berry when freshly distilled is nearly colourless, but as found in the shops has a brownish-yellow or reddish colour. It is of a sweetish, slightly pungent, peculiar taste, and a very agreeable characteristic odour, by which it may be readily distinguished from all other officinal oils. It is the heaviest of the known essential oils, having the sp. gr. 1·173. Its boiling point is 412°. (*Am. Journ. of Pharm.*, iii. 199, and xiv. 213.) Its unusual weight affords a convenient test of its purity. Another distinguishing property is that, in watery solution, it gives a purple colour with the salts of sesquioxide of iron. Prof·

Procter proved it to possess acid properties, and to be closely analogous to *salicylous acid*, one of the results of the decomposition of salicin by sulphuric acid and bichromate of potassa, and an ingredient in oil of *Spiræa ulmaria*. (See *Salix*.) M. Cahours has since corroborated this view, and shown that one-tenth of the oil consists of a peculiar carbohydrogen, which is called *gaultherilen*, and the remaining nine-tenths of *salicylate of oxide of methyl*, or *methylsalicylic acid;* and a product having the properties of the latter compound was obtained by distilling a mixture of pyroxylic spirit, salicylic acid, and sulphuric acid. (*Ibid.*, xiv. 211, and xv. 241.) Methylsalicylic acid forms with bases crystalline salts, which are resolved by heat into salicylic acid and wood spirit. Dr. T. J. Gallaher, of Pittsburg, Pa., records the case of a boy, nine years old, who took about half an ounce of this oil, with the effect of producing severe vomiting, purging, epigastric pain, hot skin, frequent pulse, slow and laboured respiration, dulness of hearing, and, notwithstanding excessive gastric irritability, an uncontrollable desire for food. After two or three days of great danger, he began to improve, and in two weeks was entirely restored to health. (*Med. Examiner*, N. S., viii. 347.) Oil of gaultheria is chiefly used, on account of its pleasant flavour, to cover the taste of other medicines.

Off. Prep. Syrupus Sarsaparillæ Compositus, *U. S.* W.

OLEUM HEDEOMÆ. *U. S.* *Oil of Hedeoma. Oil of American Pennyroyal.*

This, though analogous in properties to the oil of European pennyroyal, is derived from a distinct plant (*Hedeoma pulegioides*) peculiar to North America. It has a light-yellow colour, with the odour and taste of the herb. Its sp. gr. is 0·948. It may be used as a remedy in flatulent colic and sick stomach, to correct the operation of nauseating or griping medicines, and to impart flavour to mixtures. It is also much employed as a domestic remedy in amenorrhœa. The dose is from two to ten drops. W.

OLEUM JUNIPERI. *U. S.*, *Br.* *Oil of Juniper.*

"The Oil distilled in Britain from the unripe fruit of Juniperus communis." *Br.*

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained one per cent. The highest quantity given in the table of Recluz is 2·34, the lowest 0·31 per cent. Zeller gives as the product of the fresh ripe fruit 1·3 per cent., of that a year old 0·86 per cent. (*Cent. Blatt*, März, 1855, p. 207.) The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe, and is believed to be procured chiefly from the tops of the plant, being sold for a price which is altogether incompatible with the idea that it is prepared from the fruit alone. It is colourless, or of a light greenish-yellow, with a terebinthinate odour, and hot acrid taste. Oil of juniper has a sp. gr. from 0·879 to 0·911, and is moderately lævogyrate. (*Buignet.*) It is not very soluble in alcohol. According to Blanchet, it contains two isomeric oils, of which one is colourless, and the other coloured and less volatile. It is, when pure, a carbohydrogen, and is said to have the same composition as oil of turpentine ($C_{10}H_8$); but it does not form a solid compound with muriatic acid. (*Journ. de Pharm.*, xxvi. 80.) Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture, which is considerably less than that of the unadulterated oil of juniper.

The oil is stimulant, carminative, and diuretic; and may be employed advantageously in debilitated dropsical cases, in connection with other medicines, especially digitalis. It is this oil which imparts to Holland gin its peculiar flavour and diuretic power. Sir James Simpson, of Edinburgh, considers it an efficient diuretic when administered through the lungs. A teaspoonful of the oil is put into a vessel of hot water, and the patient directed to inhale the vapours. (*Bost. Med. and Surg. Journ.*, March 12, 1868, p. 96; from *Half-Yearly Compend. of Med. Sci.*) The dose is from five to fifteen drops two or three times a day, and may be considerably increased.

Off. Prep. Spiritus Juniperi, *Br.;* Spiritus Juniperi Compositus, *U. S.* W.

OLEUM LAVANDULÆ. *U. S., Br. Oil of Lavender.*

"The Oil distilled in Britain from the flowers of Lavandula vera." *Br.*

This oil is usually distilled from the flowers and flower-stems conjointly, though of finer quality when obtained from the former exclusively. Dried lavender flowers are said to yield from 1 to 1·5 per cent. of oil. According to Zeller, the fresh flowers yield 1·03, the dried 4·3, the whole fresh herb in flower 0·76 per cent. It is stated that the lavender produced by an acre of ground under cultivation will yield from 10 to 12 pounds of the oil. (*Pharm. Journ.*, Nov. 1864, p. 257.) The oil is very fluid, of a lemon-yellow colour, with the fragrance of the flowers, and an aromatic, burning taste. That met with in commerce has the sp. gr. 0·898 at 68° F., which is reduced to 0·877 by rectification (*Berzelius*), or 0·886 (*Buignet*). It is lævogyrate. According to Brande, the sp. gr. of the oil obtained from the whole herb is 0·9206. Alcohol of 0·830 dissolves oil of lavender in all proportions; that of 0·877, only 42 per cent. (*Berzelius.*) Proust states that, when allowed to stand in imperfectly stopped bottles, it lets fall a crystalline deposit, which often amounts to one-fourth of its weight. This has been found by M. Dumas to have the same point of volatilization and the same composition as the true camphor, but differs in the total want of rotatory power. (*Ibid.*, Juillet, 1863, p. 30.) It is said that the portion of oil first distilled is most fragrant, and is often kept separate, and sold at a higher price. According to M. Lallemand, oil of lavender consists chiefly of an oil isomeric with pure oil of turpentine, but contains acetic acid in combination, probably in the state of amylacetic ether. (*Journ. de Pharm.*, Avril, 1860, p. 290.) It is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of nervous languor and headache. The dose is from one to five drops.*

Oil of Spike is procured from the broad-leaved variety of lavender which grows wild in Europe, the *Lavandula Spica* of De Candolle. Its odour is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes.

Off. Prep. Linimentum Camphoræ Compositum, *Br.;* Spiritus Ammoniæ Aromaticus, *U. S.;* Spiritus Lavandulæ; Spiritus Lavandulæ Compositus, *U. S.;* Tinctura Lavandulæ Composita, *Br.* W.

OLEUM MENTHÆ PIPERITÆ. *U. S., Br. Oil of Peppermint.*

"The Oil distilled in Britain from fresh flowering peppermint, Mentha piperita." *Br.*

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. Zeller gives as the product of the fresh herb from 0·37 to 0·68 per cent., of the dried 1·14 per cent. The yield is generally less than 1 per cent. This oil is largely distilled in the United States. It is of a greenish-yellow colour or nearly colourless, but becomes reddish by age. Its odour is strong and aromatic, its taste warm, camphorous, and very pungent, but succeeded, when air is admitted into the mouth, by a sense of coolness. Its sp. gr. is stated differently from 0·902 to 0·920; its boiling point at 365°. It is considerably lævogyrate. (*Buignet.*) Upon long standing it deposits a *stearoptene*, which, according to Kane, has the same composition as the oil, viz., $C_{21}H_{20}O_2$. Bezelius states that at 8° below zero the oil deposits small capillary

* *Cologne Water.* One of the Farinas, the noted manufacturers of Cologne water, the composition of which has been carefully kept secret by that family, is said recently to have published the following formula, as being that of the genuine perfume. "Take of Oil of Lavender 4 *ounces;* Purified Benzoin, Oil of Rosemary, each, 2 *ounces;* Stronger Alcohol 9 *gallons.* Dissolve the oils and benzoin in the alcohol; and to the solution add successively, of Oil of Neroli, Oil of the young orange denominated by the French Huile de Petits Grains, Oil of Lemons, each, 10·4 *ounces;* Oil of the Sweet Orange, Oil of the Lime, and Oil of Bergamot, each, 20·8 *ounces;* Tincture of the Flowers of the Rose Geranium *a sufficient quantity.* Macerate for some weeks, and introduce into flasks." (See *Am. Journ. of Pharm.*, July, 1864, p. 376.)—*Note to the twelfth edition.*

crystals. These, which are called *peppermint camphor*, melt at 95° F., volatilize unchanged, and, when distilled with anhydrous phosphoric acid, yield a peculiar aromatic product, denominated *menthene*. (*Gmelin's Handbook*, xiv. p. 445.) This oil is frequently adulterated with alcohol, and occasionally, there is reason to believe, with oil of turpentine. This is detected by its odour, by its deficient solubility in cold alcohol, and by imparting the property of exploding with iodine. It is stated by the Messrs. Hotchkiss that, in much of the land under culture with peppermint in this country, other oil-producing plants are carelessly allowed to grow, which, being gathered and distilled with the peppermint, contaminate the product. (*Am. Journ. of Pharm.*, xxvii. 222.) Such impurities may be detected by the altered odour of the oil. When freshly prepared, it should volatilize completely from paper without leaving a mark, and when dropped into alcohol of 85 per cent., should completely dissolve without agitation. (Bullock, *Ibid.*, Nov. 1859, p. 553.) Much of the oil used in the United States is produced in Michigan. (*Ibid.*, xxix. 312.)

Oil of peppermint is stimulating and carminative, and is much used in flatulence, nausea, spasmodic pains of the stomach and bowels, and as a corrigent or adjuvant of other medicines. The dose is from one to three drops, and is most conveniently given rubbed with sugar and then dissolved in water. The oil is frequently employed, dissolved in alcohol, in the form of *essence of peppermint*, which is an officinal preparation. (See *Spiritus Menthæ Piperitæ.*)

Off. Prep. Aqua Menthæ Piperitæ; Essentia Menthæ Piperitæ, *Br.;* Pilulæ Rhei Compositæ; Spiritus Menthæ Piperitæ; Trochisci Menthæ Piperitæ, *U. S.* W.

OLEUM MENTHÆ VIRIDIS. *U. S.*, *Br. Oil of Spearmint.*

"The Oil distilled in Britain from fresh flowering spearmint, Mentha viridis." *Br.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country. It is pale-yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany colour. Its flavour is analogous to that of the oil of peppermint, but less agreeable and less pungent. Its sp. gr. is stated differently from 0·914 to 0·975; its boiling point at 320°. Kane gives the formula $C_{35}H_{28}O$, as representing its composition. It is used for the same purposes as the oil of peppermint, in the dose of from two to five drops. An *essence of spearmint*, prepared by dissolving the oil in alcohol, is officinal. (See *Spiritus Menthæ Viridis.*)

Off. Prep. Aqua Menthæ Viridis; Spiritus Menthæ Viridis, *U. S.* W.

OLEUM MONARDÆ. *U. S.* *Oil of Horsemint.*

This is prepared by our distillers from the fresh herb of *Monarda punctata*. It has a reddish-amber colour, a fragrant odour, and a warm, very pungent taste. At 40° F., or lower, especially in the presence of moisture, it is gradually transformed by oxidation into a crystalline body, having the odour and taste of the oil. This appears to be analogous in constitution to camphor, being the oxide of a carbohydrogen radical ($C_{10}H_7$), three eqs. of which with one eq. of oxygen form the liquid oil. (C. T. Bonsall, *Am. Journ. of Pharm.*, xxv. 200.) It is now considered as identical with thymol, or camphor of the oil of thyme. (See *Oleum Thymi*, in *Part* I.) Applied to the skin, monarda oil is powerfully rubefacient, quickly producing heat, pain, redness, and even vesication. It has been employed externally in low forms of fever, cholera infantum, chronic rheumatism, and other affections in which rubefacients are indicated. In ordinary cases it should be diluted before being applied. It may be given internally as a stimulant and carminative, in the dose of two or three drops mixed with sugar and water. W.

OLEUM ORIGANI. *U. S.* 1850, *Ed.* *Oil of Origanum. Oil of Marjoram.*

This is obtained from the common marjoram, *Origanum vulgare*, and is frequently called *oil of marjoram*. Though it has been satisfactorily determined

by Mr Hanbury that the oil circulating in commerce by the name of oil of origanum is really obtained from *Thymus vulgaris* growing in the south of France, and on this account the proper oil of marjoram has been expunged from our Pharmacopœia, and its place supplied by the oil of thyme (see *Oleum Thymi* in *Part* I.), yet, as Origanum vulgare is a common plant, possessed of valuable aromatic properties, and readily yields its oil by distillation in the ordinary mode, and as there is no reason to suppose that the descriptions given by authors from whom we have quoted are not those of the genuine oil, it is deemed expedient to retain the oil in its old position, and to continue the description given of it in former editions. The plant varies exceedingly in the proportion of oil which it affords. The mean product may be stated at from four to six parts from a thousand. The recent oil, when properly prepared, is yellow; but, if too much heat is used in the distillation, it is said to be reddish, and it acquires the same tint by age. It may be obtained colourless by rectification. It has the odour of the plant, and a hot acrid taste. Kane gives its sp. gr. 0·867, its boiling point 354°, and its composition $C_{50}H_{40}O$. According to Lewis, its sp. gr. is 0·940, according to Brande 0·909. It is sometimes used as an external irritant, and to allay the pain of toothache, by being introduced, on lint or cotton, into the cavity of a carious tooth. It is little employed internally.

The *oil of sweet marjoram* (*Origanum Majorana*) is obtained from the plant by distillation, in the quantity of from 2·5 to 6 parts from 1000. It is of a lemon-yellow colour, light, and camphorous, and is said upon long standing to deposit a substance resembling camphor. It is not used in this country. W.

OLEUM PIMENTÆ. *U. S., Br. Oil of Pimento.*

"The Oil distilled in Britain from pimento." *Br.*

The berries yield from 1 to more than 4 per cent. of oil, which, as found in the shops, is brownish-red, and has the odour and taste of pimento, though warmer and more pungent. It is said, when freshly distilled, to be colourless or yellowish. Nitric acid reddens it. Its sp. gr. is stated at 1·021, but varies. It consists, like oil of cloves, of two distinct oils, a lighter and heavier, the former of which comes over first in distillation. They may be separated by distilling the oil from caustic potassa. The light oil comes over, and the heavy remains combined with the potassa. The latter may be obtained by distilling the residue with sulphuric acid. The light oil is lighter than water, and is a pure carbohydrogen. The heavy has the acid property of forming crystalline compounds with the alkalies. They are analogous to the light and heavy oils of cloves. Indeed, the heavy has been found to be identical with the *eugenic acid* of that oil. (See *Oleum Caryophylli.*) The oil of pimento is given for the same purposes as the other stimulant aromatic oils. The dose is from three to six drops. W.

OLEUM ROSMARINI. *U.S., Br. Oil of Rosemary.*

"The Oil distilled from the flowering tops of Rosmarinus officinalis." *Br.*

The fresh leaves of rosemary yield, according to Baumé, 0·26 per cent. of oil; but the product is stated much higher by others. According to Brande, a pound of the fresh herb yields about a drachm of the oil, which is about 1 per cent.; and Zeller gives very nearly the same product for the dried herb. This oil is colourless, with an odour similar to that of the plant, though less agreeable. Its sp. gr. is said to be 0·911, but reduced to 0·8886 by rectification. Buignet gives the sp. gr. of the rectified oil 0·896, and states that it is moderately dextrogyrate. It is soluble in all proportions in alcohol of 0·830; but requires for solution at 64° forty parts of alcohol of 0·887. (*Berzelius.*) Kane gives its sp. gr. 0·897, its boiling point 365°, and its composition $C_{45}H_{38}O_2$. Kept in bottles imperfectly stopped, it deposits a *stearoptene* analogous to camphor, sometimes amounting, according to Proust, to one-tenth of the oil. Bucholz states that it affords camphor when digested with from one-half its weight to an equal weight of potassa, and distilled. It is said to be sometimes adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol. The oil of rosemary is dissolved, and that of turpentine

left. This oil is stimulant, but is employed chiefly as an ingredient of rubefacient liniments. The dose is from three to six drops.

A case of death is recorded, in a child four or five years old, from a mixture of six measures of this oil, and two of oil of wormseed, given in repeated doses of a tablespoonful. (*Am. Journ. of Pharm.*, xxiii. 286.)

Off. Prep. Linimentum Saponis; Spiritus Lavandulæ Compositus, *U. S.*; Spiritus Rosmarini, *Br.*; Tinctura Lavandulæ Composita, *Br.* W.

OLEUM RUTÆ. *Br. Oil of Rue.*

"The Oil distilled from the fresh herb of Ruta graveolens." *Br.*

Rue yields a very small proportion of a yellow or greenish oil, which becomes brown with age. According to Zeller, the product of the fresh herb is 0·28 per cent., of the seeds about 1 per cent. The oil has the strong unpleasant odour of the plant, and an acrid taste. Kane gives its sp. gr. 0·837, its boiling point 446°, and its composition $C_{28}H_{28}O_3$. Gregory considers it as hydrated oxide of rutyl or rutylic aldehyd ($C_{20}H_{19}O,HO = C_{20}H_{20}O_2$), associated with a carbohydrogen. (*Handbook of Organic Chemistry*, 4th ed., pp. 275 and 342.) According to Williams, the composition of the pure oxygenated oil is $C_{22}H_{22}O_2$, which is confirmed by Harbordt, who, by oxidizing it by means of chromic acid, obtained caprinic acid, and concludes that its proper title is *methylo-caprinol*, and its rational formula $C_2H_3,C_{20}H_{19}O_2$. (See *Am. Journ. of Pharm.*, Jan. 1863, p. 34.) When treated with nitric acid, it yields, among other products, pelargonic acid, which is used in the preparation of a fruit essence, denominated *pelargonic ether*. (See *Fruit Essences*, in *Part* III.) It is stimulant and antispasmodic, and has been given in hysteria, convulsions, and amenorrhœa. The dose is from two to five drops. W.

OLEUM SABINÆ. *U. S., Br. Oil of Savine.*

"The Oil distilled in Britain from fresh savin, Juniperus Sabina." *Br.*

According to the more recent authorities, the proportion of volatile oil obtained from savine varies from less than 1 to 2·5 per cent. The oil is nearly colourless or yellow, limpid, strongly odorous, and of a bitterish, extremely acrid taste. Kane gives its sp. gr. 0·915, its boiling point 315°, and its composition $C_{10}H_8$, equivalent to that of oil of turpentine. According to Winckler, it is converted by sulphuric acid into an oil not distinguishable from that of thyme. (*Chem. Gaz.*, Jan. 1847, p. 11.) With iodine it becomes heated, detonates, and gives off yellow and violet-red vapours. (*Flaschoff.*) Distilled with 24 parts of water and 8 of chloride of lime, it evolves carbonic acid with effervescence, and yields *chloroform*. (*Gmelin's Handbook*, xiv. 310.) The oil of savine is stimulant, emmenagogue, and actively rubefacient, and may be given for the same purposes as the plant in substance. It has been much employed empirically in amenorrhœa, and with a view to produce abortion, and in some instances with fatal effects. The dose is from two to five drops. W.

OLEUM SASSAFRAS. *U. S. Oil of Sassafras.*

The proportion of oil yielded by the root of sassafras is variously stated from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U. S. Pharmacopœia, would afford a larger amount. Very large quantities of the oil are distilled in Maryland, and sent to Baltimore for sale. The usual yield is said by Mr. Sharp to be one pound from three bushels of the root. From fifteen to twenty thousand pounds were sent annually, before the war, to the Baltimore market. (A. P. Sharp, *Am. Journ. of Pharm.*, Jan. 1863, p. 53.) The oil is of a yellow colour or colourless, becoming reddish by age. It has the fragrant odour of sassafras, with a warm, pungent, aromatic taste. It is among the heaviest of the volatile oils, having the sp. gr. 1·094, or 1·087 on the authority of Buignet, who states also that it is very slightly dextrogyrate. At 239° it evaporates freely and boils at 430°. (Procter, *Am. Journ. of Pharm.*, Nov. 1866, p. 491.) According to Bonastre it separates, by agitation with water, into two oils, one lighter, the other heavier than water. Ber-

zelius states that the first is often nothing more than oil of turpentine existing as an adulteration in the oil of sassafras. It is readily soluble in alcohol, ether, and chloroform, and mixes with fixed oils and other volatile oils. (Procter, *Ibid.*) Nitric acid colours it red, and fuming nitric acid inflames it more readily than most other oils. It has the property of dissolving caoutchouc. When kept for a long time it deposits transparent crystals, having the same odour as the liquid oil. By treating the oil with chlorine, neutralizing with lime, and distilling, a product is obtained identical in properties and composition with common camphor. (See *Am. Journ. of Pharm*, xxvi. 166.) Mr. E. S. Wayne, of Cincinnati, has shown that the oil forms an insoluble compound with lead; a property which renders leaden vessels, or those containing lead, unsuitable recipients for it. (*Am. Journ. of Pharm.*, xxviii. 521.) Its composition, according to St. Evre, is represented by the formula $C_{20}H_{10}O_4$. Oil of sassafras is stimulant, carminative, and supposed to be diaphoretic; and may be employed for the same purposes as the bark from which it is derived. The dose is from two to ten drops.

Off. Prep. Syrupus Sarsaparillæ Comp., *U.S.*; Trochisci Cubebæ, *U.S.* W.

OLEUM SUCCINI RECTIFICATUM. *U. S. Rectified Oil of Amber.*

"Take of Oil of Amber *a pint*; Water *six pints*. Mix them in a glass retort, and distil until four pints of water have passed with the Oil into the receiver; then separate the Oil from the Water, and keep it in a well-stopped bottle." *U. S.*

For an account of the crude oil (*Oleum Succini*) the reader is referred to *Part* I. (*page* 614). By successive distillations oil of amber becomes thinner and more limpid, till at length it is obtained colourless. The first portions which distil are less coloured than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled, as directed in the U. S. Pharmacopœia. As usually found in the shops, the rectified oil is of a light yellowish-brown or amber colour. As first distilled it has an amber colour, the sp. gr. 0·903 at 60°, and a boiling point from 339° to 367°. (*Ebert.*) When quite pure it is said to be colourless, as fluid as alcohol, of the sp. gr. 0·758 at 75°, and to boil at 186°. It has a strong, peculiar, unpleasant odour, and a hot, acrid taste. It imparts these properties in some degree to water, without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0·847 at 55°, in five parts of the sp. gr. 0 825, and in all proportions in absolute alcohol, ether, chloroform, bisulphuret of carbon, and the fixed oils. (*Ebert.*) On exposure to light and air, it slowly changes in colour and consistence, becoming ultimately black and solid. It appears, when quite pure, to be a carbohydrogen, consisting, according to Dr. Döpping, of 88·46 parts of carbon and 11·54 of hydrogen in 100. (*Chem. Gaz.*, Nov. 1845, p. 447.) It is said to be sometimes adulterated with oil of turpentine, which may be detected by passing muriatic acid gas through the suspected oil. If pure it will remain wholly liquid; while oil of turpentine, if present, will give rise to the formation of solid artificial camphor. (*Pharm. Journ.*, xiii. 292.)

From a communication, by Mr. A. E. Ebert, in the *Am. Journ. of Pharm.* (March, 1866, p. 146), it appears that there is very little of genuine oil of amber now to be found in the shops; the substances sold as such, being either an oil strongly resembling kerosene, or oil of turpentine holding resin in solution. It would be advisable that the apothecary should either prepare it himself from amber, or obtain it from a chemical manufacturer in whom he could have entire confidence.

Medical Properties and Uses. Rectified oil of amber is stimulant and antispasmodic, and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in amenorrhœa, and in various spasmodic and convulsive affections, as tetanus, epilepsy, hysteria, hooping-cough, and infantile convulsions from intestinal irritation, &c. The dose is from five to fifteen

drops, diffused in some aromatic water by means of sugar and gum arabic. Externally applied the oil is rubefacient, and is considerably employed as a liniment in chronic rheumatism and palsy, and in certain spasmodic disorders, as hooping-cough and infantile convulsions. In the latter affection it should be rubbed along the spine, and was highly recommended by the late Dr. Joseph Parrish, mixed with an equal measure of laudanum, and diluted with three or four parts of olive oil and of brandy. W.

OLEUM TABACI. *U. S. Oil of Tobacco.*

"Take of Tobacco, in coarse powder, *twelve troyounces*. Put it into a retort of green glass, connected with a refrigeratory, to which a tube is attached for the escape of the incondensible products. Then, by means of a sand-bath, heat the retort gradually to dull redness, and maintain it at that temperature until empyreumatic oil ceases to come over. Lastly, separate the dark oily liquid in the receiver from the watery portion, and keep it in a well-stopped bottle." *U. S.*

This is a black, thickish liquid, of a strong characteristic odour, identical with that of old tobacco pipes, and in no degree resembling that of undecomposed tobacco. It may be obtained colourless by rectification, but soon becomes yellowish and ultimately brown. It probably contains a portion of nicotia volatilized unchanged, and is a powerful poison, unfit for internal use, and when employed externally requiring much caution. Mixed with simple ointment or lard, in the proportion of twenty drops to an ounce, it has been used as an application to indolent tumours, buboes, ulcers, and obstinate cutaneous eruptions; but, in all cases where the cuticle is wanting, it should be employed with reserve, and its effects carefully watched. Death has been produced by it in a child, in whom a portion of the oil from the bowl of a tobacco pipe was applied to an ulcer on the lip. (Dr. W. J. Tyrell, *Med. and Surg. Reporter*, May 2, 1868, p. 384.) W.

OLEUM VALERIANÆ. *U. S. Oil of Valerian.*

This was introduced for the first time as an officinal into the U. S. Pharmacopœia of 1850. It is obtained from the root of Valeriana officinalis by the usual process of distillation with water. According to Zeller, the dried root of the best quality yields 1·64 per cent. of the oil. Very good oil has been distilled from the root cultivated in this country. As first procured, it is of a pale-greenish colour, of the sp. gr. 0·934, with a pungent odour of valerian, and an aromatic taste. Upon exposure, it becomes yellow and viscid. It is a complex substance, containing 1. a carbohydrogen isomeric with pure oil of turpentine; 2. a small proportion of stearoptene, of an odour resembling that of camphor and pepper, and formed probably by the combination of water with the preceding constituent; 3. a peculiar oxygenated oil, called *valerol* ($C_{20}H_{12}O$, Kane's *Chemistry*), which, by the agency of the air, is converted into *valerianic* (*valeric*) *acid* and a resinous matter; and 4. valerianic acid, which always exists in the oil in small proportion, but is increased by exposure. The conversion of valerol into valerianic acid, through the agency of atmospheric oxygen, is very much promoted by the presence of caustic alkalies, which combine with the acid, when formed, to produce valerianates. Somewhat different views of the oil are given by M. Pierlot, who has investigated its nature. According to this chemist, the oil, whether fresh or old, always contains about 5 hundredths of valerianic acid, and, besides this, the two oils above referred to, namely, the carbohydrogen, which he names *valerene*, and the valerol, the formula of which he gives as $C_{21}H_{20}O_2$, and which becomes resinified by exposure to the air. He has concluded, moreover, that valerol cannot be changed into an acid by any known process. (See *Am. Journ of Pharm.*, March, 1860, p. 142.) The oil of valerian exercises the same influence as the root on the nervous system, and is frequently administered as a substitute for it in the dose of four or five drops. W.

OLEORESINÆ.

Oleoresins.

The oleoresins, as a class of Preparations, were newly introduced into the U. S. Pharmacopœia at the late revision, having been previously considered with the Fluid Extracts. Their peculiarity is that they consist of principles, which, when extracted by means of ether, retain a liquid or semi-liquid state upon the evaporation of the menstruum, and at the same time have the property of self-preservation; differing in this respect from the fluid extracts, which require the presence of alcohol or sugar to prevent decomposition. They consist chiefly, as their name implies, of oil either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhaustion of the medicine employed with ether, by means of percolation, and the subsequent evaporation of the menstruum. In consequence of the great volatility of ether, it may in great measure be recovered by distillation, thus very materially diminishing the costliness of the process. It is proper not to continue the heat necessary for the distillation till the whole of the ether is driven over, lest, towards the close, a portion of the volatile matters also should pass, and the strength of the oleoresin be impaired. Hence, in every instance, the last portions of the menstruum are allowed to separate by spontaneous evaporation. Benzine has been proposed as a substitute for ether in these preparations, but should not be permitted to supersede it until officinally sanctioned. W.

OLEORESINA CAPSICI. *U. S.* *Oleoresin of Capsicum.*

"Take of Capsicum, in fine powder, *twelve troyounces;* Ether *a sufficient quantity.* Put the Capsicum into a cylindrical percolator, press it firmly, and gradually pour Ether upon it until twenty-four fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether, and expose the residue, in a capsule, until the remaining ether has evaporated. Lastly, remove, by straining, the fatty matter which separates on standing, and keep the Oleoresin in a well-stopped bottle." *U. S.*

The active principle of capsicum, called capsicin, is very soluble in ether, and is wholly extracted in the process. Its precise nature has not been determined; but, in the purest form in which it has been obtained, it is of a semi-liquid oleaginous consistence. After the concentration of the ethereal solution, a solid fatty matter separates on standing, but a portion of fixed oil probably still remains. The preparation is a very thick liquid, capable, however, of being dropped, of a dark reddish-brown colour, and, though opaque in mass, yet transparent in thin layers. It has not very decidedly the odour of capsicum, but to the taste is intensely pungent. It may be usefully employed to give locally stimulant properties to substances administered internally in a pilular form, in cases of gastric insensibility and excessive flatulence. Not more than a drop should be given at once, and that very much diluted, whether mixed with solids in the pill mass, or in liquid mixtures. It may be used also as a powerful rubefacient, diluted with olive oil or soap liniment. W.

OLEORESINA CUBEBÆ. *U. S.* EXTRACTUM CUBEBÆ FLUIDUM. *U. S.* 1850. *Oleoresin of Cubeb. Fluid Extract of Cubebs.*

"Take of Cubeb, in fine powder, *twelve troyounces;* Ether *a sufficient quantity.* Put the Cubeb into a cylindrical percolator, press it moderately, and gradually pour Ether upon it until twenty-four fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether, and expose the residue, in a capsule, until the remaining ether has evaporated. Lastly, keep the Oleoresin in a well-stopped bottle." *U. S.*

This *oleoresin* consists mainly of the volatile oil and resin, with a portion of the cubebin and waxy matter of the cubebs. The consistence differs with

the character of the cubebs employed; its degree of fluidity being proportionate to the amount of volatile oil contained in the medicine. The colour is usually blackish-brown, with more or less of a greenish hue, according to the quantity of chlorophyll present, which varies with the character of the cubebs, and with that of the menstruum; pure ether extracting the green colouring matter preferably, while ordinary alcoholic ether extracts also the brown. Cubebs yield from one-eighth to one-fifth of their weight of fluid extract. The preparation deposits waxy matter and crystals of cubebin on standing; but its efficacy is probably not impaired. It was first introduced into use by Prof. Procter. (*Am. Journ. of Pharm.*, xviii. 168.)

From carefully conducted experiments by Mr. F. V. Heydenreich, it would appear that, of the various constituents of cubebs contained in the officinal oleoresin, the cubebin has no perceptible effect in the dose of the medicine ordinarily given, that the volatile oil is simply stimulant and carminative, and, finally, that the soft resin has all the diuretic properties of the cubebs. Of the last-mentioned ingredient, twenty grains given every two hours till five doses were taken, considerably increased the secretion of urine, producing at the same time a slight burning sensation in the passage, which ceased with the diuretic action. Pushed beyond this amount, it occasioned severe irritation of the urinary passages, with some fever. (*Ibid.*, Jan. 1868, p. 42.)

Prof. Procter has noticed that this oleoresin, as it occurs in the market, often has a decided ethereal odour, is of a thin consistence, and occasionally exhibits crystals of cubebin, either floating in the liquid, or adhering to the sides of the bottle. In one specimen three-eighths of its weight of ether were lost, in a short time, by spontaneous evaporation. He thinks that the quantity of ether employed in the process is unnecessarily large. As the cubebs are very nearly exhausted by the ether before the whole of it has passed, there is a considerable expenditure of that liquid for the sake of a scarcely appreciable portion of the active matter. In all cases of excess of ether in the oleoresin, the pharmaceutist should allow it to escape by spontaneous evaporation in a capsule. (*Ibid.*, May, 1860, p. 210.)

The dose of this oleoresin is from five to thirty minims, which may be given suspended in water, or mixed with powdered sugar.

Off. Prep. Troschisci Cubebæ, *U. S.* W.

OLEORESINA FILICIS. Extractum Filicis Liquidum. *Br. Oleoresin of Male Fern. Liquid Extract of Fern Root.*

"Take of Male Fern, in coarse powder, *two pounds* [avoirdupois]; Ether *four pints* [Imperial measure], or *a sufficiency*. Pack the Male Fern closely in a percolator; and pass the Ether slowly through it, until it passes colourless. Let the ether evaporate on a water-bath, or recover it by distillation, and preserve the oily extract." *Br.*

This is a new officinal of the British Pharmacopœia, and ought to have a place in our own. Though introduced in the Pharmacopœia among the Extracts, it yet by its character belongs so decidedly to the oleoresins, that we have deemed it expedient to give it this position, and to name it, in chief, *Oleoresin of Male Fern*. It is an ethereal extract of the fern root, consisting mainly of oily and resinous matter, and has been long known and much used on the Continent of Europe, under the name of *oil of fern*, in the treatment of the tapeworm. It is a thick, dark liquid, with the odour of fern, and a nauseous, bitterish, somewhat acrid taste. (See *Filix Mas*, in *Part* I.) It is believed to have all the anthelmintic powers of the male fern, and may be given in the dose of half a fluidrachm. W.

OLEORESINA LUPULINÆ. *U. S. Oleoresin of Lupulin.*

"Take of Lupulin *twelve troyounces;* Ether *a sufficient quantity*. Put the Lupulin into a narrow cylindrical percolator, press it firmly, and gradually pour Ether upon it until thirty fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether.

and expose the residue, in a capsule, until the remaining ether has evaporated. Lastly, keep the Oleoresin in a wide-mouthed bottle, well stopped." *U. S.*

Lupulin yields its volatile oil and resin, as well as any other active principle it may contain, to ether, and the resulting oleoresin constitutes about three-eighths, or somewhat less than one-half of the original drug. It is of a very thick semi-fluid consistence, so thick indeed that it cannot be conveniently administered by drops. Its colour is almost black in mass, but a rich reddish-brown in thin layers. It has the odour and taste of lupulin, and possesses all its medical properties. The dose is from two to five grains, and may be most conveniently administered in the form of pill, made with powdered liquorice root, or other proper excipient. W.

OLEORESINA PIPERIS. *U. S.* Extractum Piperis Fluidum. *U. S.* 1850. *Oleoresin of Black Pepper. Fluid Extract of Black Pepper.*

"Take of Black Pepper, in fine powder, *twelve troyounces;* Ether *a sufficient quantity.* Put the Black Pepper into a cylindrical percolator, press it firmly, and gradually pour Ether upon it until twenty-four fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether, and expose the residue, in a capsule, until the remaining ether has evaporated, and the deposition of piperin in crystals has ceased. Lastly, separate the Oleoresin from the piperin by expression through a muslin strainer, and keep it in a well-stopped bottle." *U. S.*

A substance has long been in use under the name of *oil of black pepper*, consisting mainly of the volatile oil, fixed oil, and resin of the pepper, and belonging, therefore, to the oleoresins. As usually found, it is almost black, and of a thickish consistence, and is a residue of the process for preparing piperin. The officinal oleoresin has the same general character, but is more fluid, and of more uniform strength, and should, therefore, be preferred. It contains almost all the volatile oil and acrid resin of black pepper, with little of the piperin; and, as the last-mentioned principle, when quite pure, is of doubtful efficacy, the extract may be considered as representing the virtues of the fruit. The colour is greener than that of the common oil of black pepper, and not so dark, owing to the fact that ether dissolves the green more readily than the brown colouring matter. A pound of black pepper yields about six drachms of the fluid extract, the dose of which, proportionate to the ordinary dose of pepper, would be one or two minims. It may be given in emulsion, or may be combined in small proportion with other substances in the form of pill. W.

OLEORESINA ZINGIBERIS. *U. S. Oleoresin of Ginger.*

"Take of Ginger, in fine powder, *twelve troyounces;* Stronger Ether *twelve fluidounces;* Alcohol *a sufficient quantity.* Put the Ginger into a cylindrical percolator, press it firmly, and pour upon it the Stronger Ether. When this has been absorbed by the powder, add Alcohol until twelve fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, nine fluidounces of ether, and expose the residue, in a capsule, until the volatile part has evaporated. Lastly, keep the Oleoresin in a well-stopped bottle." *U. S.*

In the preparation of this oleoresin alcohol is used in connection with ether, but solely on the score of economy; as it is added in order to displace the ether, and thus save an unnecessary expenditure of this more costly fluid. A little of the alcohol, no doubt, mixes with the ether at their surface of contact, but only a little; and the liquid which passes is mainly the ether loaded with the oleoresinous matter of the ginger. The whole of the virtues of the root are extracted in this preparation, as the residuary ginger is nearly or quite tasteless. The oleoresin constitutes about 5 per cent. of the dried root. It is the *piperoid of ginger* of M. Beral. (*Soubeiran's Trait. de Pharm.*, i. 371.) It is a clear, dark-brown liquid, of a thick consistence, though capable of being dropped, with the flavour of ginger, and intensely pungent. Its dose should not exceed a minim, and should be much diluted when administered. W.

PILULÆ.

Pills.

These are small globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and do not require to be given in large doses. Deliquescent substances should not be made into pills; and those which are efflorescent should be previously deprived of their water of crystallization. Care should also be taken not to combine materials, the mutual reaction of which may result in a change of form.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins; and the addition of a little water to the former, and a few drops of spirit to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as wheat flour, starch, and powdered gum arabic, or with crumb of bread. Powders must be mixed with soft, solid bodies, as extracts, confections, soap, &c., or with tenacious liquids, as syrup, molasses, honey, mucilage, or glycerin; and the last-mentioned substance has been especially recommended in connection with a little alcohol. (*Tichborne.*) Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used; but pills made with it are apt when kept to become hard, and of difficult solubility in the liquids of the stomach, and, if metallic substances are mixed with it, the mass does not work well. A mixture of syrup and powdered gum arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Honey has been highly recommended. Confection of roses and molasses are among the best excipients, when the pills are to be long kept. For the same purpose of keeping the pill soft, the addition of a small portion of some fixed oil or deliquescent salt has been recommended; and glycerin will probably answer still better. Many powders require only water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with that liquid. Care should always be taken that the matter added be not incompatible with the main constituents of the pill.

The materials should be accurately mixed together, and beat in a mortar till formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric liquors. As pills frequently become very hard by time, it is often convenient to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in bladders, putting it in covered pots, and occasionally moistening it as it becomes dry; or, more effectually, by keeping it in glass or well-glazed jars, accurately closed with varnished bladder.

The mass, having been duly prepared, is made into pills by rolling it with a spatula, or with a flat, smooth piece of hard wood, into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or more accurately by a machine made for the purpose.* The pills receive a spherical form by being rolled between the fingers. M. Mialhe describes a little instrument for rolling

* The common pill-machine is too well known to require description. In the *Am. Journ. of Pharm.* (xxiv. 315) the reader will find the description of a rotary pill-machine, calculated to prepare large numbers of pills in a short time; and in the same journal (xxvi. 118) of another, which is considered an improvement on the first. Perhaps the machine which combines the greatest number of advantages is that known as *Busby's pill-machine*, which the reader will find described and figured in the *Am. Journ. of Pharm.* for Jan. 1869, and which is almost enthusiastically commended by the editor of the *Lond. Chem. and Druggist* in the number of that journal for Nov. 1868. (*Note to the thirteenth edition.*)

pills, composed of two circular plates, one about 12, the other 6 inches in diameter; the former having a ledge at the border one-third of an inch high, the latter with a similar ledge, varying, according to the size of the pills, from less than a line to nearly two lines, and with a strap on the back by which it can be fitted to the hand. This is to be moved in a rotary manner upon the larger plate, holding the divided portions of the pill mass. (*Journ. de Pharm.*, 3e sér., xvii. 218.) In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose carbonate of magnesia, powdered liquorice root, or starch may be used. Carbonate of magnesia is sometimes incompatible with one of the ingredients of the pills; and liquorice root is generally preferable, though it sometimes becomes mouldy with very damp pills. The powder of *lycopodium*, which has been long in use in Europe, is now considerably employed in this country, and is perhaps the best substance for the purpose; and it was formerly the custom to give the pill a coating of gold or silver leaf.*

It has been proposed by M. Garot to cover pills with gelatin, which answers the purpose of concealing their taste and odour, and counteracting deliquescence or chemical change from exposure to the air, without interfering with their solubility in the stomach. He dips each pill, sustained on the point of a pin, into melted gelatin, withdraws it with a rotary motion, then fixes the pin in a paste so as to allow the coating to dry in the air, and, having prepared about fifty pills in this way, proceeds to complete the operation by holding the pin in the flame of a taper so as to melt the gelatin near its point, and then withdrawing it from the pill so as to close up the orifice. The purest glue should be selected for this purpose, melted with the addition of two or three drachms of water to an ounce of the glue, and kept liquid by means of a salt-bath.

Another plan for attaining the same objects, less effectual, but more convenient than the above, is to introduce the pills into a spherical box, to drop on them enough syrup simply to moisten their surface, then to give a rotary movement to the box until the pills are uniformly covered, and finally to add by degrees a powder consisting of equal parts of gum, sugar, and starch, shaking the box with each addition, and continuing the process until nothing more will adhere to the pills. The investing material may be rendered agreeable to the taste and smell by aromatic additions, if deemed advisable. (*Journ. de Pharm.*, x. 32.) M. Calloud has found that a better powder for the purpose, because less disposed to attract moisture, is made by boiling one part of flaxseed and three parts of white sugar with sufficient water till a thick mucilage is formed, evaporating this carefully to dryness, and then pulverizing. (*Ibid.*, xxiii. 301.) The same writer has since suggested, as still more effective, a powder made by forming a mucilage with one part of tragacanth and two of water, pressing this through linen, mixing it with twenty parts of sugar of milk, spreading the paste thus made in thin layers to dry, and then powdering. The pills may be simply moistened with water, and then shaken in the powder. M. Lhermite proposes first to agitate the pills in a mortar with a little concentrated solution of gum, and afterwards to put them into a box containing dry and very finely powdered sugar, to which a rotary motion is given. If the coating be not sufficiently thick, the process may be repeated. (*Ibid.*, xxv. 460.)† Still another

* This mode of protecting pills is still practised to some extent; and Messrs. Parrish and Bakes have published their method of proceeding. It consists in agitating the pills, prepared without dusting powder, and with their surface still damp, along with gold or silver leaf, in a hollow spherical wooden box, made by turning two hemispheres out of hard wood, fitting each other, and provided with a short handle. (*Am. Journ. of Pharm.*, Jan. 1861, p. 2.)

† The sugar coating of pills is now conducted upon a great scale by manufacturers, who send large quantities both of popular and officinal pills into the market thus protected The process employed is similar to that of the confectioners in coating almonds. After having been thoroughly dried, the pills are put into a hemispherical tinned copper basin, which is suspended from the ceiling, and moved quickly backward and forward with an

method, proposed by Mr. E. K. Durden, is to cover the pills with collodion, which completely conceals the taste. The solution employed by Mr. Durden had the sp. gr. 0·810; and two dippings give a sufficient coating. (See *Am. Journ. of Pharm.*, xxi. 183.) It is, however, yet to be determined whether a coating of collodion would yield readily to the solvent powers of the gastric juice. M. Blancard covers pills with a solution of Tolu balsam in ether; but Mr. H. C. Baildon objects to this, that it takes too long to dry, and suggests as a substitute a solution of a drachm of the balsam in three drachms of chloroform, which dries sufficiently in twenty minutes. (*Am. Journ. of Pharm.*, xxix. 350.) If old and solid Tolu balsam be selected, it will be less liable to the objection of drying slowly. This balsam is officinally employed in coating the U. S. pills of iodide of iron. A solution of mastic in ether has also been used for coating pills; and the white of egg has been recommended for the same purpose. (*Ibid.*, March, 1862, p. 137.)

Pills which are to be long kept should be well dried, and put into bottles with accurately fitting stoppers. Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills; yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass, when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to retain a portion of the mass undivided, especially when it is desirable to keep the pills soft.*

eccentric motion, so as to cause a constant attrition among the pills. First a little very thick syrup, or syrup of gum, is introduced in order to give a thin coating to their surface; and afterwards very finely powdered and very dry white sugar is sifted or thrown over them; the motion being constantly maintained. The sugar is fixed by the moist surface of the pills, and the coating made compact and smooth by the attrition. The process is aided by a gentle heat, arising from an open charcoal fire beneath; but the heat must be guarded, lest the pills be much softened, and thus lose their shape, and even discolour the coating. Dextrous manipulation is necessary in order that the process may succeed satisfactorily. For practical remarks on the sugar-coating of pills, see an essay by Mr. H. C. Archibald in the *Am. Journ. of Pharm.* for May, 1867, p. 199. (*Note to the twelfth and thirteenth editions.*)

Mr. Edward Parrish has published a proceeding, hitherto kept more or less secret, for the manufacturing of pills on a large scale, which we take from the *Am. Journ. of Pharm.* (Jan. 1867, p. 12), in a somewhat condensed form. Sugar, having been granulated, is separated into granules of different sizes, so as to have uniformity in this respect. A clean copper pan is now suspended by a cord two or three feet above a charcoal fire in a small furnace. Into this the granules are introduced, and, having been moistened with a thick mucilage or syrup, are then dusted over with the ingredients of the pills, reduced to fine powder and thoroughly mixed. By a rapid rotary and shaking motion of the pan, the powder is equally diffused over the moistened granules; and the process of moistening and application of the dry powder, with rotation, is repeated more or less frequently, till at length pills are formed nearly equal in size, and perfectly round. The smaller are now separated by a sieve from those of the desired size; and the former are returned to the pan to undergo a further treatment of the same kind. Those which may be too large are dried and powdered, and undergo the same treatment. The chief art in making the pills by this method consists in a proper regulation of the heat and dextrous manipulation. The pan should not be allowed to become hot, and should be held by the left hand which moves it, while the right hand is used to prevent the pills from adhering, and in aiding the rotary movement. This plan is adapted to preparing pills on the large scale, and is not equally applicable to all. (*Am. Journ. of Pharm.*, Jan. 1867, p. 12.)—*Note to the thirteenth edition.*

* *Granules.* Minute pills, scarcely larger than a pin's head, have for some years been popular in France, under the name of granules; and their use has been introduced into the United States, where they are now largely consumed. They are generally used for the administration of very powerful medicines, as digitaline for instance, which is given in the dose of one-fiftieth of a grain. An objection to them is the great difficulty of securing an exactly equal amount of the medicine in each granule; and great care, therefore, is necessary, in their preparation, to guard against this danger. Like the pills these also are prepared on the large scale, and like them are sugar-coated. The process moreover for making them is somewhat similar. The mass is first divided by a hand machine so as to ensure uniformity of size, and the little particles are then coated. The details, however, of the proceeding, as well as of the apparatus employed, are kept secret. (*Note to the twelfth edition.*)

The Pills formerly officinal, which have been omitted in the present U. S. and Br. Pharmacopœias, are the *Compound Pills of Aloes*, Lond., Dub.; the *Pills of Calomel and Opium*, Ed.; the *Pills of Sulphate of Iron*, Ed.; those of *Mild Chloride of Mercury*, U. S.; the *Opiate Pills of Lead*, Ed.; *Pills of Rhubarb and Iron*, Ed.; and the *Compound Pills of Storax*, Lond., Ed. W.

PILULÆ ALOËS. *U. S.* Pilula Aloes Barbadensis. *Br.* Pilula Aloes Socotrinæ. *Br.* *Pills of Aloes. Pill of Barbadoes Aloes. Pill of Socotrine Aloes.*

"Take of Socotrine Aloes, in fine powder, Soap, in fine powder, each, *a troyounce.* Beat them together with water so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Barbadoes Aloes, in powder, *two ounces* [avoirdupois]; Hard Soap, in powder, *one ounce* [avoird.]; Oil of Caraway *one fluidrachm;* Confection of Roses *one ounce* [avoird.]. Beat all together until thoroughly mixed." *Br.*

The British process for pill of Socotrine Aloes is the same, except that Socotrine is substituted for Barbadoes Aloes, and the volatile Oil of Nutmeg for that of Caraway.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation, and diminish its liability to irritate the rectum. Five of the U. S. pills, containing ten grains of aloes, may be given with a view to their purgative effect; but the preparation is usually employed as a laxative in habitual costiveness, in the quantity of one, two, or three pills, taken before breakfast or dinner, or at bedtime. The British pill is of very nearly the same strength. W.

PILULÆ ALOËS ET ASSAFŒTIDÆ. *U. S., Br.* *Pills of Aloes and Assafetida.*

"Take of Socotrine Aloes, in fine powder, Assafetida, Soap, in fine powder, each, *half a troyounce.* Beat them together with water so as to form a pilular mass, to be divided into one hundred and eighty pills." *U. S.*

"Take of Socotrine Aloes, in powder, Assafetida, Hard Soap, in powder, Confection of Roses, of each, *an ounce.* Beat all together until thoroughly mixed." *Br.*

These pills are peculiarly adapted, by the stimulant and carminative properties of the assafetida, to cases of costiveness attended with flatulence and debility of the digestive organs. Each pill contains about four grains of the mass. From two to five may be given for a dose. W.

PILULA ALOES ET FERRI. *Br.* *Pill of Aloes and Iron.*

"Take of Sulphate of Iron *one ounce and a half;* Barbadoes Aloes, in powder, *two ounces;* Compound Powder of Cinnamon *three ounces;* Confection of Roses *four ounces.* Reduce the Sulphate of Iron to powder, rub it with the Aloes and Compound Powder of Cinnamon, and adding the Confection make the whole into a uniform mass." *Br.*

This is essentially an old preparation of the Edinburgh Pharmacopœia, which, having been omitted in the original British, has been resumed in the present edition. It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished by combination with sulphate of iron. This pill is especially adapted to amenorrhœa with debility of the stomach and constipation. The dose is from five to ten grains. W.

PILULÆ ALOËS ET MASTICHES. *U. S.* *Pills of Aloes and Mastic.*

"Take of Socotrine Aloes, in fine powder, *a troyounce and a half;* Mastic, in fine powder, Red Rose, in fine powder, each, *half a troyounce.* Beat them together with water so as to form a pilular mass, to be divided into four hundred pills." *U. S.*

Each of these pills contains about four grains of the mass, including the water employed, and nearly two grains of aloes. They are an imitation of

Lady Webster's dinner pills, and one of them may be given as a laxative at bedtime, or before a meal. The mastic has probably little other effect than to impair the solubility of the aloes, and thus give it a still greater tendency to act on the lower bowels.* W.

PILULÆ ALOËS ET MYRRHÆ. *U. S.*, *Br.* *Pills of Aloes and Myrrh.*

"Take of Socotrine Aloes, in fine powder, *two troyounces;* Myrrh, in fine powder, *a troyounce;* Saffron, in fine powder, *half a troyounce;* Syrup *a sufficient quantity.* Beat the whole together so as to form a pilular mass, to be divided into four hundred and eighty pills." *U. S.*

"Take of Socotrine Aloes *two ounces;* Myrrh *one ounce;* Saffron, dried, *half an ounce;* Confection of Roses *two ounces and a half.* Triturate the Aloes, Myrrh, and Saffron together, and sift; then add the Confection of Roses, and beat them together into a uniform mass." *Br.*

This composition has been long in use, under the name of *Rufus's pills.* It is employed, as a warm stimulant cathartic, in general debility attended with constipation, and retention or suppression of the menses. From three to six pills, or from ten to twenty grains of the mass may be given for a dose. W.

PILULÆ ANTIMONII COMPOSITÆ. *U.S.* PILULA HYDRARGYRI SUBCHLORIDI COMPOSITA. *Br.* PILULA CALOMELANOS COMPOSITA. *Br.* 1864. *Compound Pills of Antimony. Compound Pill of Subchloride of Mercury. Compound Calomel Pill. Plummer's Pills.*

"Take of Sulphurated Antimony, Mild Chloride of Mercury, each, *one hundred and twenty grains;* Guaiac, in fine powder, Molasses, each, *half a troyounce.* Rub the Sulphurated Antimony first with the Mild Chloride of Mercury, and afterwards with the Guaiac and Molasses, so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Subchloride of Mercury, Sulphurated Antimony, of each, *one ounce* [avoirdupois]; Guaiacum Resin, in powder, *two ounces* [avoird.]; Castor Oil *one fluidounce*, or *a sufficiency.* Triturate the Subchloride of Mercury with the Antimony, then add the Guaiacum Resin and Castor Oil, and beat the whole into a uniform mass." *Br.*

We prefer the title "compound calomel pill" of the former British Pharmacopœia; as, though not scientific, it is not liable to any mistake, and is most expressive of the quality of the medicine. The antimonial employed, though under a different name, is identical with the old U. S. precipitated sulphuret. According to Vogel, a reaction takes place between the calomel and sulphuret of antimony, resulting in the production of chloride of antimony and sulphuret of mercury. (*Annal. der Pharm.*, xxviii. 236.) The preparation was originally introduced to the notice of the profession by Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's pills.* The combination is well

* The following is the formula for the aloetic pills, usually called *dinner pills* or *Lady Webster's pills.* They are the *pilulæ stomachicæ* of the fifth edition of the Paris Codex, A.D. 1758. Take of the best aloes six drachms; mastic and red roses, each, two drachms; syrup of wormwood sufficient to form a mass, to be divided into pills of three grains each. Common syrup may be substituted for syrup of wormwood. One or two of these pills, taken shortly before a meal, will usually produce one free evacuation.

The Philadelphia College of Pharmacy has adopted the following formulas for the compound aloetic preparations commonly called *Hooper's* and *Anderson's pills.*

"*Hooper's female pills.* ℞. Aloës Barbadensis ℥viij, Ferri Sulphatis Exsiccati ℥ij, ʒiss, *vel* Ferri Sulphatis Crystal. ℥iv, Extracti Hellebori ℥ij, Myrrhæ ℥ij, Saponis ℥ij, Canellæ in pulv. tritæ ℥j, Zingiberis in pulv. trit. ℥j.—Beat them well together into a mass with water, and divide into pills, each containing two and a half grains." (*Journ. of the Phil. Col. of Pharm.*, v. 25.)

"*Anderson's Scots' pills.* ℞. Aloës Barbadensis ℥xxiv, Saponis ℥iv, Colocynthidis ℥j, Gambogiæ ℥j, Olei Anisi f℥ss. Let the aloes, colocynth, and gamboge be reduced to a very fine powder; then beat them and the soap with water into a mass, of a proper consistence to divide into pills, each containing three grains." (*Ibid.*)

adapted to the treatment of chronic rheumatism, and of scaly and other eruptive diseases of the skin, especially when accompanied with a syphilitic taint. Six grains of the U. S. preparation, and five of the British contain about one grain of calomel, and each U. S. pill about half a grain. One to two pills or more may be given morning and evening. W.

PILULÆ ASSAFŒTIDÆ. *U. S. Pills of Assafetida.*

"Take of Assafetida *a troyounce and a half;* Soap, in fine powder, *half a troyounce.* Beat them together with water so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

Each of these pills contains three grains of the gum-resin. They are a convenient form for administering assafetida, the unpleasant odour and taste of which render it very offensive in the liquid state. W.

PILULA CAMBOGIÆ COMPOSITA. *Br. Compound Pill of Gamboge.*

"Take of Gamboge, in powder, Barbadoes Aloes, in powder, Compound Powder of Cinnamon, of each, *one ounce;* Hard Soap, in powder, *two ounces;* Syrup *a sufficiency.* Mix the Powders together, add the Syrup, and beat the whole into a uniform mass." *Br.*

This is an active purgative pill, and may be given in the dose of from five to fifteen grains. The formula is that of Dr. George Fordyce simplified. W.

PILULÆ CATHARTICÆ COMPOSITÆ. *U. S. Compound Cathartic Pills.*

"Take of Compound Extract of Colocynth *half a troyounce;* Extract of Jalap, in fine powder, Mild Chloride of Mercury [calomel], each, *one hundred and eighty grains;* Gamboge, in fine powder, *forty grains.* Mix the powders together; then with water form a pilular mass, to be divided into one hundred and eighty pills." *U. S.*

This cathartic compound was first made officinal in the second edition of the U. S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action, and a peculiar tendency to the biliary organs. Such an officinal preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel; and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. Nor is it difficult, in this case, to reconcile the result of observation with physiological principles. Cathartic medicines act on different parts of the alimentary canal and organs secreting into it. In small doses, both the irritation which they occasion and their purgative effect are proportionably lessened. If several are administered at the same time, each in a diminished dose, it is obvious that the combined purgative effect of all will be experienced; while the irritation, being feeble in each part affected, and diffused over a large space, will be less sensible to the patient, and will more readily subside. In the compound cathartic pills, most of the active purgatives in common use are associated together in proportions corresponding with their respective doses, so that an excess of any one ingredient is guarded against, and violent irritation from this cause prevented. The name of the preparation may at first sight seem objectionable, as it might be applied to any compound pills possessing cathartic properties; but, when it is considered that the ingredients cannot all be expressed in the title, that no one is sufficiently prominent to give a designation to the whole, and that the preparation is intended as the representative of numerous cathartics, and calculated for a wide range of application, the name will not be considered an inexcusable deviation from ordinary medical nomenclature. It is

highly important, for the efficiency of these pills, that they be prepared in exact compliance with the directions, and that the *compound extract of colocynth* and the *extract of jalap* used be of good quality. When they fail, the result is generally ascribable to the substitution of jalap for the extract, or to the use of a compound extract of colocynth made with nearly inert scammony, inferior aloes, and insufficient colocynth, and altogether badly prepared.

Three of the pills, containing $10\frac{2}{3}$ grains of the mass, are a medium dose for an adult. In this quantity are four grains of compound extract of colocynth, three of extract of jalap, three of calomel, and two-thirds of a grain of gamboge. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required; but is particularly applicable to the early stages of bilious fevers, to hepatitis, jaundice, and all those derangements of the alimentary canal, or of the general health, which depend on congestion of the portal circle. W.

PILULA COLOCYNTHIDIS COMPOSITA. *Br. Compound Pill of Colocynth.*

"Take of Colocynth Pulp, in powder, *one ounce;* Barbadoes Aloes, in powder, Scammony, in powder, of each, *two ounces;* Sulphate of Potash, in powder, *a quarter of an ounce;* Oil of Cloves *two fluidrachms;* Distilled Water *a sufficiency.* Mix the Powders, add the Oil of Cloves, and beat into a mass with the aid of the Water." *Br.* The ounce employed is the avoirdupois ounce.

This is not, like the late London pills of the same name, merely another form of the compound extract of colocynth, though containing essentially the same materials; one great difference being that colocynth and aloes are used in substance in the pill, instead of in the state of extract. The present British preparation is that of the late Edinburgh Pharmacopœia slightly altered. Sulphate of potassa is used to promote the more complete division of the aloes and scammony. The preparation is actively cathartic in the dose of from five to twenty grains. W.

PILULA COLOCYNTHIDIS ET HYOSCYAMI. *Br. Pill of Colocynth and Hyoscyamus.*

"Take of Compound Pill of Colocynth *two ounces;* Extract of Hyoscyamus *one ounce.* Beat them into a uniform mass." *Br.*

This is an old officinal of the Edinburgh College. It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with extract of hyoscyamus, without losing any of their purgative power. The dose is from five to twenty grains. W.

PILULA CONII COMPOSITA. *Br. Compound Pill of Hemlock.*

"Take of Extract of Hemlock *two ounces and a half;* Ipecacuanha, in powder, *half an ounce;* Treacle *a sufficiency.* Mix the Extract of Hemlock and Ipecacuanha, and add sufficient Treacle to form a pill-mass." *Br.*

This is an old formula of the London College, discarded in the formation of the original British Pharmacopœia, but admitted into the present edition. The pill is an anodyne and expectorant combination, useful in chronic bronchial disease. The dose is from five to ten grains. W.

PILULÆ COPAIBÆ. *U. S. Pills of Copaiba.*

"Take of Copaiba *two troyounces;* Magnesia, recently prepared, *sixty grains.* Mix them together, and set the mixture aside until it concretes into a pilular mass, to be divided into two hundred pills." *U. S.*

When copaiba is mixed with pure magnesia, it gradually loses its fluidity, forming at first a soft tenacious mass, and ultimately becoming dry, hard, and brittle. The quantity of magnesia, and the length of time requisite for this change, vary with the condition of the copaiba; being greater in proportion to

the fluidity of this substance, or, in other words, to its amount of volatile oil. The quantity of magnesia directed by the Pharmacopœia, one-sixteenth of the weight of the copaiba, is sufficient to solidify the latter, as it is often found in the shops, in the course of six or eight hours; but, when the copaiba is fresh, or has been kept in closely stopped bottles, and retains, therefore, nearly the whole of its oil, it is necessary either to augment the proportion of magnesia, or to expose the mixture for a much longer time, or to diminish the volatile oil of the copaiba by evaporation. The magnesia combines chemically with the *copaivic acid* or hard resin, but, in relation to the volatile oil, acts merely as an absorbent; for, when the solidified mass is submitted to the action of boiling alcohol, a part is dissolved, abandoning the magnesia with which it was mixed, while the resin, combined with another portion of the earth remains undissolved. Varieties of copaiba, therefore, are solidifiable by magnesia, directly in proportion to the hard resin they contain, and inversely in proportion to the volatile oil; the soft resin being indifferent. According to Guibourt, copaiba, not solidifiable by magnesia, may be made so by adding one-sixth of Bordeaux or common European turpentine. In the preparation of the pills of copaiba, care should be taken to divide the mass before it has become too hard. The advantage of this preparation is, that the copaiba is brought to the state of pill with little increase of bulk. Each pill contains nearly five grains of copaiba, and from two to six may be taken for a dose twice or three times a day.

Hydrate of lime produces the same effect as magnesia, and, as stated by M. Thierry in a shorter time, if employed according to his formula. He takes 15 parts of copaiba and 1 part of slaked lime, mixes them in a marble mortar, transfers the mixture to an open vessel, places this upon a sand-bath, and sustains the heat for four hours, occasionally stirring. The hydrate of lime must have been freshly prepared from recently burnt lime. The mixture loses only a twenty-fourth of its weight, which is chiefly the water of the hydrate. (*Journ. de Pharm.*, 3e sér., i. 310.)

Notwithstanding the accuracy of the above statements, it sometimes happens that copaiba of undoubted genuineness, and with a due proportion of volatile oil, will not solidify with magnesia or with lime; and the cause of this uncertainty of action remained long undetermined. At length it has been ascertained by M. Z. Roussin, through a series of well-devised experiments, that the occasional want of solidifying power is owing to the absence of water, the presence of a certain quantity of which, whether in the copaiba or the earth employed, is essential to the combination of the magnesia or lime with the copaivic acid. In instances of deficiency in the solidifying property, M. Roussin recommends that the copaiba be shaken for some time with about one-twentieth of its weight of water, and then allowed to stand for some days in a warm place so as to allow all the water in excess to subside. The copaiba may now be decanted and preserved. Thus prepared it will solidify with one-sixteenth of calcined anhydrous magnesia, in the course of a few days, and often in twenty-four hours. (*Journ. de Pharm.*, 4e sér., i. 321–328.)

M. Rabot proposes a process by which the copaiba can in a few minutes be solidified to a consistence fit for preparing pills. He mixes pure copaiba with one-sixteenth of its weight of magnesia, previously slightly hydrated by sprinkling on it some drops of water, equal to about one-tenth of its weight, then introduces the capsule containing the mixture into boiling water, and keeps it thus by means of a water-bath for several minutes. The immediate consolidation is explained by the fact that the earth combines most readily with the resin of copaiba at a temperature of about 122° F., a heat which in no degree impairs the virtue of the medicine. (*Ibid.*, ii. 445.)

Pills may also be made by incorporating vegetable powders with copaiba so as to bring it to the proper consistence; but this method has the inconvenience of greatly increasing the bulk. Spermaceti and wax have been proposed as excipients; and the latter, which was originally suggested by J. F. Simon, is recommended by Mr. Maisch as retaining all the volatile oil, and, with some vegetable

powder, forming a mass that will retain its plasticity for years. One part, each, of wax, copaiba, and vegetable powder will answer the purpose, when the copaiba does not contain more than 50 per cent. of volatile oil; but if richer than this, it will require more of the excipient. To prepare the pills, melt the wax at the lowest possible heat, then gradually add the copaiba, and lastly incorporate some vegetable powder, as pulverized liquorice root, for example, with the other ingredients. (See *Am. Journ. of Pharm.*, Jan. 1863, p. 17.) W.

PILULÆ FERRI CARBONATIS. *U. S.*, *Br.* *Pills of Carbonate of Iron. Vallet's Ferruginous Pills.*

"Take of Sulphate of Iron *eight troyounces;* Carbonate of Soda *nine troyounces;* Clarified Honey *three troyounces;* Sugar, in coarse powder, *two troyounces;* Boiling Water *two pints;* Syrup *a sufficient quantity.* Dissolve the salts separately, each in a pint of the Water, a fluidounce of Syrup having been previously added to each pint. Mix the two solutions, when cold, in a bottle just large enough to hold them, close it accurately with a stopper, and set it by that the carbonate of iron may subside. Pour off the supernatant liquid, and, having mixed water, recently boiled, with Syrup in the proportion of a pint to the fluidounce, wash the precipitate with the mixture until the washings no longer have a saline taste. Place the precipitate on a flannel cloth to drain, and, having expressed as much of the water as possible, mix it immediately with the Clarified Honey and Sugar. Lastly, by means of a water-bath, evaporate the mixture, constantly stirring, until it is brought to the weight of eight troyounces." *U. S.*

"Take of the Saccharated Carbonate of Iron *one ounce;* Confection of Roses *a quarter of an ounce.* Beat them into a uniform mass." *Br.*

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharata* and *Syrupus Ferri Iodidi.* The U. S. pill of carbonate of iron is another example of a ferruginous preparation, in which the iron is protected from further oxidation by the same means. The salts employed are the same as those used for obtaining the officinal subcarbonate of iron; but, in forming that preparation, the carbonate which is at first precipitated absorbs oxygen, and loses nearly all its carbonic acid in the processes of washing and drying. When, however, as in the U. S. formula above given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with weak syrup also, the absorption of oxygen and loss of carbonic acid, during the separation of the precipitate, are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey and sugar, and evaporation by means of a water-bath. It is essential to the success of this process, that the sulphate of iron should be pure; otherwise some sesquioxide will be present in the product. The process is that of M. Vallet, of Paris, after whom the preparation is popularly called. The present U. S. process differs from that of 1850, in boiling the water for washing so as to expel the air, and in evaporating to a definite weight at the close, instead of to a proper consistence as before directed; both of which changes are improvements suggested by Dr. Squibb. (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 426.) The British pill of carbonate of iron is made from the saccharine carbonate, which is brought to the pilular consistence by being mixed with conserve of roses. This mode of making it is inferior to that of Vallet; for, in the first place, the saccharine carbonate is admitted to contain sesquioxide of iron, and secondly, conserve of roses, while it is a less efficient preservative of the pilular mass than honey and sugar, will, through its tannic acid, form an inky compound with the ferruginous sesquioxide. (See *Ferri Carbonas Saccharata*.)

Properties. The U. S. preparation is in the form of a soft pilular mass, of a dark greenish-gray colour, becoming black on exposure, and with a strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of carbonate of protoxide of iron. The cor-

responding pill, obtained from the saccharine carbonate, may be supposed to contain one-third of ferruginous matter.

Medical Properties. The U. S pill of carbonate of iron, or Vallet's ferruginous mass, is admirably adapted to cases in which chalybeate preparations are indicated. It is considered particularly useful in chlorosis, amenorrhœa, and other female complaints, and appears to act favourably by increasing the colouring matter of the blood, causing the capillary system to become more fully injected, and the lips to assume a redder colour. It may be given in divided doses to the extent of from ten to thirty grains in the course of the day, and continued for a month or six weeks, if improvement take place. As the mass is not divided in the U. S. formula, it is necessary in prescription to indicate the weight of each pill, which may vary from three to five grains, according to the views of the prescriber. There is little doubt that, when the alterative effects of iron are indicated, Vallet's preparation is one of the best that can be employed. Its chief merits are its unchangeableness and ready solubility in acids. For further information respecting it, see the favourable report made on Vallet's pills to the French Royal Academy of Medicine, in 1837, by M. Soubeiran, republished in the *Am. Journ. of Pharm.* (x. 244), and the paper on carbonate of iron by Professor Procter, in the same journal (x. 272).

Blaud's ferruginous pills, celebrated in France as a remedy in chlorosis, are prepared from equal weights of sulphate of iron and carbonate of potassa, made into a pilular mass with mucilage of tragacanth and powdered liquorice root. They contain, as the result of double decomposition, carbonate of protoxide of iron and sulphate of potassa. B.

PILULÆ FERRI COMPOSITÆ. *U. S. Compound Pills of Iron.*

"Take of Myrrh, in fine powder, *one hundred and twenty grains;* Carbonate of Soda, Sulphate of Iron, each, *sixty grains;* Syrup *a sufficient quantity.* Rub the Myrrh, first with the Carbonate of Soda, and afterwards with the Sulphate of Iron, until they are thoroughly mixed; then beat them with Syrup so as to form a pilular mass, to be divided into eighty pills." *U. S.*

This preparation is closely analogous to the Mistura Ferri Composita in properties and composition. It is a good emmenagogue and antihectic tonic. As its peculiar advantages depend upon the presence of carbonate of protoxide of iron, which speedily changes into the sesquioxide on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. It is said that the iron will be better preserved in the state of protoxide, if, instead of mixing the ingredients as directed in the Pharmacopœia, the operator should first dissolve the sulphate of iron, finely powdered, in the syrup, with a moderate heat, then add the carbonate of soda, stirring till they are thoroughly mixed, and lastly incorporate the myrrh. From two to six pills may be given at a dose three times a day. W.

PILULÆ FERRI IODIDI. *U.S.* Pilula Ferri Iodidi. *Br. Pills of Iodide of Iron.*

"Take of Iodine *half a troyounce;* Iron, in the form of wire and cut in pieces, *one hundred and twenty grains;* Sugar, in fine powder, *a troyounce;* Marshmallow, in fine powder, *half a troyounce;* Gum Arabic, in fine powder, Reduced Iron, each, *sixty grains;* Water *ten fluidrachms.* Mix the Iodine with a fluidounce of the Water in a thin glass bottle, add the Iron, and shake them together until a clear, green solution is obtained. Mix the Powders in a small porcelain capsule, and filter upon them, through a small filter, first the solution previously heated, and afterwards the remainder of the Water in order to wash the filter. Then, by means of a water-bath, with constant stirring, evaporate the whole to a pilular consistence, and divide the mass into three hundred pills.

"Dissolve sixty grains of Balsam of Tolu in a fluidrachm of Ether, shake the pills with the solution until they are uniformly coated, and put them on a plate to dry, occasionally stirring them until the drying is completed. Lastly, keep the pills in a well-stopped bottle.

"These pills are devoid of the smell of iodine; and distilled water, rubbed with them and filtered, does not colour solution of starch, or gives it only a slight blue tint." *U. S.*

"Take of Fine Iron Wire *forty grains;* Iodine *eighty grains;* Refined Sugar, in powder, *seventy grains;* Liquorice Root, in Powder, *one hundred and forty grains;* Distilled Water *fifty minims.* Agitate the Iron with the Iodine and Water in a strong stoppered ounce phial, until the froth becomes white. Pour the fluid upon the Sugar in a mortar, triturate briskly, and gradually add the Liquorice." *Br.*

The pills of iodide of iron were introduced, as a new officinal, into the U. S. Pharmacopœia at the revision of 1850. The U. S. pills are formed on the plan proposed by Prof. Procter, in imitation of *Blancard's pills* (*Am. Journ. of Pharm.*, May, 1860), and are much superior to those made by the U. S. process of 1850, or by that of the British Pharmacopœia. The iodine and iron unite directly to form the iodide of iron in solution, which is protected against the oxidizing influence of the air by the sugar and reduced iron into which the solution is dropped, while the marshmallow and gum serve to give due consistence and plasticity to the pilular mass. The pills are still further protected from the air by the impervious coating of balsam of Tolu, which readily yields to the softening and solvent properties of the gastric liquids. The great disadvantage of the pill of iodide of iron, as ordinarily prepared, is that it will not keep; crumbling by time and exposure, and evolving iodine in consequence of the oxidation of the iron. The preparation, made according to the U. S. formula, has stood the test of time; and we have seen pills which, four years after their preparation, exhibited no signs of change. Each pill contains about a grain of iodide of iron and one-fifth of a grain of reduced iron. The therapeutic uses of this preparation are the same as those of iodide of iron. (See *Ferri Iodidum.*) B.

PILULÆ GALBANI COMPOSITÆ. *U. S.* PILULA ASSAFŒTIDÆ COMPOSITA. *Br. Compound Pills of Galbanum. Compound Pill of Assafetida.*

"Take of Galbanum, Myrrh, each, *three hundred and sixty grains;* Assafetida *one hundred and twenty grains;* Syrup *a sufficient quantity.* Beat them together so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Assafetida, Galbanum, Myrrh, of each, *two ounces;* Treacle *an ounce.* Heat all together by means of a water-bath, and stir the mass until it assumes a uniform consistence." *Br.*

This compound is given as an antispasmodic and emmenagogue in chlorosis and hysteria. The dose is from five to twenty grains. W.

PILULÆ HYDRARGYRI. *U. S.* PILULA HYDRARGYRI. *Br. Pills of Mercury. Mercurial Pill. Blue Pill.*

"Take of Mercury *a troyounce;* Confection of Rose *a troyounce and a half;* Liquorice Root, in fine powder, *half a troyounce.* Rub the Mercury with the Confection until the globules cease to be visible; then add the Liquorice Root, and beat the whole into a pilular mass, to be divided into four hundred and eighty pills." *U. S.*

The *British* process is the same with the above, only that about double the quantity of materials are used, and no division of the mass into pills is directed.

This preparation is generally known by the name of *blue pill* or *blue mass.* The mercury constitutes one-third of the mass; and consequently the pill of our Pharmacopœia, weighing three grains, contains one grain of the metal.

The precise condition of the mercury in this preparation is somewhat uncertain. By far the greater proportion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into the protoxide, and that this is the ingredient upon which the activity of the pill depends. The supposed oxidation is attributed partly to the influence of the air

upon the surface of the metal, greatly extended by the separation of its particles, partly to the action of the substance used in the trituration. If the mercury be not oxidized during the trituration, there can be little doubt that it becomes so to a slight extent by subsequent exposure. The obvious changes which the mass undergoes by time can be explained in no other way; and protoxide of mercury is asserted to have been actually extracted from old mercurial pill. Nevertheless, it scarcely admits of dispute that the metal, quite independently of oxidation out of the body, is capable of producing the peculiar mercurial effects when introduced into the stomach, probably undergoing chemical changes there. According to M. Mialhe, mercury is slowly converted into corrosive sublimate in the stomach, under the combined agency of air and chloride of sodium. All agree that the efficacy of the preparation is proportionate to the extinction of the mercury, in other words, to the degree in which the metallic globules disappear. This extinction may be effected by trituration with various substances; and manna, syrup, honey, liquorice, mucilage, soap, guaiac, and extract of dandelion have been recommended, among others, for this purpose; but the confection of roses has been adopted in all the Pharmacopœias, as less liable to objection than any other. The mercury is known to be completely extinguished, when, upon rubbing a small portion of the mass with the end of the finger upon a piece of paper or glass, no globules appear. Powdered liquorice root is added in order to give due consistence to the mass. Some prefer for the purpose powdered marshmallow root. Mr. W. W. Stoddart has found that the extinguishment of the mercury, in the officinal process, is very much hastened by rubbing it first with the *powdered liquorice root*, moistened with a little distilled water or rose-water, and afterwards incorporating the confection. (*Am. Journ. of Pharm.*, xxviii. 162.) As the trituration requires to be long continued, and renders the process very laborious, it is customary to prepare the mass by machinery. At Apothecaries' Hall, in London, the trituration is effected by the agency of steam. The machine there employed consists of "a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axis." A machine for preparing blue mass, capable of being worked by the hand or by steam-power, has been invented by Mr. J. W. W. Gordon, of Baltimore, and, having been found to answer well, is in extensive use. It is described and figured in the *American Journal of Pharmacy* (xxi. 6). We have already referred, under *Hydrargyrum cum Cretâ*, to another ingenious apparatus invented by Dr. Squibb, by which the extinguishment of mercury is very satisfactorily effected.* Formerly much of the blue mass used in this country was imported; but at present the market is chiefly supplied by our own druggists. The preparation slowly changes colour upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury.†

* Mr. James Beatson, apothecary of the U. S. Naval Hospital at New York, found great advantage in the following mode of preparing the mercurial pill, which, while much easier than the officinal method, yields the same results. Instead of mixing the mercury with the confection, he first rubs it with the honey directed in the preparation of the confection, until the globules disappear, then adds the heated rose-water and sugar, and lastly the powdered red roses and liquorice root in succession, all in the officinal proportions. For the quantity of the material directed in the U. S. process for confection of roses, he employs 32 ounces of mercury. (*Am. Journ. of Pharm.*, xxiv. 204.)

† The mercurial pill is very apt to contain less than the due proportion of the metal. This was frequently the case with the mass as formerly imported. The fraud may be detected by the following plan of estimating the proportion of mercury, suggested by Prof. Reid, of New York, and modified by a committee of the Philadelphia College of Pharmacy. A certain weight of the mercurial pill, say fifty grains, is mixed with about one-fourth of its weight of iron filings, and introduced into a small green glass bulb, at the end of a somewhat curved tube, the open extremity of which is inserted, through a cork, into alcohol, contained in a broad-mouthed glass vial; another tube, open at both ends, passing through the cork in order to permit the escape of uncondensed gasses. Heat is then applied to the bulb by means of a spirit-lamp, is gradually increased until the glass becomes red hot, and continued for an hour. The alcohol in the vial dissolves the empyreumatic products, and, by being allowed to rise in the tube, and then expelled, serves

In consideration of the incomplete extinguishment of the mercury in many specimens of the blue pill, arising from the tedious process employed, Mr. F. B. Benger proposes to obtain the metal in a state of minute division. For this purpose he adds to a solution of an ounce of protochloride of tin, in a mixture of two drachms of hydrochloric acid and two ounces of cold water, a boiling-hot solution of 136 grains of corrosive sublimate in four ounces of distilled water, and stirs the mixture for a few seconds. The mercury of the corrosive chloride is thrown down in the form of a black powder, to which, after the liquid has been drawn off by means of a pipette, 30 grains of sugar, 100 grains of powdered liquorice, and about a drachm of glycerin are added. The mass being transferred to a porcelain slab, is allowed to become sufficiently dry, and then mixed with enough glycerin and liquorice to make it weigh 300 grains. (*Pharm. Journ. and Trans.*, 2d ser., ii. 165.) Theoretically, this appears to be a good process; but only a long experience of its practical advantages would justify its substitution for a plan which has been followed, for so many years, with results upon the whole so satisfactory. An obvious objection to the process is the possibility, with carelessness of manipulation, of having in the preparation a minute proportion of corrosive sublimate or bichloride of tin.

Medical Properties and Uses. These pills are among the mildest of the mercurials, being less liable than most others to act upon the bowels, and exercising the peculiar influence of the remedy upon the system with less irritation. They are much employed for producing the sialagogue and alterative action of mercury. For the former purpose, one pill may be given two or three times a day; and in urgent cases the dose may be increased. Even this preparation sometimes disturbs the bowels. It should then be given combined with a little opium, or in very minute doses, as half a grain or a grain of the mass, repeated every hour or two through the day, so as to allow of its absorption before a sufficient quantity has been administered to act as an irritant. With a view to the alterative effect upon the digestive organs, one pill may be given every night, or every other night, at bedtime, and followed in the morning, if the bowels should not be opened, by a small dose of laxative medicine. From five to fifteen grains of the mass are occasionally given as a cathartic, in cases requiring a peculiar impression upon the liver; but, when used for this purpose, it should always either be combined with or speedily followed by a more certain purgative. The *blue mass* may often be administered with advantage, suspended in water by the intervention of thick mucilage; and it forms an excellent addition to the chalk mixture in diarrhœa, particularly that of children, when the biliary secretion is deficient or otherwise deranged.* W.

PILULA IPECACUANHÆ CUM SCILLA. *Br. Pill of Ipecacuanha with Squill.*

"Take of Compound Powder of Ipecacuanha *three ounces;* Squill, in powder, Ammoniacum, in powder, of each, *one ounce;* Treacle *a sufficiency.* Mix the Powders and beat into a mass with the Treacle." *Br.*

This is a preparation of the late London Pharmacopœia, which, abandoned in the original preparation of the British Code, is recognised in the present. It

to wash out any mercury that may be condensed upon its sides. The alcohol is poured off from the condensed mercury, which is then washed with fresh alcohol, dried, and weighed. (See *Am. Journ. of Pharm.*, xvii. 151 and 309.)

* The blue pill is sometimes wanted in the state of powder; but, from its peculiar constitution, is not eligible for reduction to this form; as the mercury is disposed to aggregate during pulverization, and, from the honey it contains, it is apt, when pulverized, to attract moisture from the air. Mr. Ch. Bullock, therefore, recommends the following method of preparing a powder, which shall, as nearly as possible, represent the blue pill, in reference to its therapeutic effects. Take of finely powdered Elm-bark, finely powdered Sugar, and Mercury, equal parts, and of Alcohol a sufficiency. Rub the mercury with the powdered bark, adding from time to time enough alcohol to maintain a pasty consistence, till the mercury is completely extinguished; then spread the mass on paper to dry. When dry, powder it, add the sugar, and rub the mixture thoroughly until the powder will pass through a sieve of fine bolting cloth. (*Am. Journ. of Pharm.*, May, 1859, p. 271.)—*Note to the twelfth edition.*

is a good combination of expectorants, along with a little opium to allay irritation and restlessness, well adapted to chronic catarrh, with either deficient or greatly excessive expectoration, and to the advanced stages of the acute disease offering similar indications. The dose is from five to ten grains. W.

PILULÆ OPII. *U. S. Pills of Opium.*

"Take of Opium, in fine powder, *sixty grains;* Soap, in fine powder, *twelve grains.* Beat them together with water, so as to form a pilular mass, to be divided into sixty pills." *U. S.*

This process is designed merely to furnish a convenient formula for putting opium into the pilular form, preferable to the mode sometimes practised of making the pills directly from the unpowdered mass of opium as found in commerce. The soap answers no other purpose than to give a due consistence, and is therefore in small proportion. Each pill contains a grain of opium.

As hard old opium pills are sometimes preferred, in cases of irritable stomach, in consequence of their slow solution, it is proper for the apothecary to keep some in this state to meet the prescription of the physician.

Of the pills above directed, one is a medium dose in reference to the full effects of opium. W.

PILULA PLUMBI CUM OPIO. *Br. Pill of Lead and Opium.*

"Take of Acetate of Lead, in fine powder, *thirty-six grains;* Opium, in powder, *six grains;* Confection of Roses *six grains.* Beat them into a uniform mass." *Br.*

This pill would be better left to extemporaneous prescription; the requisite proportion of opium to the acetate varying in different cases. The tannic acid of the confection of roses decomposes a portion of the acetate; but the resulting tannate of lead is not inert. The mass contains six parts of the acetate of lead in eight, and may be given in the dose of two or three grains to begin with. W.

PILULÆ QUINIÆ SULPHATIS. *U. S.* PILULA QUINIÆ. *Br. Pills of Sulphate of Quinia. Pill of Quinia.*

"Take of Sulphate of Quinia *a troyounce;* Gum Arabic, in fine powder, *one hundred and twenty grains;* Clarified Honey *a sufficient quantity.* Mix the Sulphate of Quinia and Gum Arabic; then beat them with Clarified Honey so as to form a mass, to be divided into four hundred and eighty pills." *U. S.*

"Take of Sulphate of Quinia *sixty grains;* Confection of Hips *twenty grains.* Mix them to a uniform mass." *Br.*

As the pills made according to the U. S. directions are apt to become hard and of difficult solubility, when long kept, various other excipients have been recommended to obviate this disadvantage, such as honey alone, and confection of roses, as in the Br. formula. Glycerin also has been proposed; and a little of it added to the other ingredients of the U. S. pills would probably improve their consistence. Mr. Edward Parrish has long been in the habit of preparing pills of sulphate of quinia, by taking 20 grains of the salt, adding 15 drops of aromatic sulphuric acid, and triturating until the mixture assumes a pilular consistence. Though at first liquid, the mixture soon thickens, and finally becomes quite solid. The officinal sulphate is thus rendered more soluble by combining with an additional eq. of sulphuric acid. The advantages of this process are the solubility of the resulting pill, and the smallness of its bulk. A five-grain pill thus made is not inconveniently large. (*Am. Journ. of Pharm.*, xxv. 292.)

Each of the U. S. pills contains a grain of the sulphate of quinia, and twelve are equivalent to an ounce of good Peruvian Bark. The dose of the Br. pill is only one-fourth less than that of the sulphate of quinia itself. W.

PILULÆ RHEI. *U. S. Pills of Rhubarb.*

"Take of Rhubarb, in fine powder, *three hundred and sixty grains;* Soap, in fine powder, *one hundred and twenty grains.* Beat them together with water so as to form a pilular mass, to be divided into one hundred and twenty pills." *U. S.*

Rhubarb is so often given in the pilular form, that it is convenient both for the physician and apothecary to have an officinal formula, indicating the mode of preparing the pills, as well as the quantity of rhubarb to be contained in each. Soap, as directed by the U. S. Pharmacopœia, has stood the test of long experience as a good excipient for rhubarb. We have found rhubarb pills, made with compound tincture of cardamom, without other ingredient, to answer an excellent purpose. Each officinal pill contains three grains of rhubarb. W.

PILULÆ RHEI COMPOSITÆ. *U. S.* PILULA RHEI COMPOSITA. *Br. Compound Pills of Rhubarb. Compound Rhubarb Pill.*

"Take of Rhubarb, in fine powder, *a troyounce;* Socotrine Aloes, in fine powder, *three hundred and sixty grains;* Myrrh, in fine powder, *half a troyounce;* Oil of Peppermint *half a fluidrachm.* Beat them together with water so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Rhubarb Root, in powder, *three ounces;* Socotrine Aloes, in powder, *two ounces and a quarter;* Myrrh, in powder, Hard Soap, in powder, of each, *one ounce and a half;* Oil of Peppermint *one fluidrachm and a half;* Treacle, by weight, *four ounces.* Mix the Powders with the Oil, then add the Treacle, and beat the whole into a uniform mass." *Br.*

This is a warm tonic laxative, useful in costiveness with debility of stomach. From two to four pills, or from ten to twenty grains of the mass, may be taken twice a day. W.

PILULÆ SAPONIS COMPOSITÆ. *U. S.* PILULA SAPONIS COMPOSITA. *Br.* PILULA OPII. *Br.* 1864. *Compound Pills of Soap. Compound Pill of Soap.*

"Take of Opium, in fine powder, *sixty grains;* Soap, in fine powder, *half a troyounce.* Beat them together with water so as to form a pilular mass." *U. S.*

"Take of Opium, in powder, *half an ounce;* Hard Soap, in powder, *two ounces;* Distilled Water *a sufficiency.* Mix the Opium and Soap, and beat into a mass with the Water." *Br.*

This preparation is useful by affording the opportunity of conveniently administering opium, in a pilular and readily soluble form, in small fractions of a grain. The name now used in both Pharmacopœias was probably intended to conceal the nature of the preparation from the patient. One grain of opium is contained in five of the mass. W.

PILULÆ SCILLÆ COMPOSITÆ. *U. S.* PILULA SCILLÆ COMPOSITA. *Br. Compound Pills of Squill. Compound Squill Pill.*

"Take of Squill, in fine powder, *sixty grains;* Ginger, in fine powder, Ammoniac, in fine powder, each, *one hundred and twenty grains;* Soap, in fine powder, *one hundred and eighty grains;* Syrup *a sufficient quantity.* Mix the powders together; then beat them with Syrup so as to form a pilular mass, to be divided into one hundred and twenty pills." *U. S.*

"Take of Squill, in powder, *one ounce and a quarter;* Ginger, in powder, Ammoniacum, in powder, Hard Soap, in powder, of each, *one ounce;* Treacle, by weight, *two ounces*, or *a sufficiency.* Mix the Powders, add the Treacle, and beat into a uniform mass." *Br.*

This is a stimulating expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of chronic affections of the bronchial mucous membrane. From five to ten grains may be given three or four times a day. The preparation should be made when wanted for immediate use, as the squill which it contains is liable to be injured by keeping. W.

PLUMBUM.

Preparations of Lead.

Of the Preparations formerly considered under this head, *Solution of Subacetate of Lead* and *Diluted Solution of Subacetate of Lead* have been trans-

ferred to the LIQUORES or *Solutions;* and *Iodide of Lead* is the only one remaining.

PLUMBI IODIDUM. *U.S., Br. Iodide of Lead.*

"Take of Nitrate of Lead, Iodide of Potassium, each, *four troyounces;* Distilled Water *a sufficient quantity.* With the aid of heat, dissolve the Nitrate of Lead in a pint and a half, and the Iodide of Potassium in half a pint of Distilled Water, and mix the solutions. Allow the precipitate formed to subside, and, having poured off the supernatant liquid, wash it with Distilled Water, and dry it with a gentle heat." *U. S.*

The process of the British Pharmacopœia is the same as the above, and almost in the identical words.

In this process the nitrate of lead gives up its metal to the iodine, from which it receives the potassium; the operation taking place between single equivalents of the several ingredients. The nitrate of potassa thus formed remains in solution, while the iodide of lead is precipitated. The saturating proportions of nitrate of lead and iodide of potassium are 165·6 of the former and 165·5 of the latter, or almost precisely equal quantities. The proportions should be as nearly as possible those of exact saturation. An excess of the iodide of potassium, independently of the waste, has the disadvantage of holding a portion of the iodide of lead in solution; while, according to Christison, an excess of lead over the iodine disposes to the formation of the lemon-yellow insoluble oxyiodide of lead. By the use of equal quantities of the two salts, these disadvantages are avoided. As iodide of lead is slightly soluble in cold water, it is desirable to use as little of the menstruum as will answer; and hence the comparatively small proportion of water employed.

Iodide of lead, though all the three Colleges gave processes for it, was omitted in the first British Pharmacopœia. It has, however, been admitted into the present edition. In the London process acetate of lead was employed instead of the nitrate; but M. Depaire, of Brussels, ascertained that, in this process, a considerable amount of iodine remains in solution after the precipitation of the iodide of lead; and M. F. Boudet states that the quantity of the iodide resulting from the process is 10 per cent. less than theory would indicate. By the addition of nitric acid to the solution, after precipitation, an additional quantity of iodide of lead is obtained. M. Boudet ascribes this result to the formation of a portion of soluble iodide of potassium and lead, whenever iodide of lead and acetate of potassa are in contact. By substituting nitrate for acetate of lead, he found that a quantity of iodide of lead was obtained, as near that required by theory as the solubility of the iodide of lead permits. (*Journ. de Pharm.*, 3e sér., xi. 274.)

From the above remarks it would appear that the present officinal process is on the whole to be preferred to that in which the acetate of lead is used, and especially as the nitrate is more easily obtained pure. Some interesting experiments have been made by M. T. Huraut, of Paris, on the different methods of preparing iodide of lead. It may be obtained by the reaction between any of the soluble iodides and the soluble salts of lead. It resulted from his observations that of the two salts of lead employed, the nitrate was to be preferred, and of the various iodides, though iodide of potassium yielded a very handsome product, yet iodide of calcium afforded one not inferior in quality, and somewhat greater in quantity. Upon a small scale, as the process is performed by the apothecary, the difference would be of little or no consequence; but it might be important to the manufacturer. (See *Am. Journ. of Pharm.*, xxi. 228.)

As obtained by the above process, iodide of lead is in the form of a bright yellow, heavy, tasteless, inodorous powder. It is soluble in 1235 parts of cold water (Soubeiran, *Trait. de Pharm.*), and 194 of boiling water, which, on cooling, deposits it in minute, shining, golden-yellow, crystalline scales. It melts by heat, and is dissipated in vapours, which are at first yellow, and ultimately violet in consequence of the disengagement of the iodine. It consists of one equivalent of iodine 126·3, and one of lead 103·6 = 229·9. As a test of its purity, the Edinburgh College stated that five grains are entirely dissolved, with the aid

of heat, by a fluidrachm of pyroligneous acid, diluted with a fluidounce and a half of distilled water; and golden crystals are copiously deposited when the solution cools. According to the late London Pharmacopœia, 100 grains of it, dissolved at a boiling heat in nitric acid diluted with two parts of water, will, after the expulsion of the iodine, yield with sulphate of soda, a precipitate of sulphate of lead weighing 66 grains. It should be kept excluded from the light. It is stated by Engelhardt that iodine is separated from iodide of lead by the perchlorides of iron and copper; while the other metallic chlorides, whether bichlorides, sesquichlorides, or protochlorides, have no such effect, producing compounds of iodides of the metal employed with chlorides of lead. (*Chem. Gaz.*, Jan. 15, 1856, p. 24.)

Medical Properties and Uses. This compound is supposed to have the resolvent properties of iodine, combined with those which are peculiar to lead, and was at one time recommended in tuberculous diseases, in which, however, it has proved wholly inefficient. It is said to have been usefully employed in the discussion of scrofulous tumours and other indolent swellings, and in the cure of obstinate ulcers; and for these purposes has been used both internally, and locally in the form of an ointment. According to Dr. Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. (*Christison's Dispensatory.*) The dose is from half a grain to three or four grains. Dr. O'Shaughnessy states that ten grains are borne without inconvenience.

W.

POTASSA.

Preparations of Potassa.

Of the preparations formerly embraced in this category, the *Solution of Potassa*, the *Solution of Citrate of Potassa*, and the *Compound Solution of Iodide of Potassium*, Lond., Dub., under the altered name of *Liquor Iodi*, Br., have been transferred to the Liquores or *Solutions; Pure Nitrate of Potassa*, Dub, has been treated of in *Part* I. of this work; and the following preparations, at one time officinal, have been omitted in the existing Pharmacopœias; namely, *Solution of Carbonate of Potassa*, U. S., Lond., Dub., *Sulphate of Potassa with Sulphur*, Ed., and *Bisulphate of Potassa*, Ed., Dub.

POTASSA. *U. S.* Potassa Caustica. *Br.* Kali Purum. *Potassa. Caustic Potassa. Hydrate of Potassa.*

"Take of Solution of Potassa *eight pints*. Evaporate it rapidly in an iron vessel, over the fire, until ebullition ceases, and the Potassa melts. Pour this into suitable moulds, and keep it, when cold, in a well-stopped bottle." *U. S.*

"Take of Solution of Potash *two pints* [Imperial measure]. Boil down the Solution of Potash rapidly in a silver or clean iron vessel, until there remains a fluid of oily consistence, a drop of which when removed on a warm glass rod solidifies on cooling. Pour this into proper moulds, and when it has solidified, and while it is still warm, put it into stoppered bottles." *Br.*

The concrete alkali, obtained from these processes, is the hydrate of potassa, sufficiently pure for medicinal purposes. The solution of the alkali freed from carbonic acid having been obtained by another formula (see *Liquor Potassæ*), the formation of the present preparation requires merely the evaporation of this solution until the whole of its uncombined water is driven off. The evaporation must be performed in metallic vessels, as those of glass or earthenware are acted on by the alkali; and it should be completed as quickly as possible, in order to abridge the period during which the solution would be liable to absorb carbonic acid from the atmosphere. When poured out on a metallic plate or dish, the cake, just as it concretes, may be marked with a knife in the directions in which it is to be divided, and when cold it readily breaks in those directions. A better plan, however, is to run the fused alkali into suitable moulds, as directed in the U. S. and British formulas. These should be made of iron and have a

cylindrical shape, which is the most convenient form of the alkali for surgical use. Green glass bottles with ground stoppers are best adapted for preserving this preparation, as white flint glass is slightly acted on.

Properties, &c. In its officinal form, potassa is in sticks having a fibrous fracture, and, when properly prepared from pure materials, white and somewhat translucent; but, as often found in the shops, they have a dingy gray or greenish colour, with occasionally a bluish tint, and the peculiar odour of slaking lime. It is extremely caustic and very deliquescent, and dissolves in less than its weight of water, leaving but a slight residue. Its aqueous solution agrees in properties with Liquor Potassæ. It is also readily soluble in alcohol. When exposed to a low red heat it melts, and at bright redness is volatilized. On account of its deliquescent property, and its strong attraction for carbonic acid, it requires to be kept in very accurately stopped bottles. In the state here described, the alkali is united with water, forming hydrate of potassa. As formerly obtained by the U. S., London, and Edinburgh formulas, from solution of potassa derived from an impure carbonate, it contained various impurities, which, however, did not interfere with its medicinal value; such as chloride and teroxide of potassium, sesquioxide of iron, lime, silica, alumina, sulphate of potassa, and a portion of the alkali still in a carbonated state. As our officinal solution of potassa, from which the alkali is now prepared, is made from the bicarbonate, the resulting potassa is purer than as formerly obtained. According to the U. S. Pharmacopœia, it is dissolved by water and alcohol, with the exception of a slight residue, which probably consists chiefly of undecomposed carbonate, as this is insoluble in alcohol. Officinal potassa may be rendered nearly pure by digestion in alcohol, which takes up only the hydrated alkali, evaporating the solution to dryness, and fusing the dry mass obtained. *Hydrate of Potassa*, when thus procured, is called *alcoholic potassa*. It is generally in flat white pieces, which are dry, hard, brittle, and extremely caustic. Its other properties are similar to those of the impure hydrate above described. According to Mr. H. Wurtz, of New York, alcoholic potassa usually contains a trace of silicate of potassa, which appears to be taken up by the alcohol. The source of this is the carbonate of potassa employed, which may be freed from this impurity by evaporating its aqueous solution, in a sheet-iron dish, to dryness, and adding, from time to time, lumps of carbonate of ammonia. The silicate is thus converted into the carbonate; and, on dissolving the residue, the silica appears in flakes, which may be separated by filtration. (*N. Y. Journ. of Pharm.*, Feb. 1852.) Potassa may be discriminated from the other fixed alkalies (soda and lithia) by affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric acid, and a yellow one with bichloride of platinum. Potassa imparts to the flame of burning alcohol in which it is dissolved a reddish tint; soda colours it yellow even in the presence of potassa; and thus a method is afforded of detecting an admixture of the latter with the former alkali. According to Bunsen, when the flame is regarded through a glass of a cobalt blue colour, only the colour imparted by potassa is seen, that peculiar to soda not being able to penetrate through blue glass. (*Journ. de Pharm.*, Oct. 1860, p. 319.) The officinal potassa, apart from impurities, consists of one eq. of dry potassa 47·2, and one of water 9 = 56·2. Dry potassa is composed of one eq. of potassium 39·2, and one of oxygen 8 = 47·2. B.

Medical Properties and Uses. This is the old *causticum commune acerrimum* or *strongest common caustic*. It is a powerful escharotic, quickly destroying the life of the part with which it comes in contact, and extending its action to a considerable depth beneath the surface. In this latter respect, it differs from nitrate of silver or lunar caustic, to which it is, therefore, preferred in forming issues and opening abscesses. It has been used for removing stricture of the urethra; but in consequence of its tendency to spread, it may, unless carefully applied, produce such a destruction of the lining membrane, as to open a passage for the urine into the cellular tissue. The most convenient mode of employing the caustic for the formation of an issue, is to apply to the skin a piece of linen spread with adhesive plaster, having a circular opening in its centre cor-

responding with the intended size of the issue, and then to rub upon the skin, within the opening, a piece of the caustic previously moistened at one end. The application is to be continued till the life of the part is destroyed, when the caustic should be carefully washed off with a wet sponge or wet tow, or neutralized by vinegar. The preparation is also employed for forming solutions of potassa of definite strength, whether for medicinal or pharmaceutic use. A solution of one drachm and a half of caustic potassa in two fluidounces of distilled water was highly recommended by the late Dr. Hartshorne, of Philadelphia, as an application to the spine in tetanus. It may be applied by means of a sponge attached to the end of a stick, which should be drawn quickly along the back from the nape of the neck to the sacrum. It produces a powerful rubefacient effect.*

Pharm. Uses. In the preparation of Ether, *U. S.*

POTASSA CUM CALCE. *U. S. Potassa with Lime.*

"Take of Potassa, Lime, each, *a troyounce.* Rub them together so as to form a powder, and keep it in a well-stopped bottle." *U. S.*

This preparation is a grayish-white powder, sometimes called *Vienna caustic.* It should not effervesce on the addition of an acid. It is prepared for use by being made up into a paste with a little alcohol. The paste is applied to the part to be cauterized for ten or fifteen minutes, and is conveniently limited in its operation by a piece of adhesive plaster, in the manner explained under potassa. The former Edinburgh preparation, made by evaporating the solution of potassa to one-third, and adding lime enough to bring it to the state of a firm paste, was often called *causticum commune mitius* or *milder common caustic.* Potassa with lime is a more manageable caustic than the officinal potassa, on account of the presence of the lime, which renders it milder, slower in its operation, and less deliquescent, and causes it to spread less beyond the part intended to be affected. Dr. Filhos has improved this caustic by forming it in sticks. To prepare it thus, the potassa is perfectly fused in an iron spoon, and one-third of its weight of quicklime is added in divided portions; the whole being stirred with an iron rod. The fused mass is then run into lead tubes, closed at one end, about three inches long, and from a quarter to half an inch in diameter in the clear. The sticks are kept, still enclosed in the lead tubes with the open end downwards, in thick glass tubes, containing some powdered quicklime, and closed with a cork, between which and the stick some cotton is put to steady the caustic. When employed, as much of the caustic is uncovered at the end, by scraping off the lead, as it is proposed to use. This form of caustic is particularly recommended for cauterizing the neck of the uterus. M. E. Robiquet has modified the caustic, by fusing the potassa and lime at a higher heat, running the fused mass into iron moulds, and quickly coating the sticks, when cold, with melted gutta-percha. The higher heat employed renders the caustic harder and more homogeneous.† B.

* At the suggestion of Dr. Maunoury, of Chartres, M. E. Robiquet has prepared a paste consisting of gutta-percha and caustic potassa, which offers many advantages of manipulation, in the application of the latter substance. It is prepared by simply melting together equal weights of the two substances. The resulting paste can be moulded into any form that may be thought desirable, either of cylinders, plates, or lozenges, and retains its form indefinitely, even when introduced into cavities. All that is necessary, before applying it, is to dip it into alcohol for a few seconds. The resulting eschars are very precise in their form. (*Journ. de Pharm.*, xxx. 275.)—*Note to the eleventh edition.*

† M Piedagnel has found that by mixing the Vienna powder with muriate of morphia, in the proportion of three parts of the former to one of the latter, a caustic is obtained which will produce an eschar without causing pain. He first mixes them intimately in the dry state, and then with alcohol, chloroform, or water, makes a paste, which may be applied by means of adhesive plaster. (*Journ. de Pharm.*, 3e sér., xxxiii 469.)– *Note to the twelfth edition.*

POTASSÆ ACETAS. *U. S., Br. Acetate of Potassa.*

"Take of Acetic Acid *a pint;* Bicarbonate of Potassa *a sufficient quantity.* Add the Bicarbonate gradually to the Acid until this is saturated; then filter the solution, and evaporate cautiously, by means of a sand-bath, until a dry salt remains. Lastly, keep this in a well-stopped bottle." *U. S.*

"Take of Carbonate of Potash *twenty ounces* [avoirdupois]; Acetic Acid [sp. gr. 1·044] *two pints* [Imperial measure], or *a sufficiency.* To the Acetic Acid, placed in a thin porcelain basin, add gradually the Carbonate of Potash, filter, acidulate, if necessary, with a few additional drops of the Acid, and, having evaporated to dryness, raise the heat cautiously so as to liquefy the product. Allow the basin to cool, and, when the salt has solidified, and while it is still warm, break it in fragments, and put it into stoppered bottles." *Br.*

The process for forming this acetate is a case of single elective affinity. The substitution in the present Pharmacopœia, of the bicarbonate of potassa for the carbonate used in the formula of 1850, is an improvement, as it ensures a purer product. The form of acid for generating the salt directed in both Pharmacopœias is officinal acetic acid. Distilled vinegar should never be employed, on account of organic impurity, which gives the solution, when concentrated, a reddish or brownish colour. When acetic acid is used, a colourless solution is obtained. This is evaporated to dryness, according to the U. S. and British Pharmacopœias; but the latter, following the late Dublin Pharmacopœia, directs the dry salt to be melted, so that it may be obtained as a solid mass on cooling. When fusion is resorted to, great care must be taken not to use too high a heat; as otherwise part of the acetic acid will be decomposed, and the resulting salt will be discoloured. For drying the acetate of potassa, Dr. Christison considers the heat of a vapour-bath too low, and that of a sand-bath apt to become too high. He, therefore, recommends the use of a bath of chloride of calcium when operating on a small scale. In conducting the evaporation, it is best to have the solution always slightly acid; for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration.

Acetate of potassa may also be obtained by double decomposition between acetate of lead and sulphate of potassa. When thus procured it is very white and pure, but liable to the objection, for medical use, that it may possibly contain a little lead. Another method by double decomposition is between acetate of lime and sulphate of potassa.

Properties, &c. Acetate of potassa when pure is a white salt, perfectly neutral to test paper, unctuous to the touch, and of a warm, pungent, saline taste. When unskilfully prepared it is apt to be more or less coloured. Its state of aggregation differs with the manner in which it is prepared. As obtained by evaporating the solution to dryness, agreeably to the directions of the U. S. Pharmacopœia, it is in the form of soft fibrous masses. As usually prepared and found in the shops, it has a foliated texture, which is given to it by fusion and cooling. On account of this appearance it was formerly called *foliated earth of tartar.* This salt is extremely deliquescent, and, if exposed to the air, becomes converted into a liquid of an oleaginous appearance. It is on account of this property that it must always be preserved in well-stopped bottles. It dissolves in about half its weight of water, and twice its weight of alcohol. Anything remaining undissolved by these menstrua is impurity. Heated above its point of fusion, it is decomposed into acetone and carbonate of potassa; the acetic acid being resolved into that volatile liquid and carbonic acid. When treated with sulphuric acid, acetous vapours are copiously evolved, and sulphate of potassa is formed; and a blood-red colour is produced by a solution of sesquichloride of iron. One hundred grains of the salt, decomposed by sulphuric acid, furnish a salt (sulphate of potassa), which, after exposure to a strong heat, weighs 88·8 grains. (*Lond. Pharm.*) The most usual impurities contained in it are sulphate and tartrate of potassa, chloride of potassium, and the salts of lead and copper. A soluble sulphate may be detected by chloride of barium; and chloride of potassium, or other soluble chloride, by nitrate of silver added to a *dilute* solution. If the ni-

trate be added to a concentrated solution, crystals of acetate of silver will be precipitated, soluble in water or dilute nitric acid. With bichloride of platinum it yields a yellow, and with tartaric acid a crystalline precipitate, showing it to be a salt of potassa. If tartrate of potassa be present, it will remain undissolved when the salt is acted on by alcohol. Lead and copper may be detected by sulphuretted hydrogen and ferrocyanide of potassium; the former test producing with the lead a blackish, and the latter with the copper a brown precipitate. Since the introduction of the cheap method of obtaining pure acetic acid from wood, this salt has scarcely been subjected to adulteration. Acetate of potassa is incompatible with the mineral acids, which expel the acetic acid; with the sulphates of soda and magnesia; with corrosive sublimate and nitrate of silver; and with several other earthy and metallic salts. This salt exists in the juices of many plants, and especially in the sap of trees, and is the principal source of the carbonate of potassa existing in the ashes of wood. It consists of one eq of acetic acid 51, one of potassa 47·2, and two of water 18 = 116·2.

Medical Properties and Uses. Acetate of potassa acts as a diuretic in doses of from a scruple to a drachm, and as a mild cathartic when given to the extent of two or three drachms. It is employed in dropsies, and often with good effect. The late Dr. Duncan, of Edinburgh, considered it to be a medicine of great efficacy, and one of our best saline deobstruents. Dr. J. A. Easton, of Glasgow, has found it useful in several skin diseases, such as psoriasis, eczema, and lepra. Cases which had resisted the ordinary remedies were cured, after a treatment occupying from three weeks to two months. The dose given by Dr. Easton was half a drachm, three times a day, dissolved in water. The remedy seemed to act through the kidneys, the urine being remarkably increased, both in its aqueous and solid contents. The late Dr. Golding Bird treated a large number of cases of acute rheumatism with remarkable success with this salt. The pain of the disease declined as soon as the urine became alkaline and rose in specific gravity. The quantity given, in twenty-four hours, was half an ounce in divided doses, largely diluted with water. (*Braithwaite's Retrospect*, Am. ed., July, 1854, p. 43.) It has been highly recommended by Ambrosoli, in large doses, as a remedy in acute and subacute urethritis with mucous or puruloid discharge, and in similar affections of the vagina and uterus. (*Ann. de Thérap.*, 1863, p. 115.) Acetate of potassa may be made extemporaneously in the liquid form by saturating distilled vinegar with carbonate of potassa. Two drachms of the carbonate, saturated with vinegar, will sometimes produce in hydropic cases ten or twelve stools, and a copious discharge of urine. (*Duncan.*) Acetate of potassa, like the other alkaline salts containing a vegetable acid, may be given in the uric acid diathesis, to render the urine alkaline; for the experiments of Wöhler have shown that the acid of these salts undergoes decomposition in the digestive and assimilating processes, while the alkali enters the current of the circulation. From the decided property which this salt possesses of increasing the secretion of the kidneys, it was formerly called *sal diureticus* or *diuretic salt.*

Off. Prep. Tinctura Ferri Acetatis, *Br.* B.

POTASSÆ CARBONAS. *U. S.*, *Br.* *Carbonate of Potassa. Carbonate of Potassa from Pearlash.*

"Take of Impure Carbonate of Potassa [pearlash] *thirty-six troyounces;* Water *two pints and a half.* Dissolve the Impure Carbonate in the Water, and filter the solution; then pour it into an iron vessel, and evaporate over a gentle fire until it thickens. Lastly, remove it from the fire, and stir constantly with an iron spatula until it forms a granular salt." *U. S.*

The British Pharmacopœia defines this salt as "KO,CO_2, with about 16 per cent. of water of crystallisation;" and states that it is "obtained from common commercial pearl-ash, by treating it with its own weight of distilled water, and evaporating the solution to dryness, while kept briskly agitated."

The object of the above process is to purify the impure carbonate of potassa, or pearlash. This generally contains certain insoluble impurities, as well as small

portions of sulphate and silicate of potassa, and chloride of potassium, as explained under another head. (See *Potassæ Carbonas Impurus.*) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are got rid of, as well as the greater part of the foreign salts, which, being much less soluble than the carbonate of potassa, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of *cold water*, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor obtained by decantation or filtration is then evaporated to dryness. The officinal process is conducted very much in this way; cold water being employed, and about equal weights of alkali and water being used. The prolonged contact of the water with the salt, and the occasional stirring of the mixture, formerly ordered by the Dublin College, were useful directions. In no case should the undissolved residue be washed with a fresh portion of water; as, by such a proceeding, the foreign salts, which it is the object of the process to separate, would be dissolved. Iron vessels are directed, because this metal is not acted on by the alkali, while glass is attacked by it. In granulating the salt by stirring, it is better, when the solution is brought nearly to dryness, to keep it on the fire at a reduced heat until the process is finished, than to remove it the moment it thickens.

According to Berzelius, a more productive process for purifying pearlash, though the resulting salt is not so pure as when obtained in the way just described, is to dissolve the pearlash in more than its weight of water, to evaporate the solution till it has the sp. gr. 1·52, and then to put it in a cool place, that the foreign salts, principally sulphate of potassa and chloride of potassium, may crystallize. The solution is then decanted, and evaporated to dryness.

To get rid of the silica, Rieckher proposes to evaporate the solution, exempt from sulphate, to dryness, to moisten the residue with solution of carbonate of ammonia, and again evaporate. The silica separates, and passes into the insoluble state at the temperature necessary for evaporation. By again dissolving and evaporating, the carbonate is obtained free from this impurity. (*Chem. Central Blatt*, 1863, p. 158.)

Properties, &c. Carbonate of potassa, as found in the shops, is in the form of a coarse, granular, white powder, having a nauseous, alkaline taste, and acting as an alkali on vegetable colours. It is very soluble in water, dissolving in its weight of that liquid, but is insoluble in alcohol. It is extremely deliquescent; and hence a portion of it, exposed to the air for some time, attracts so much water as completely to dissolve into an oily liquid, called by the older chemists, *oleum tartari per deliquium*. On account of this property, carbonate of potassa should be kept in bottles with accurately ground stoppers. If exposed in its usual state to a red heat, it retains its carbonic acid, but loses 16 per cent. of water; and when decomposed by dilute sulphuric acid, evolves 26·3 per cent. of carbonic acid. (*Lond. Pharm.*) It should be completely soluble in water; but, generally, a small insoluble portion is left of earthy matter. The usual impurities are earthy matters, sulphate of potassa, chloride of potassium, and silica in the state of silicate of potassa. When dissolved in water and treated with nitric acid in excess, it affords a faint cloudiness with chloride of barium, and a slight precipitate with nitrate of silver; effects showing the presence of minute portions of a sulphate and of a chloride. The nitric solution is also precipitated by carbonate of soda, if earthy matter be present. If the indications of these tests are decided, the salt is below the officinal standard of purity. Its aqueous solution, saturated by an acid, slowly deposits a slight flocculent precipitate of hydrated silica. It is incompatible with acids and acidulous salts, muriate and acetate of ammonia, lime-water, chloride of calcium, sulphate of magnesia, alum, tartar emetic, nitrate of silver, ammoniated copper and ammoniated iron, sulphate of iron, tincture of chloride of iron, calomel and corrosive sublimate, acetate and subacetate of lead, and sulphate of zinc. It is not decomposed by tartrate of iron and potassa. According to the Br. Pharmacopœia, "83 grains

require for neutralisation at least 980 grain-measures of the *volumetric solution of oxalic acid;*" and "20 grains neutralise 17 grains of citric acid, or 18 grains of tartaric acid."

Composition. Carbonate of potassa, after exposure to a red heat, is anhydrous, consisting of one eq. of carbonic acid 22, and one of potassa $47{\cdot}2 = 69{\cdot}2$. Obtained by the officinal formulas, it is, according to Mr. Phillips, a sesquihydrate, containing two eqs. of carbonate and three of water. When exposed to the air, carbonate of potassa absorbs sufficient water, before losing its solid form, to give it three equivalents; with more it begins to deliquesce. (Dr. Pohl. See *Am. Journ. of Pharm.*, Nov. 1861, p. 532.) B.

Medical Properties and Uses. Purified pearlash is the form of carbonate of potassa usually employed in this country, where it is frequently, though incorrectly, called *salt of tartar;* the latter name being strictly applicable to the purer carbonate obtained by decomposing cream of tartar. It is occasionally used as an antacid in dyspepsia, a diuretic in dropsy, and antilithic in gravel attended with red deposits in the urine; but the purpose to which it is most commonly applied is the formation of the *neutral mixture* and *effervescing draught.* (See *Liquor Potassæ Citratis.*) It is also used with advantage in some cases of jaundice, in which it probably operates by entering the circulation, and directly exciting the hepatic function. It has enjoyed considerable popular reputation mixed with cochineal in hooping-cough, and is supposed by some, in common with other alkaline remedies, to operate favourably in pseudomembranous inflammations of the mucous tissues. It is considered among the most effectual remedies in obstinate cutaneous eruptions, in which it is employed both internally and externally. The dose is from ten to thirty grains, given in some aromatic water sweetened with sugar. In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours. A case is recorded in which an adult female swallowed about three ounces in very concentrated solution, with the most alarming effects, though the patient ultimately recovered, with a long and very painful convalescence. (Dr. Espagne, *Arch. Gén.*, Fév. 1867, p. 233.) The antidotes are the fixed oils and vegetable acids.

As a local remedy in cutaneous affections, carbonate of potassa is used in the form of bath, of lotion, and of ointment. From eight to sixteen ounces may be used for a single bath, the quantity being gradually increased. Lotions may be made by dissolving two or three drachms in a pint of water; and ointments, by rubbing from ten grains to a drachm with an ounce of lard.

A solution of the salt, on exposure to the air, or on the addition of an acid, deposits flocculi consisting of hydrate of silica, resulting from the decomposition of silicated potassa, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbonic acid.

POTASSÆ CARBONAS PURA. *U. S. Pure Carbonate of Potassa. Salt of Tartar.*

"Take of Bicarbonate of Potassa, in coarse powder, *twelve troyounces.* Put it into a capacious iron crucible, heat gradually until the water of crystallization is driven off; then raise the heat to redness, and maintain that temperature for half an hour. Having taken the crucible from the fire, and allowed it to cool, dissolve its contents in Distilled Water, and filter the solution. Then pour it into an iron vessel, and evaporate over a gentle fire until it thickens. Lastly, move it from the fire, and stir constantly with an iron spatula, until it forms a granular salt." *U. S.*

In this process the bicarbonate of potassa is ignited, whereby it loses its water of crystallization and second equivalent of carbonic acid, and is reduced to the state of carbonate. As the bicarbonate is a very pure salt, so the carbonate obtained from it is also very pure.

The pure carbonate was formerly obtained from bitartrate of potassa, by first purifying it by solution and crystallization, and then incinerating it; and this was one of the processes of the late Edinburgh Pharmacopœia. The tartaric acid, which consists of carbon, hydrogen, and oxygen, is decomposed, and gives rise, among other products, to carbonic acid, which combines with the potassa. The matter, after ignition, contains, besides carbonate of potassa, certain impurities derived from the bitartrate. These are carbonate of lime arising from the decomposition of tartrate of lime, alumina, and minute portions of the oxides of iron and manganese; but, being all insoluble in water, they are left behind when the mass is acted on by that liquid, the alkaline carbonate being taken up. Some silicate of potassa is sometimes dissolved, derived from silica, either originally in the bitartrate, or derived from the earthenware or porcelain crucible in which the ignition is performed.

Pure carbonate of potassa may also be obtained by deflagrating a mixture of two parts of bitartrate of potassa, and one of nitrate of potassa. This process has been objected to on the ground that it gives a carbonate, apt to contain a little of the poisonous cyanide of potassium. But this objection is unfounded. It is true, as Engelhardt and Wicke have proved, that the deflagrated mass contains cyanate of potassa; but this is entirely decomposed into ammonia and carbonate of potassa by the subsequent operations of solution and evaporation to dryness, to which the mass is subjected.

It was this origin from bitartrate of potassa, called in its impure state *tartar*, that gave rise to the name of *salt of tartar*, still frequently applied to the purer forms of the carbonate. It may, indeed, be very much doubted whether the real salt of tartar is often kept in our shops; the ordinary carbonate, as purified from pearlash, being generally substituted for it, and answering, in most cases, every medicinal purpose that could be expected from the use of the purer salt.

M. Lunge prepares what he considers the pure carbonate by carrying still further the officinal process for carbonate of potassa described in the preceding article. After procuring the carbonate as there directed, he dissolves it again in water, and, having permitted the solution to stand, decants and evaporates to dryness on a furnace. Dissolving the product anew, he evaporates the solution until, upon cooling, it deposits all the sulphate of potassa in crystals. He then separates the mother-water, and again evaporates until, on cooling, the liquid sets in a solid mass, which is the pure carbonate. (*Journ. de Pharm. et de Chim.*, Avril, 1868, p. 275.)

Properties, &c. Pure carbonate of potassa, obtained from the bicarbonate or cream of tartar, differs from the same salt procured from pearlash, in containing no impurities. With the tests mentioned under the carbonate it gives negative indications, showing the entire absence of foreign substances. The U. S. Pharmacopœia gives the following characters of the salt. It is white, deliquescent, and wholly soluble in water; effervesces with acids, and has an alkaline reaction; yields, in solution, a yellow precipitate with bichloride of platinum, and a white one effervescing with acids, with sulphate of magnesia; when saturated with an acid deposits nothing upon standing, and, when treated with pure nitric acid in excess, is not precipitated by carbonate of soda, chloride of barium, or nitrate of silver. It loses 16 per cent. of its weight at a red heat.

Medical Properties and Uses. These are the same with those of the carbonate of potassa described in the preceding article. The pure carbonate, on account of its freedom from silica, furnishes the best material for forming the solution of citrate of potassa, or neutral mixture.

POTASSÆ BICARBONAS. *U. S., Br. Bicarbonate of Potassa.*

"Take of Carbonate of Potassa *forty-eight troyounces;* Distilled Water

ten pints. Dissolve the Carbonate in the Distilled Water, and pass carbonic acid through the solution till it is fully saturated. Then filter the liquid, and evaporate that crystals may form, taking care that the heat does not exceed 160°. Lastly, pour off the supernatant liquid, and dry the crystals upon bibulous paper. Carbonic acid may be obtained from marble by the addition of dilute sulphuric acid." *U. S.*

"Take of Carbonate of Potash *one pound* [avoirdupois]; Distilled Water *two pints* [Imperial measure]; Hydrochloric Acid *one pint and a half* [Imp. meas.]; Water *three pints* [Imp. meas.]; White Marble, in fragments, *one pound* [avoird.], or *a sufficiency.* Dissolve the Carbonate of Potash in the Distilled Water, and filter the solution into a three-pint bottle, capable of being tightly closed by a cork traversed by a glass tube sufficiently long to pass to the bottom of the fluid. Introduce the Marble into another bottle, in the bottom of which a few small holes have been drilled, and the mouth of which is closed by a cork, also traversed by a glass tube, and place the bottle in a jar, of the same height as itself, but of rather larger diameter. Connect the two glass tubes, air-tight, by a caoutchouc tube. The cork of the bottle containing the Carbonate of Potash having been placed loosely, and that of the bottle containing the Marble tightly, in its mouth, pour into the jar surrounding the latter bottle the Hydrochloric Acid, previously diluted with the Water. When carbonic acid gas has passed through the potash solution for two minutes so as to expel the whole of the air of the apparatus, fix the cork tightly in the neck of the bottle, and let the process go on for a week. At the end of this time numerous crystals of Bicarbonate of Potash will have formed, which are to be removed, shaken with twice their bulk of cold Distilled Water, and, after decantation of the water, drained, and dried on filtering paper by exposure to the air. The mother-liquor, filtered, if necessary, and concentrated to one-half, at a temperature not exceeding 110°, will yield more crystals. The tube immersed in the solution of Carbonate of Potash, which should have as large a diameter as possible, may require the occasional removal of the crystals formed within it, in order that the process may not be interrupted." *Br.*

In these processes, the carbonate of potassa, consisting of one eq. of acid and one of base, is combined with an additional equivalent of carbonic acid. The combination is effected by passing a stream of this acid through a solution of the carbonate, so long as it is absorbed. In the U. S. formula the distilled water taken is about three times the weight of the carbonate. As the bicarbonate of potassa requires four times its weight of water to dissolve it, the quantity of water ordered in the U. S. formula would seem not to be sufficient to dissolve the new salt; unless it be assumed that the solution becomes heated in consequence of the reaction. The solution of the whole of the new salt is not intended in the British process, which proceeds on the plan of forming crystals of bicarbonate at once in the original solution, without concentration by heat. The filtration directed in the U. S. formula is ordered on the presumption that the whole of the bicarbonate formed is dissolved; and is intended to separate silica, which is always deposited during the progress of the saturation, when carbonate of potassa from pearlash is employed. On a small scale the saturation of the carbonate is best conducted in a Wolfe's apparatus of three bottles; the first containing water to wash the carbonic acid gas, the two others, solutions of the carbonate. The bottles should be connected by means of wide tubes, to prevent their being obstructed by the crystals formed. On a large scale the saturation is performed in strong vessels, into which the carbonic acid is driven under pressure. Sulphuric acid is always used by the manufacturing chemist for generating the carbonic acid; but in small operations, muriatic acid, diluted with twice its bulk of water, is more convenient; inasmuch as it generates with the marble or chalk a soluble salt (chloride of calcium), which does not interfere with the extrication of the carbonic acid, as the insoluble sulphate of lime does. In the British process dilute muriatic acid is used for the extrication of the carbonic acid, which is effected in a self-regulating generator of that gas.

In the process of the late Ed. Pharmacopœia, carbonate of ammonia was incorporated with carbonate of potassa, by the assistance of a little water, so as to form a uniform pulp, which was dried by a gentle heat. By the combined influence of the volatility of the ammonia, and the affinity of the carbonate of potassa for carbonic acid, the carbonate of ammonia was totally decomposed; its carbonic acid generating the bicarbonate by uniting with the carbonate, and its ammonia being evolved during the drying of the pulp, which was then reduced to a fine powder. This process is alleged by Dr. Christison to be superior to the other "in point of economy, dispatch, and certainty in small operations."

Mr. Brande gives the following proportions for the preparation of bicarbonate of potassa on the large scale: "100 lbs. of purified carbonate of potassa are dissolved in 17 gallons of water, which, when saturated with carbonic acid, yield from 35 to 40 lbs. of crystallised bicarbonate; 50 pounds of carbonate of potassa are then added to the mother-liquor, with a sufficient quantity of water to make up 17 gallons, and the operation repeated."

Wöhler states that charcoal, when mixed with the carbonate, facilitates by its porosity, in a remarkable degree, the formation of the bicarbonate. Thus he found that, when crude tartar was charred in a covered crucible, and the carbonaceous mass, after having been slightly moistened with water, was subjected to a stream of carbonic acid, the gas was absorbed with great rapidity, and heated the mass so considerably, as to render it necessary to surround the vessel with cold water, to prevent the decomposition of the bicarbonate formed. When the temperature diminished, the saturation was known to be completed. The mass was lixiviated in the smallest quantity of water at the temperature of from 85° to 100°, and the solution, after filtration and cooling, deposited the greater part of the bicarbonate in fine crystals. (See *Am. Journ. of Pharm.*, x. 82.)

M. Behrens has proposed to obtain bicarbonate of potassa by partially saturating the carbonate, dissolved in an equal weight of water, with acetic acid gradually added. Up to a certain point, no carbonic acid is extricated, and a precipitate takes place of pure bicarbonate of potassa, equal to half the weight of the carbonate employed. After the bicarbonate is separated, the saturation may be completed, and acetate of potassa obtained. (*Journ. de Pharm.*, 3e sér., iv. 464.) The bisalt is also produced when the carbonate is treated with weak lemon-juice in forming the citrate. (See *page* 1269.)

According to Berzelius, the cheapest method of obtaining the bicarbonate of potassa is to suspend a concentrated solution of the purified carbonate, contained in a stoneware dish, within a cask, over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbonic acid, and, by absorbing it, crystallizes into bicarbonate in the course of five or six weeks. Distillers and brewers may prepare this salt with great facility by suspending the alkaline solution in the fermenting tun. The salt in powder called *sal aëratus*, made principally in New England, is, we believe, prepared in this way. In composition it is between a carbonate and bicarbonate.

Properties, &c. Bicarbonate of potassa is in transparent, colourless crystals, slightly alkaline to the taste and to test paper, permanent in the air, and having the shape of irregular eight-sided prisms with two-sided summits. It dissolves in four times its weight of cold water, and in five-sixths of its weight of boiling water, by which it is partially decomposed, and converted into *sesquicarbonate*. It is insoluble in alcohol. Exposed to a red heat, it loses 30·7 per cent., comprising half its carbonic acid and the whole of its water of crystallization, and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method is now adopted in the U.S. Pharmacopœia for obtaining the pure carbonate. Treated with nitric acid in excess, it should give a clear solution, the transparency of which is not disturbed by chloride of barium, and but slightly by nitrate of silver. When a perfect bicarbonate, its solution, unless heated, does not precipitate a solution of sulphate of magnesia. This negative indication, however, cannot be depended upon as showing the absence of carbonate; for, according to Dr. Christison, no precipitate will be occasioned

even when 50 per cent. of this impurity is present. Bicarbonate of potassa does not decompose calomel. When dissolved in 40 parts of water, it produces a white haze merely with a solution of corrosive sublimate; but if it contain so much as a hundredth part of carbonate, a brick-red precipitate is immediately produced. (*Christison.*) Another way of detecting the presence of carbonate is to add starch sugar to a heated solution of the suspected bicarbonate. If any carbonate be present, the mixture turns yellow or brown. (*Chevallier.*) Bicarbonate of potassa consists of two eqs. of carbonic acid 44, one of potassa 47·2, and one of water 9 = 100·2. "Fifty grains exposed to a low red heat, leave 34·5 grains of a white residue, which requires for exact saturation 500 grain-measures of the *volumetric solution of oxalic acid;*" and "20 grains neutralise 14 grains of citric acid, or 15 grains of tartaric acid." *Br.*

Medical Properties. The medical properties of this salt are similar to those of the carbonate, to which it is preferable from its milder taste, and greater acceptability to the stomach. The dose is from twenty grains to a drachm. Dr Garrod, of London, has had great success in the treatment of acute rheumatism by the use of two-scruple doses of this salt, given in weak solution, every two hours, day and night, and continued for a few days after the articular affection and febrile disturbance have subsided. The salt probably acts by rendering the secretions alkaline, and by increasing the alkalinity of the blood. For this purpose it is much better than the carbonate, which is not well borne by the stomach when continued for any length of time.

POTASSÆ CITRAS. *U. S., Br. Citrate of Potassa.*

"Take of Citric Acid *ten troyounces;* Bicarbonate of Potassa *fourteen troyounces;* Water *a sufficient quantity.* Dissolve the Citric Acid in two pints of Water, add the Bicarbonate gradually, and, when effervescence has ceased, strain the solution and evaporate to dryness, stirring constantly, after a pellicle has begun to form, until the salt granulates. Then rub it in a mortar, pass it through a coarse sieve, and keep it in a well-stopped bottle." *U. S.*

"Take of Carbonate of Potash *eight ounces* [avoirdupois], or *a sufficiency;* Citric Acid, in crystals, *six ounces* [avoird.], or *a sufficiency;* Distilled Water *two pints* [Imperial measure]. Dissolve the Citric Acid in the Water, add the Carbonate of Potash gradually, and, if the solution be not neutral, make it so by the cautious addition of the Acid or the Carbonate of Potash. Then filter, and evaporate to dryness, stirring constantly, after a pellicle has begun to form, till the salt granulates. Triturate in a dry, warm mortar, and preserve the powder in stoppered bottles." *Br.*

Citrate of potassa was first recognised as officinal in the U. S. Pharmacopœia of 1850. It was known formerly by the name of *salt of Riverius.* In the above U. S. formula, mutually saturating proportions of the acid and bicarbonate were intended to be employed; the latter ingredient being preferred to the carbonate on account of its greater purity. The potassa of the bicarbonate unites with the citric acid, to form the citrate of potassa, and the carbonic acid escapes, producing effervescence. The resulting solution is directed to be evaporated to dryness, as affording the most convenient form for use. The granulation ordered has a tendency to retard the deliquescence of the citrate. The British process differs only in the use of the carbonate instead of bicarbonate, and by providing more carefully for an exact neutralization.

Citrate of potassa is crystallizable, but, as procured by the above process, is in the form of a white granular powder. It is inodorous, of a saline, slightly bitterish, not unpleasant taste, deliquescent, very soluble in water without residue, and insoluble in alcohol. It is stated in the U. S. Pharmacopœia that its solution does not change the colour of litmus; but we have found a carefully prepared specimen slightly to redden the paper; and the acid used in the process is theo-

retically in slight excess. By a red heat, with exposure to the air, the salt is decomposed, leaving a residue of pure carbonate of potassa. The presence of tartaric acid would be indicated by a precipitate of bitartrate of potassa on the addition of muriatic acid.

The British Pharmacopœia gives the following tests of its character. Heated with sulphuric acid it forms a brown fluid, and gives off inflammable vapours with the odour of acetic acid. Its solution, mixed with a solution of chloride of calcium, remains clear till it is boiled, when a white precipitate is formed readily soluble in acetic acid. This is a character of citric acid, which, in saline combination, unites with lime to form the insoluble citrate only when heated. Acidulated with hydrochloric acid, the solution gives a yellow precipitate with perchloride of platinum; showing that the base of the salt is potassa. "One hundred and two grains, heated to redness till gases cease to be evolved, leave an alkaline residue [carbonate of potassa], which requires for exact neutralisation 1000 grain-measures of the *volumetric solution of oxalic acid.*" *Br.*

As citric acid is tribasic, this salt consists of three eqs. of potassa and one of acid; its formula being $3KO,C_{12}H_5O_{11}$.

Medical Properties. Citrate of potassa is a grateful refrigerant diaphoretic, and has long been used in the fevers of this country, in the extemporaneous forms of neutral mixture and effervescing draught. As these require time and a somewhat careful manipulation in their preparation, it has been found more convenient to keep the citrate of potassa ready made, and dissolve it in water when wanted for use. This solution will no doubt produce the essential diaphoretic and refrigerant effects of the neutral mixture or effervescing draught; but is less agreeable to the stomach and palate, because destitute of the carbonic acid contained in these preparations. The dose of the citrate is from twenty to twenty-five grains. (See *Liquor Potassæ Citratis*, p. 1268.) W.

POTASSÆ ET SODÆ TARTRAS. *U. S.* Soda Tartarata. *Br.* Sodæ et Potassæ Tartras. *Br.* 1864, *U. S.* 1850. Sodæ Potassio-tartras. *Lond.* *Tartrate of Potassa and Soda. Tartrate of Soda and Potassa. Tartarated Soda. Rochelle Salt.*

"Take of Carbonate of Soda *twelve troyounces;* Bitartrate of Potassa, in fine powder, *sixteen troyounces;* Boiling Water *five pints.* Dissolve the Carbonate of Soda in the Water, and gradually add the Bitartrate of Potassa. Filter the solution, and evaporate until a pellicle begins to form; then set it aside to crystallize. Pour off the mother-water, and dry the crystals on bibulous paper. Lastly, evaporate the mother-water, that it may furnish more crystals." *U. S.*

"Take of Acid Tartrate of Potash, in powder, *sixteen ounces* [avoirdupois], or *a sufficiency;* Carbonate of Soda *twelve ounces* [avoird.], or *a sufficiency;* Boiling Distilled Water *four pints* [Imperial measure]. Dissolve the Carbonate of Soda in the Water, add gradually the Acid Tartrate of Potash, and, if after being boiled for a few minutes the liquid has an acid or alkaline reaction, add a little Carbonate of Soda or Acid Tartrate of Potash till a neutral solution is obtained. Boil and filter; concentrate the liquor till a pellicle forms on the surface, and set it aside to crystallise. More crystals may be obtained by again evaporating as before." *Br.*

This is a double salt, consisting of tartrate of potassa combined with tartrate of soda; or if the bibasic view of tartaric acid is accepted, a tartrate of potassa and soda, as its name imports, consisting of one eq. of tartaric acid with one of each of the alkalies. The theory of its formation is very simple, being merely the saturation of the excess of acid in the bitartrate of potassa by the soda of the carbonate of soda, the carbonic acid of which escapes with effervescence. The quantities of the materials for mutual saturation are 143·3 parts of carbonate and 188·2 of bitartrate, or one eq. of each. This gives the ratio of 3 to 3·95. The proportion adopted in the U. S. and Br. Pharmacopœias is as 3 to 4, which is very near the theoretical quantities. As the salts employed are apt to vary in composition and purity, the carbonate from the presence of more or less water

of crystallization, and the bitartrate from containing tartrate of lime, it is, perhaps, best in all cases, after indicating the nearest average proportion as a general guide, to present to the operator the alternative of using the cream of tartar to the point of exact saturation.

Properties. Tartrate of potassa and soda is in the form of colourless, transparent, slightly efflorescent crystals, often very large, and having the shape, when carefully prepared, of right prisms, with ten or twelve unequal sides. As ordinarily crystallized, they are generally in half prisms, as if split in the direction of their axis. The salt has a saline and slightly bitter taste. It dissolves in 2·5 parts of cold water, and in much less boiling water. Any undissolved residue is impurity, probably tartrate of lime or bitartrate of potassa, or both. Its solution is neutral to test paper, and yields no precipitate with chloride of barium, or a dilute solution of nitrate of silver. The non-action of these tests shows the absence of sulphates and chlorides. As it is sometimes largely adulterated with sulphate of soda (F. Mahla, *Am. Journ. of Pharm.*, Nov. 1868, p. 548), the former test may be important. When the salt is exposed to a strong heat, it blackens, and gives out inflammable gases with the odour of burnt sugar; the tartaric acid being destroyed, and a mixture of the carbonates of potassa and soda left. It sometimes contains tartrate of lime, which may be removed by solution and crystallization; but when the crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with all acidulous salts except bitartrate of potassa. It is also decomposed by the acetate and subacetate of lead, by the soluble salts of lime, and by those of baryta, unless the solution of the tartrate be considerably diluted. The way in which acids act in decomposing it, is by combining with the soda, and throwing down bitartrate of potassa as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle, and hence is frequently called *Seignette's salt*, or *Rochelle salt.*

Composition. Tartrate of potassa and soda consists of two eqs. of tartaric acid 132, one of potassa 47·2, one of soda 31·3, and eight of water 72 = 282·5; or, considered as a double salt, of one eq. of tartrate of potassa 113·2, and one of tartrate of soda 97·3, with the same quantity of water. If tartaric acid is bibasic, it must be considered as consisting, the eight eqs. of water being left out of the question, of one eq. of each of its other three constituents, the equivalent of the acid being doubled. "One hundred and forty-one grains of it, heated to redness till gases cease to be evolved, leave an alkaline residue which requires for neutralisation 1000 grain-measures of the *volumetric solution of oxalic acid.*" *Br.*

Medical Properties and Uses. This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescing aperient called Seidlitz powders. (See *Pulveres Effervescentes Aperientes.*) The dose as a purge is from half an ounce to an ounce. Given in small and repeated doses it does not purge, but is absorbed, and renders the urine alkaline. (Millon and Laveran, *Journ. de Pharm.*, 3e sér., vi. 222.)

Tartrate of potassa and magnesia, formed by saturating cream of tartar with carbonate of magnesia, has been proposed by M. Maillier as a safe and pleasant purgative. (*Journ. de Pharm.*, xiii. 252.)

Off. Prep. Pulveres Effervescentes Aperientes, *U. S.* B.

POTASSÆ TARTRAS. *U. S., Br. Tartrate of Potassa. Soluble Tartar.*

"Take of Carbonate of Potassa *sixteen troyounces;* Bitartrate of Potassa [cream of tartar], in fine powder, *thirty-six troyounces*, or *a sufficient quantity;* Boiling Water *eight pints.* Dissolve the Carbonate of Potassa in the Water; then gradually add Bitartrate of Potassa to the solution until it is completely saturated, and boil. Filter the liquid, evaporate it until a pellicle forms, and

set it aside to crystallize. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stopped bottle." *U. S*

"Take of Acid Tartrate of Potash *twenty ounces* [avoirdupois], or *a sufficiency;* Carbonate of Potash *nine ounces* [avoird], or *a sufficiency;* Boiling Distilled Water *two pints and a half* [Imperial measure]. Dissolve the Carbonate of Potash in the Water; add by degrees the Acid Tartrate of Potash, and if, after a few minutes' boiling, the liquid is not neutral to test paper, make it so by the careful addition of more of the Carbonate or of the Acid Tartrate. Then filter, concentrate till a pellicle forms on the surface, and set it aside to cool and crystallise. More crystals may be obtained by evaporating and cooling the mother-liquor. Drain the crystals, dry them by exposure to the air in a warm place, and preserve them in a stoppered bottle." *Br.*

In these processes, the excess of acid in the bitartrate is saturated by the potassa of the carbonate, the carbonic acid is extricated with effervescence, and the neutral tartrate of potassa is formed. On account of the greater solubility of the carbonate than of the bitartrate, the former is first dissolved, and the latter added to the solution to full saturation. As the bitartrate is gradually added, the mutual action of the salts should be promoted by constant stirring, and the addition continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified quantity of the bisalt; since, from its variable quality, it is impossible to adjust precisely the proportions applicable to all cases. It is necessary that the solution should be exactly neutral, or a little alkaline; and hence, if inadvertently too much bitartrate has been used, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered in order to separate tartrate of lime, which appears in white flocks, and which is always present in cream of tartar as an impurity. The evaporated liquor should then be placed in *warm* earthenware vessels, to ensure a slow refrigeration; and, after remaining at rest for several days, the crystals begin to form. In order that the crystallization should proceed favourably, it is necessary, according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in any part of the process; as this metal is apt to discolour the salt.

Tartrate of potassa is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid of the bitartrate is neutralized by means of carbonate of lime. This generates an insoluble tartrate of lime, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum.*)

Properties, &c. Tartrate of potassa, prepared according to the officinal processes, is in white crystals, which are neutral to test paper, slightly deliquescent, and usually in the form of irregular six-sided prisms with dihedral summits. Its taste is saline and bitter. It dissolves in its own weight of cold, and in half its weight of boiling water (*Wittstein*), and is nearly insoluble in alcohol. Exposed to heat it undergoes fusion, swells up, blackens, and is decomposed; being converted into carbonate of potassa. For medical use it should be crystallized; but, as it ordinarily occurs in the shops, it is a white granular powder, obtained by evaporating the solution to dryness, while it is constantly stirred. In this state it is said to require four times its weight of water for solution. It is not known to be purposely adulterated; but, if obtained by evaporation to dryness, it is liable to contain an excess of carbonate or bitartrate of potassa, when it will have either an alkaline or acid reaction. It is decomposed by all the strong acids, and by many acidulous salts, which cause the precipitation of minute crystals of bitartrate of potassa, by abstracting one eq. of alkali from two of the salt. Chloride of barium or acetate of lead occasions a white precipitate of tartrate of baryta or lead, distinguishable from the sulphate of those bases by being wholly soluble in dilute nitric acid. Tartrate of potassa is composed of one eq of potassa 47·2, and one of tartaric acid 66 = 113·2, or, if tartaric acid be considered as bibasic, of two eqs. of base 94·4 and one of acid 132 = 226·4.

According to Berzelius, the crystals contain no water of crystallization. "One hundred and thirteen grains, heated to redness till gases cease to be evolved, leave an alkaline residue, which requires for exact neutralisation 1000 grain-measures of the *volumetric solution of oxalic acid.*" *Br.*

Medical Properties. Tartrate of potassa is a mild, cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to febrile diseases, and is occasionally combined with senna, the griping effects of which it has a tendency to obviate. The dose is from a drachm to an ounce, according to the degree of effect desired. B.

POTASSII BROMIDUM. *U. S., Br. Bromide of Potassium.*

"Take of Bromine *two troyounces;* Iron, in the form of Filings, *a troyounce;* Pure Carbonate of Potassa *two troyounces and sixty grains;* Distilled Water *four pints.* Add the Iron, and afterwards the Bromine, to a pint and a half of the Distilled Water, stirring the mixture frequently with a glass rod for half an hour. Apply a gentle heat, and, when the liquid assumes a greenish colour, add gradually the Pure Carbonate of Potassa, previously dissolved in a pint and a half of the Distilled Water, until it ceases to produce a precipitate. Continue the heat for half an hour, and then filter. Wash the precipitate with the remainder of the Distilled Water, boiling hot, and again filter. Mix the filtered liquids, and evaporate that crystals may form. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stopped bottle." *U. S.*

"Take of Solution of Potash *two pints* [Imperial measure]; Bromine *four fluidounces* [Imp. meas.], or *a sufficiency;* Wood Charcoal, in fine powder, *two ounces* [avoirdupois]; Boiling Distilled Water *one pint and a half* [Imp. meas.]. Put the Solution of Potash into a glass or porcelain vessel, and add the Bromine in successive portions, with constant agitation, until the mixture has acquired a permanent brown tint. Evaporate to dryness; reduce the residue to a fine powder, and mix this intimately with the Charcoal. Throw the mixture in small quantities at a time into a red-hot iron crucible, and, when the whole has been brought to a state of fusion, remove the crucible from the fire and pour out its contents. When the fused mass has cooled dissolve it in the Water, filter the solution through paper, and set it aside to crystallise. Drain the crystals, and dry them with a gentle heat. More crystals may be obtained by evaporating the mother-liquor and cooling. The salt should be kept in a stoppered bottle." *Br.*

In the first step of the U. S. process, a solution of bromide of iron is formed; and this, by the addition of the solution of carbonate of potassa, is decomposed so as to generate carbonate of the protoxide of iron which precipitates, and bromide of potassium in solution. By straining, the precipitated carbonate is separated, and from the strained liquor crystals of bromide of potassium are obtained by due evaporation. In the Br. process, by reaction between potassa and bromine, the bromide of potassium and bromate of potassa are produced in solution, and, having been obtained dry by evaporation, are exposed with the powder of charcoal to a red heat, whereby the bromate of potassa is converted into bromide of potassium by the separation of its oxygen. The remainder of the process consists in obtaining the bromide in crystals by solution in boiling water, which deposits it on cooling.

Properties, &c. Bromide of potassium is a permanent, colourless, anhydrous salt, crystallizing in cubes or quadrangular prisms, and having a pungent, saline taste, similar to that of common salt, but more acrid. It is very soluble in cold water, more so in hot, and but slightly soluble in alcohol. When heated it decrepitates, and, at a red heat, fuses without decomposition. If its aqueous solution be mixed with a little chlorine water, and then shaken with ether, the bromine, separated by the chlorine, will be dissolved by the ether, which will rise to the surface of a red colour. The salt may thus be known to be a bromide. That the base is potassium may be known by the white crystalline precipitate produced by tartaric acid added to its solution. The following characters are given of the salt in the U. S. Pharmacopœia. "Its aqueous solution does not

affect the colour of litmus or turmeric, and is not precipitated by chloride of barium. When mixed with starch and treated with sulphuric acid, it becomes yellow. The salt, when subjected to heat, does not lose weight. Ten grains of it require, for complete precipitation, 14·30 grains of nitrate of silver [840 grain-measures of the *volumetric solution of nitrate of silver, Br.*]; and the precipitate formed has a yellowish colour." The object of adding sulphuric acid with the starch, is to set the bromine free. If iodine be set free at the same time, the starch will assume a violet or feeble blue colour. To test for iodine in this salt, Lassaigne recommends to add to its solution a few drops of chlorine water, and then to introduce a piece of starched white paper. If iodine be present, the starch will become violet, or faintly blue; and iodide of potassium, which is not an unfrequent impurity, may thus be detected. The absence of iodine is to be inferred from the non-production of a blue colour, upon the addition of a drop of an aqueous solution of bromine or chlorine to a solution of the salt mixed with mucilage of starch. *Br.* If the salt decomposes more nitrate of silver than is above stated, its saturating power is greater than it should be, and the presence of a chloride, probably of potassium or sodium, may be suspected. Chlorides may be more certainly detected by precipitating the salt with nitrate of silver, and treating the precipitate with a slight excess of ammonia. If there be a chloride, the chloride of silver will be thrown down, to be dissolved by the ammonia; and the solution thus obtained, if treated with nitric acid in excess, will throw down a white precipitate of chloride of silver. (*Journ. de Pharm.*, Dec. 1863, p. 514.) An iodide of an alkaline metal will be detected by adding to the solution of the bromide the chloride of palladium, which will precipitate all the iodine in the form of iodide of palladium, while the bromide of that metal will remain in solution. (*Ibid.*) Bromide of potassium consists of one eq. of bromine 78·4, and one of potassium 39·2 = 117·6.

Medical Properties. Bromide of potassium is alterative and resolvent, and is thought to be sedative to the nervous system and powerfully antaphrodisiac.* In 1828, Pourché used it with benefit, both internally and in the form of ointment, in the treatment of bronchocele and scrofula. Favourable results were obtained by the late Dr. T. Williams, of London, from its use as an internal remedy in enlarged spleen, and it has been given advantageously in goitre. According to Ricord, it produces effects in secondary syphilis similar to those of iodide of potassium, but acts more slowly. The same view is taken of its slow action in syphilis by Dr. John Egan. This surgeon, after experimenting with bromide of potassium for four years in the Westmoreland Lock Hospital, found its effects, in secondary and tertiary syphilis, slow and unsatisfactory, when compared with those of the iodide. While the latter generally increased the appetite and improved digestion, the bromide not unfrequently produced nausea and derangement of the digestive organs. M. Huette, from extensive trials of the remedy in the same stages of syphilis, found it inefficacious; exhibiting, in its effects, a marked contrast to iodide of potassium, which rapidly relieved the cases in which the bromide had failed. (*Ann. de Thérap.*, 1851, p. 216.) Given in large doses (from two to five drachms daily), it produces headache, followed by a peculiar intoxication, with torpor and drowsiness, slowness of the pulse, temporary dulness of sight and hearing, and weakness of the intellectual faculties. In one case, observed by M. Rames, the insensibility was so complete that the puncture of the skin with a suture needle was not felt, and the titillation of the conjunctiva and fauces with a feather produced neither winking nor desire to vomit. (*Journ. de Pharm.*, Dec. 1849.) Anæsthesia of the fauces, produced by the bromide, was

* For an account of experiments in reference to the physiological effects of bromide of potassium, for which we have not space here, the reader is referred to the Treatise by Dr. Wood on Therapeutics and Pharmacology (3d ed., ii. 398, A.D. 1868); and, since the publication of that work, for researches by Eulenburg and Guteman, to the *Annuaire de Thérapeutique* (1868, p. 191), and for similar experimental researches by Dr. J. H. Bill, U.S. Army, to the *Am. Journ. of Med. Sci.* (July, 1868, p. 17).—*Note to the thirteenth edition.*

subsequently observed by M. Huette, who also noticed in it the property of inducing more or less torpidity of the genital organs. Its powers as an antaphrodisiac have been confirmed by Dr. Thielmann, of St. Petersburg, M. Trousseau, of Paris, and subsequently by many others. Sir Charles Locock has used it advantageously in hysterical epilepsy, and other nervous affections connected with uterine disorder; and others have found it useful generally in cases of that disease not dependent upon incurable lesions. It has also proved advantageous in chorea. Dr. Garrod has found it powerfully sedative to the sexual function, and recommends it strongly in nymphomania, priapism, certain forms of menorrhagia, and even in ovarian tumours. (*Med. Times and Gaz.*, March, 1864, p. 276.) Dr. Bedford Brown, of Washington, D. C., has experienced great advantage from it, taken internally, in the resolution of enlarged testicles. (*Am. Journ. of Med. Sci.*, July, 1867, p. 97.) It is said to be efficacious in the painful erections occurring in gonorrhœa; and has been much used, with supposed benefit, in spermatorrhœa; but Dr. W. F. Munroe, of Boston, has failed with it in chordee, unless when associated with general nervous disorder. (*N. Y. Med. Journ.*, July, 1868, p. 327.) It is thought to have proved useful in hooping-cough. Dr. J. Jones, of London, has found it very effectual in certain infantile convulsions, given in the dose of two or three grains every four or six hours (*Ibid.*, p. 254); and a case of obstinate asthma, in the care of Dr. J. D. Palmer, of Monticello, Florida, was greatly benefited by its use. (*Bost. Med. and Surg. Journ.*, March 26, 1868, p. 127.) Dr. A. J. Stone, of Boston, speaks strongly of its efficacy in checking the nausea so apt to follow the use of ether as an anæsthetic (*Med. Record*, May 15, 1868, p. 137); and Dr. J. H. Packard, of Philadelphia, has employed it successfully in the nausea and vomiting of pregnancy, when owing to reflex irritation of the stomach. (*Am. Journ. of Med. Sci.*, July, 1868, p. 133.) By M. Ozanam, of Paris, it has been successfully used in fourteen cases of pseudomembranous affections, two of which were croup. It has been given with good effect by Mr. Spencer Wells, of London, in cancerous tumours, in the dose of from five to ten grains, with one, two, or three drachms of cod-liver oil, three times a day. (*Med. T. and Gaz.*, July, 1857, p. 31.) In reference to its anæsthetic action on the fauces, it has been usefully employed in examination of these parts, and in operations upon them. Besides the nervous affections mentioned above, it has been employed with more or less asserted advantage in neuralgia, palpitation of the heart, delirium, and other forms of mental disorder, and especially want of sleep. Perhaps in no morbid condition has it proved so efficacious, or been so much used, as in sleeplessness dependent on functional disorder.

Bromide of potassium may be given in the form of pill, or dissolved in water, in doses of from three to twenty grains three times a day. When used as an antaphrodisiac, the dose may be two or three grains every two hours. For procuring sleep, twenty grains of it may be given morning and evening, or three times a day, and continued for several days, when a permanent effect is required; and the same quantity, followed by half the dose every half hour or hour, at night when a temporary action only is wanted. The *ointment* may be made by mixing from a scruple to two drachms of the bromide with an ounce of lard. Of this from half a drachm to a drachm may be rubbed on a scrofulous tumour, or other part where its local action is desired, once in twenty-four hours. Sometimes bromine is aded to this ointment in the proportion of thirty minims to the ounce of lard. B.

POTASSII CYANIDUM. *U. S.* POTASSII CYANURETUM. *U. S.* 1850. *Cyanide of Potassium. Cyanuret of Potassium.*

"Take of Ferrocyanide of Potassium, dried, *eight troyounces;* Pure Carbonate of Potassa, dried, *three troyounces.* Mix the salts intimately, and throw the mixture into a deep iron crucible previously heated to redness. Maintain the temperature until effervescence ceases, and the fused mass concretes, of a pure white colour, upon a warm glass rod dipped into it. Then pour out the liquid carefully into a shallow dish to solidify, ceasing to pour before the salt

becomes contaminated with the precipitated iron. Break up the mass while yet warm, and keep the pieces in a well-stopped bottle." *U. S.*

The above process for obtaining this cyanide, which is that of F. & E. Rodgers, though generally known under the name of Liebig, was substituted, in the U. S. Pharmacopœia of 1850, for the process in which the ferrocyanide is ignited without addition. It furnishes a large product, but a considerable part of it is the impurity, cyanate of potassa. The reaction takes place between two eqs. of ferrocyanide of potassium and two of carbonate of potassa. The iron is set free, the carbonic acid evolved, and a compound of five eqs. of cyanide of potassium and one of cyanate of potassa is formed. The iron occupies the lower part of the fused liquid; and, if the latter be carefully poured out to solidify, the portion contaminated with the iron may be left behind. The reaction is explained by the following equation: $2(2KCy,FeCy)$ and $2(KO,CO_2) = 5KCy$ and KO,CyO and $2Fe$ and $2CO_2$. Dr. Wittstein gives the reaction differently, to explain the larger proportion of cyanate of potassa formed than the above equation calls for. He conceives that the product consists of seven eqs. of cyanide of potassium, and three of cyanate of potassa. MM. Fordos and Gélis, in an able paper contained in the *Journ. de Pharmacie* for Aug. 1857, have pointed out numerous causes which concur in rendering the salt, as obtained by the use of carbonate of potassa, impure. The commercial cyanide, which is obtained by this process, was found by these writers to be very impure, only containing from 36 to 55 per cent. of the pure salt. The cyanate of potassa may be readily detected by saturating the product with an acid, which will cause an effervescence of carbonic acid, and the generation of a salt of ammonia. According to Dr. Schwarz, it may be freed from cyanate and carbonate of potassa, by treating the impure cyanide with bisulphuret of carbon, which dissolves it, and may be recovered in great measure by distillation. (*Chem. News*, no. 190, p. 41.)

In the process in which the ferrocyanide of potassium is ignited alone (former U. S. process), the salt is first deprived of its water of crystallization by exposure to a moderate heat, and then calcined at a red heat for two hours, in order to decompose the cyanide of iron. The product of the calcination is a black, porous mass, consisting of cyanide of potassium, mixed with carburet of iron and charcoal. As the cyanide is very prone to absorb oxygen, especially when hot, whereby it is decomposed, atmospheric air is excluded from the retort while it is cooling, by luting its orifice. When the whole is cold, the black mass is reduced to coarse powder, and exhausted by cold distilled water, which dissolves the cyanide of potassium, and leaves the carburet of iron and charcoal behind. The filtered liquor, therefore, is an aqueous solution of cyanide of potassium, which is obtained in a solid state by a rapid evaporation to dryness. During the evaporation, a small portion of the cyanide is decomposed, attended with the evolution of ammonia, and the production of formiate of potassa. A portion of this salt, therefore, contaminates the cyanide, as obtained by this process; but the quantity is too small to interfere with its medicinal action. The decomposition here referred to takes place between one eq. of cyanide of potassium and four of water, and is represented by the following equation, in which the cyanogen is expressed by its full symbol NC_2, and formic acid by C_2HO_3: K,NC_2 and $4HO = NH_3$ and KO,C_2HO_3. This decomposition is avoided by exhausting the black mass with boiling alcohol of 60 per cent. (sp. gr. 0·896) instead of with water. The alcoholic solution, by evaporation to a pellicle, lets fall the salt upon cooling, as a crystalline precipitate, perfectly white and pure.

According to the process of the French Codex, which is that of Robiquet, this cyanide is obtained in the dry way, without the use of any solvent. The calcination is performed in a coated stoneware retort, half-filled with the ferrocyanide, to which a tube is attached for collecting the gaseous products. When these cease to be disengaged, the heat is gradually raised to a very high temperature, at which it is kept for a quarter of an hour; after which the tube is closed with luting, and the whole left undisturbed until quite cold. When the calcination is thus conducted, the retort, upon being broken, will be found to

contain a black matter, covered with a fused layer of pure cyanide of potassium, resembling white enamel. This is detached by means of a knife, and immediately transferred to a bottle, with an accurately fitting stopper. The black matter, under the name of *black cyanide of potassium*, is also kept for medicinal use; but the dose of this cannot be accurately fixed, on account of its containing, at different times, more or less impurity.

According to MM. Fordos and Gélis, the French Codex process should supersede the carbonate of potassa process; as it gives a product far purer, and in larger proportion to the materials employed, estimated by the pure product. The same process is preferred by Mr. Donovan, who has modified it by substituting, for the stoneware retort, an iron mercury bottle, which, when cold, must be cut in two by a chisel and hammer to get out the product. The same recommendation of iron in preference to stoneware vessels, is made by Fordos and Gélis, who found that the latter, at the high heat employed, were acted on.

The process of Wiggers consists in disengaging hydrocyanic acid from a mixture of ferrocyanide of potassium and sulphuric acid, and passing it into a cooled receiver, containing an alcoholic solution of hydrate of potassa. The contents of the receiver ultimately form a solid magma of the cyanide, which is drained, washed several times with strong alcohol, pressed between folds of bibulous paper, and dried as quickly as possible.

Cyanide of potassium may be formed by passing a current of strongly heated nitrogen over charcoal, impregnated with carbonate of potassa, and heated to white redness. (See *page* 715.)

Properties. Cyanide of potassium, as prepared by the U. S. formula, is in white, opaque, amorphous masses, having a sharp, somewhat alkaline and bitter-almond taste, and an alkaline reaction. If yellow it contains iron. It is deliquescent in moist air, readily soluble in water when reduced to powder, and sparingly soluble in strong alcohol. Its solution effervesces with acids. The salt and its solution, when exposed to the air, exhale the odour of hydrocyanic acid, and become weaker; but the change takes place slowly. Orfila found that the salt, after fourteen days' exposure, by which it was almost entirely liquefied, still possessed energetic poisonous properties. He thinks, therefore, that the bad effects of opening the containing bottle, in dispensing the medicine, have been exaggerated. Unfortunately, the salt varies in quality, independently of the effects of time and exposure. Dr. David Stewart, of Baltimore, examined six samples of this cyanide, on sale, and found them to vary considerably in purity. Besides water, the usual impurities are hydrate, carbonate, cyanate, and formiate of potassa. They sometimes amount to half the weight of the cyanide, consisting principally of the carbonate. From the extensive use at present made of cyanide of potassium in electro-metallurgy and photography, it is of importance to have a reliable test of its purity. Such a test has been discovered by MM. Fordos and Gélis, founded on the fact that two eqs. of iodine rapidly react with one of the cyanide, so as to form a colourless compound, consisting of one eq. of iodide of potassium, and one of iodide of cyanogen: KCy and 2I = KI and CyI. Accordingly, a tincture of iodine of known strength is gradually added to an aqueous solution of a given weight of the cyanide to be tested, until it assumes a permanent yellowish tinge; and the amount of iodine expended indicates the proportion of cyanide in the specimen. A necessary preliminary step, before using the tincture, is to add sufficient carbonic acid water to the solution of the cyanide, to convert any hydrate or carbonate of potassa present into bicarbonate, in which state neither has any action on the iodine. (*Chem. Gaz.*, Oct. 15, 1852, p. 387.) This test is applicable to other cyanogen compounds. (See *page* 964.) Mr. Thornton J. Herapath's test for commercial cyanide of potassium is a standard solution of ammonio-sulphate of copper, the blue colour of which is destroyed by a solution of the cyanide. The copper solution is added to one of the cyanide of known strength, until a faint blue coloration is produced; and the richness of the sample in pure cyanide is in proportion to the quantity of the copper solution required. (*Chemist*, April, 1856, and Feb. 1857.) Applying this test to five sam-

ples, Mr. Herapath found the proportion of pure cyanide to vary from 41 to 65 per cent. Cyanide of potassium yields with nitrate of silver a precipitate of cyanide of silver, wholly soluble in ammonia and boiling nitric acid. It consists of one eq. of cyanogen 26, and one of potassium 39·2 = 65·2.

Medical Properties. Cyanide of potassium is pre-eminently poisonous, acting precisely like hydrocyanic acid as a poison and as a medicine. (See *Acidum Hydrocyanicum Dilutum.*) Since the tenth edition of this work was published, three fatal cases of poisoning by this salt have occurred in the United States. The first case, reported by Dr. C. E. Ware, of Boston, was that of a woman who took, by mistake, a teaspoonful of a solution, containing about seven grains of the salt. The second and third cases occurred in Baltimore, and arose from the mistake of an apothecary in putting up cyanide of potassium for chlorate of potassa in a mixture. A dose of the mixture destroyed a child, and, likewise, the apothecary, who, to show his confidence in the correctness with which it had been compounded, swallowed a portion of it himself. Hydrocyanic acid has been detected in the blood of a person who had been fatally poisoned by the cyanide. (Venghauss, *Arch. der Pharm.*, clii. 138.) The grounds on which this cyanide was proposed as a substitute for hydrocyanic acid by Robiquet and Villermé, were its uniformity as a chemical product, and its less liability to undergo decomposition. The dose is the eighth of a grain, dissolved in half a fluidounce of distilled water, to which may be added half a fluidrachm of syrup of lemons, if the prescriber wish to set the hydrocyanic acid free. The spurious cyanide, formed by calcining dried muscular flesh with potash, consists principally of carbonate of potassa, and is but slightly poisonous. (*Orfila.*) A solution of cyanide of potassium, made with from one to four grains to the fluidounce of water, has been recommended in neuralgic and other local pains, applied by means of pieces of linen. Mr. Guthrie found that a solution of from three to six grains to the fluidounce of distilled water, answered admirably, applied by drops every other day, for removing the olive-coloured stains of the conjunctiva caused by nitrate of silver. B.

POTASSII IODIDUM. *U.S., Br. Iodide of Potassium.*

"Take of Potassa *six troyounces;* Iodine, in fine powder, *sixteen troyounces*, or *a sufficient quantity;* Charcoal, in fine powder, *two troyounces;* Distilled Water *a sufficient quantity.* To the Potassa, dissolved in three pints of Distilled Water, boiling hot, gradually add the Iodine, stirring after each addition until the solution becomes colourless, and continue the additions until the liquid remains slightly coloured from excess of Iodine. Evaporate the solution to dryness, stirring in the charcoal towards the close of the operation, so that it may be intimately mixed with the dried salt. Rub this to powder, and heat it to dull redness in an iron crucible, maintaining that temperature for fifteen minutes; then, after it has cooled, dissolve out the saline matter with Distilled Water, filter the solution, evaporate, and set it aside to crystallize. An additional quantity of crystals may be obtained from the mother-water by evaporating and crystallizing as before." *U. S.*

"Take of Solution of Potash *one gallon* [Imperial measure]; Iodine *twenty-nine ounces* [avoirdupois], or *a sufficiency;* Wood Charcoal, in fine powder, *three ounces* [avoird.]. Put the Solution of Potash into a glass or porcelain vessel, and add the Iodine in small quantities at a time with constant agitation, until the solution acquires a permanent brown tint. Evaporate the whole to dryness in a porcelain dish, pulverise the residue, and mix this intimately with the Charcoal. Throw the mixture, in small quantities at a time, into a red-hot iron crucible, and, when the whole has been brought to a state of fusion, remove the crucible from the fire and pour out its contents. When the fused mass has cooled, dissolve it in two pints [Imp. meas.] of boiling distilled water, filter through paper, wash the filter with a little boiling distilled water, unite the liquids, and evaporate the whole till a film forms on the surface. Set it aside to cool and crystallise. Drain the crystals, and dry them quickly with a gentle

heat. More crystals may be obtained by evaporating the mother-liquor and cooling. The salt should be kept in a stoppered bottle." *Br.*

In these processes, which are essentially the same, an aqueous solution of potassa is treated with iodine in slight excess. The result of thus saturating potassa with iodine is the formation of two salts, iodide of potassium and iodate of potassa. Six eqs. of iodine react with six of potassa, and there are formed five eqs. of iodide of potassium, and one of iodate of potassa ($6KO$ and $6I = 5KI$ and KO,IO_5). By evaporating the solution to dryness the mixed salts are obtained; and, if the dry mass be exposed to a red heat, the iodate will be converted into iodide of potassium, thus removing this impurity from the iodide. In the formula the mixed salts, towards the close of their evaporation to dryness, are directed to be mixed with powdered charcoal, according to the plan of Mr. Scanlan, which facilitates the deoxidation of the iodate. This being accomplished by a dull red heat, the iodide of potassium is dissolved out of the mass, and the solution set aside to crystallize.

In the late Ed. and Dub. processes the first step was to form iodide of iron in solution, precisely as is done in the formula for that compound; and the second to decompose it by carbonate of potassa, which gave rise to iodide of potassium in solution, and a precipitate of carbonate of protoxide of iron. The solution of iodide of potassium was separated by filtration and washing from the precipitated carbonate, and evaporated to dryness. The dry salt was then freed from iron and other impurities by solution in boiling water or alcohol, filtration, and crystallization. Messrs. T. and H. Smith, of Edinburgh, instead of washing the precipitate, prefer the plan of pressing it strongly in a cloth, in order to extract the remains of the solution. The mass left is broken up in a portion of distilled water equal to about two-thirds of the weight of the iodine employed, and pressed a second time. Proceeding thus, less water is used, and less evaporation is necessary. The solution obtained by them is evaporated to dryness, and the dry salt is carefully fused in an iron pot, in order to free it from colour. It is then dissolved, and the solution, by filtration, concentration, and cooling, furnishes a perfectly pure iodide nearly to the last.*

Properties, &c. Iodide of potassium, sometimes incorrectly called *hydriodate of potassa*, is in opaque, white or transparent crystals, permanent in a dry air, slightly deliquescent in a moist one, and having a sharp saline taste. It does not change the colour of litmus, and has little or no effect on turmeric. According to the Messrs. Smith, of Edinburgh, it is not at all deliquescent when perfectly pure. It generally crystallizes in cubes. It is soluble in about two-thirds of its weight of cold water, and in from six to eight parts of rectified spirit. If solution of iodide of potassium be mixed with solution of starch, and a minute quantity of solution of chlorine be added, a blue colour will be produced; the chlorine combining with the potassium and thus liberating the iodine which forms a blue compound with starch. Its solution is decomposed by the addition of a few drops of sulphuric acid, hydriodic acid being generated, which speedily undergoes decomposition, with evolution of iodine; and, if starch be

* For formulas by Prof. Mayer, of New York, for the preparation of the iodides and bromides, based on the reaction between iodine or bromine on the one hand, and iron and bicarbonate of potassa or the carbonate of soda, lithium, or lime, according to the particular iodide wanted, on the other, see the *Am. Journ. of Pharm.* (July, 1862, p. 292). Another process of Liebig, as detailed by Mr. Squire, will be found in the same journal for Sept. 1862 (p. 437). To 1 part of phosphorus covered with 40 parts of water, 20 parts of iodine are gradually added; the solution of phosphoric and hydriodic acids thus obtained is poured off, and milk of lime added in slight excess; the whole is placed upon a filter, and the precipitate, consisting of phosphate of lime, is pressed and washed: the filtrate, containing only iodide of calcium, is boiled down, with 12 parts of powdered sulphate of potassa, to about one-half; the whole, after standing six hours, is filtered, and the precipitate pressed as before; a little pure carbonate of potassa is added to the filtrate to remove every trace of lime; and the filtered solution, containing only iodide of potassium, yields that salt in crystals by concentration. By slight modifications of the process, the iodides of sodium, lithium, and various other metals may be obtained. (*Note to the twelfth edition.*)

added after the lapse of a few minutes, a blue colour is produced. The starch test will not give the characteristic blue colour immediately, if added simultaneously with the acid, unless the iodide of potassium contains iodate of potassa, which impurity causes an immediate liberation of iodine. The blue colour being produced by the starch and acid, if simultaneously added, is, therefore, a sign of impurity. A very delicate test of iodide of potassium, and other soluble iodides, is that of M Grange. It consists in pouring a little of the liquid to be examined into a test tube, adding a few drops of solution of starch, and passing through the mixture a few bubbles of fuming nitrous acid. The liquid immediately assumes a pale rose colour, inclining to violet, if containing 1-200,000th of its weight of the iodide, and a bright-blue colour, if 1-100,000th is present. (See *page* 484.) "When tartaric acid is freely added to a strong solution of the iodide, it occasions a white crystalline precipitate; and the supernatant liquid, if mixed with starch, becomes first purple, and finally blue. Bichloride of platinum colours its solution reddish-brown, without causing a precipitate; chloride of barium but slightly affects it; and sulphate of iron occasions no change." (*U. S.*) The non-action of the last test shows the absence of carbonate of potassa. The aqueous solution is capable of taking up a large quantity of iodine, forming a liquid of a deep-brown colour.

M. Payen has noticed a curious effect produced by iodide of potassium. In saturated solution, this salt causes in starch added to it an enlargement of its granules to twenty-five or thirty times their original volume, dissolving the interior substance of the granules, and enormously distending the exterior layer. The bromide of potassium produces the same effect; but the alkaline chlorides neither cause the enlargement referred to, nor a solution of the amylaceous substance; and, if the saturated solution of the iodide be diluted with three and a half volumes of water or more, it is inert in reference to starch in the cold. (*Journ. de Pharm.*, 4e sér., ii. 373.)

Exposed to a dull red heat iodide of potassium fuses, and on cooling concretes into a crystalline pearly mass, without loss of weight; but at a full red heat it is slowly volatilized without decomposition. The most usual impurities contained in this salt are the chlorides of potassium and sodium, bromide of potassium, and carbonate and iodate of potassa. According to M. Payen, the iodide of potassium of commerce generally contains carbonate of potassa and iodine in excess. (*Journ. de Pharm.*, 4e sér., ii. 373.) He states, however, that it may be easily purified by saturating the potassa with hydriodic acid, and then eliminating the excess of iodine by sulphuretted hydrogen, boiling, rest, and filtration. (*Ibid.*, p. 368.) The presence of a chloride may be determined by nitrate of silver. This test will throw down nothing from the pure salt but iodide of silver, which is scarcely soluble in ammonia; while chloride of silver is readily soluble in it. If then a solution of the iodide be precipitated by an excess of nitrate of silver, and agitated with ammonia, the latter will dissolve any chloride which may have been thrown down, and will yield it again as a white precipitate on being saturated with nitric acid. If, on the other hand, the iodide of potassium be pure, the ammonia will take up only a minute quantity of iodide of silver, and the addition of nitric acid will scarcely disturb the transparency of the solution. The iodide of silver precipitated from 10 grains of iodide of potassium weighs, when washed and dried, 14·1 grains. When acetate of lead is added to a solution of iodide of potassium, a yellow precipitate of iodide of lead is thrown down, soluble in boiling water. The low price of bromide of potassium, compared with that of the iodide, has caused the former to be used to adulterate the latter. When bromide of potassium is sold for the iodide, the fraud may be detected by the fact that the addition of sulphuric acid produces copious reddish fumes, instead of the purple ones, arising from the iodide. In order to detect bromine, M. Personne first precipitates from an aqueous solution of the suspected iodide, the whole of the iodine as protiodide of copper, by successively adding, in excess, a solution of sulphate of copper, and aqueous sulphurous acid; and then treats the filtered liquid with ether and

chlorine water, the whole being shaken together and left at rest. If bromine be present, the ether which rises to the surface will be tinged of a reddish-yellow colour. Fresenius's test of chloride of gold is, according to Dr. J. H. Bill, of the U. S. Army, very delicate. The iodine having been separated by palladium, and the excess of palladium by sulphuretted hydrogen, the solution supposed to contain bromine, if treated first with a drop of muriatic acid, and then with a drop of solution of chloride of gold, will, if bromine be present, exhibit a decided yellowness, which will appear more obviously if the solution be compared with pure water or a weak solution of a chloride. (See *Am. Journ. of Pharm.*, May, 1868, p. 272.) Carbonate of potassa may be discovered by lime-water, which causes a milkiness (carbonate of lime), and by tincture of iodine, the colour of which is destroyed. The Br. Pharmacopœia admits a slight degree of this impurity, directing that saccharated solution of lime should only faintly precipitate the solution. The iodate may be detected by adding a solution of tartaric acid to a solution of the suspected iodide. Bitartrate of potassa will be precipitated, and, if the iodide be pure, a yellow colour is *soon* developed by the action of the air on the liberated hydriodic acid; but, if any iodate be present, the test will give rise to both iodic and hydriodic acids, which, by their mutual action, will *instantly* develop iodine.

Mr. William Copney has pointed out an excellent test for detecting carbonate and iodate of potassa, in the use of protiodide of iron, in the form of syrup of iodide of iron, recently prepared. (See *Syrupus Ferri Iodidi.*) A drop of the syrup is added to a solution of the suspected iodide of potassium. A bluish precipitate indicates the carbonate; a red one, the iodate; and a blue precipitate, followed by a red one, both impurities. Carbonate of potassa is generally present in the proportion of from 1 to 10 per cent. Dr. Christison has detected 74½ per cent., and Dr. Pereira as high as 77 per cent. An adulteration by the carbonate under 10 per cent. does not alter the crystalline appearance of the iodide, but gives it an increased tendency to deliquesce. When it is greater it renders the salt granular and highly deliquescent. As iodide of potassium is soluble in rectified spirit, anything left undissolved by that menstruum is impurity. The amount of impurity in this salt, without ascertaining its nature, may be determined by the method of Marozeau, which consists in adding a solution of corrosive sublimate to one of the iodide to be examined, the salts being taken in the proportion of four eqs. of the iodide to one of the bichloride. If the iodide be pure, its excess will be just competent to redissolve all the red iodide of mercury formed by the addition of the corrosive sublimate solution. If impure, a reddish colour from undissolved red iodide will appear before the whole of the latter solution is added. Accordingly, if a solution of one eq. of corrosive sublimate be gradually added to a solution of four eqs. of the iodide, until the reddish colour ceases to disappear upon stirring, the proportion expended will represent the pure iodide, and that unexpended, the impurity in the specimen examined. (See a paper of Mr. J. M. Maisch, in the *Am. Journ. of Pharm.*, xxvi. 293.) Iodide of potassium consists of one eq. of iodine 126·3, and one of potassium 39·2 = 165·5. It contains no water of crystallization.

According to M. Payen, a saturated solution of iodide of potassium, which will evince signs of decomposition by becoming orange-yellow, in the presence of atmospheric air, on the addition of small quantities of acetic, nitric, oxalic, and probably many other acids, remains unaffected by these additions if atmospheric air be excluded. The air oxidizes a portion of the potassium, which then unites with the acid, and the iodine liberated gives colour to the solution. (*Journ. de Pharm.*, 4e sér., iii. 200.)

Prof. Procter has given a paper on the incompatibles of iodide of potassium in relation to the mercurial preparations. He finds it incompatible with calomel, the black and red oxides of mercury, turpeth mineral, white precipitate, blue mass, and metallic mercury. These experiments serve to confirm the observation of M. Melsens, that iodide of potassium, given in connection with the insoluble preparations of mercury, renders them soluble and much more active.

(See *Am. Journ. of Pharm.*, xxvi. 222.) With nitrous ether iodide of potassium reacts, yielding, among other products, hydriodic ether and a little ordinary ether. (Juncadella, *Comptes Rendus*, Fév. 1859, p 345.) At ordinary temperatures iodide of potassium is slowly decomposed, with evolution of iodine, by nitrate of ammonia and boracic acid; and at high temperatures, in a glass test tube, with escape of violet vapours, not only by the two substances just named, but also by sulphate, oxalate, carbonate, and muriate of ammonia, sulphate, phosphate, nitrate, and borate of soda, sulphates of potassa and magnesia, nitrate of lime, chlorides of sodium, potassium, and calcium, and silicic acid. (Ubaldini, *Journ. de Pharm.*, Oct. 1859, p. 292.) To M. Melsens we are indebted for another important fact in relation to the operation of iodide of potassium. When this salt and chlorate of potassa are mixed in solution, no change takes place at ordinary temperatures; but if a certain amount of a mineral acid be added to the solution of the mixed salts, a reaction occurs, attended with the escape of iodine; and evidences are presented of the existence of iodic acid in the solution. Now M. Melsens has ascertained by experiments on dogs that neither of these salts, if given separately and at different times, produces any evil effect; while, if given together, so as to be in the system at the same time, they act as a poison, and may cause death in a few days. Seven grammes (108 grains) of a mixture of iodide of potassium and chlorate of potassa, in equivalent proportions, given daily to a dog of medium size, uniformly proved fatal in less than a month, and often as early as the fifth day. M. Melsens ascribed the result to the production of iodate of potassa, which he has shown to be a poisonous salt. (*Am. Journ. of Pharm.*, Nov. 1866, p. 521; from *Bullet. de la Soc. Chem. de Paris.*)

Medical Properties, &c. The general therapeutic properties of the preparations of iodine, of which iodide of potassium is the most important, have been given under the head of iodine. By most practitioners the preparation under notice is preferred for producing the constitutional effects of iodine. It certainly produces very marked effects on the secretions, which it uniformly increases, and into which it readily passes. It has a tendency to irritate the mucous membrane of the air-passages, as shown by its sometimes occasioning an affection like cold in the head. When long continued in large doses, it occasionally produces a tender, enlarged, lobulated, and fissured tongue, constituting a true chronic glossitis. Mr. Langston Parker, of England, has reported several cases of this kind, in which the iodide had been taken for years. Its obvious effects on the system are very variable, arising probably either from peculiarities of constitution, or from the unequal quality of the medicine itself. Thus it produces nausea, pain in the stomach, and diarrhœa, in moderate doses, in some cases; and is borne in large doses without inconvenience in others. It generally increases the appetite and flesh. The general character of its action is to remove abnormal tissue, eliminating the material for the most part by the channel of the kidneys. There are few diseases in which it has not been tried. Its use in scrofulous affections, combined with iodine, has been explained under the head of iodine. It has been recommended by M. Oke in chorea, after the preparations of iron have failed; by M. Gendrin, Dr. Clendenning, and Mr. Spencer Wells in gout; by M. Arrigan in albuminuria; by Mr. Sankey in ague, given in large doses; and by MM. Demarquay and Gustin in stomatitis. The latter writers think it more efficacious in this disease than chlorate of potassa.

Dr. Williams, of London, considers it applicable to the treatment of various forms of secondary syphilis. He used it with success, in a majority of cases, in removing hard periosteal nodes, and found it beneficial in the treatment of tubercular forms of venereal eruptions. It is also considered as one of the best alterative remedies in mercurio-syphilitic sorethroat. Ricord bears testimony to its valuable powers in the treatment of secondary syphilis. Dr. Hanfield Jones found it particularly efficacious in that form of rheumatism characterized by wandering pains in the bones. According to the clinical observations of Dr. W. R. Basham, iodide of potassium is well suited to the treatment of chronic periosteal

rheumatism in subjects who have previously taken mercury to salivation; while it is not applicable to the disease when occurring in patients who have not undergone a mercurial course, but have suffered from syphilis, which has been neglected, or treated only locally. In the latter cases he conceives that corrosive sublimate and sarsaparilla are the proper remedies. It is probably useful in the former cases on the principle of eliminating mercury from the system, agreeably to the views of M. Melsens given below. In 1843 MM. Guillot and Melsens gave iodide of potassium with advantage, in doses of from a drachm to a drachm and a half daily, in mercurial tremors and lead poisoning. In a memoir published in 1849, M. Melsens gives a full account of his experiments with it as a remedy for the affections caused by mercury and lead. He effected a number of cures of mercurial tremors and lead palsy; and, during the progress of the cure, these metals were found in the urine. The manner in which the remedy acts, according to M. Melsens, is by rendering the poisonous metal, which has become fixed in the tissues, soluble, first converting it into an iodide, and then dissolving the iodide formed. This view is supported by the fact that all the compounds of mercury and lead are soluble in iodide of potassium.*

The views and results of M. Melsens have been confirmed by therapeutic trials in lead poisoning by M. Malherbe, of Nantes, and by Drs. Parke and Sieveking, of London. An important fact observed by M Melsens was that iodide of potassium, given at the same time with certain compounds of mercury, rendered them more active; and, when given after them, developed an activity not previously manifested, and sometimes to such an extent as to occasion serious accidents. This fact he explained by referring it to the power of the iodide to render the mercurial compounds soluble, in which state only are they capable of being eliminated with the urine. During the use of iodide of potassium, ptyalism sometimes occurs. This has been usually considered a primary effect of the remedy; but the light shed on the subject by M. Melsens leads to the belief, that it may be a secondary effect, resulting from the liberation from the tissues of mercury previously taken, which is thereby enabled, by becoming soluble, to produce its constitutional effects. Dr. Budd relates several cases, in which mercurial ptyalism came on, during the use of iodide of potassium, in persons who had not taken mercury for weeks or months before. It is probable that, in these cases, the mercury had been long lying fixed in the system, and was rendered soluble and active by the iodide.

Dr. G. W. Balfour, of Edinburgh, has published several cases of aneurism of the aorta, in which iodide of potassium was given in the dose of thirty grains twice or thrice daily, with apparently great advantage; the symptoms of the disease having not only been greatly relieved, but in some instances having entirely disappeared. (*Edin. Med. Journ.*, July, 1868, p. 33.)

The late Dr. Isaac Parrish, of this city, employed iodide of potassium successfully in strumous inflammation of the eye, given in the compound syrup of sarsaparilla. It appeared promptly to relieve the severe neuralgic, circumorbital pain. Dr. Griscom, also of this city, cured a case of supposed membranous croup in a child by the use of this remedy, after leeches, sinapisms, warm baths, and emetics had failed. (*Trans. of the Coll. of Phys. of Philad.*, N. S., ii. 164.) Dr. De Renzy, of Carnew, Ireland, found it efficacious in hæmoptysis. Dr. G. L. Upshur, of Virginia, recommends its use in the suppurative stage of pneumonia.

Iodide of potassium has been used internally by Dr. A. Beaufort, with much supposed advantage in reference to its local effects. Being largely secreted with the tears, and to a certain extent with the uterine fluids, he gives it with a view to its effects on the passages with which it thus comes in contact. In this way he explains the very good effects he has experienced from it in chronic inflammation of the lachrymal passages, and in chronic metritis with copious leucorrhœa. (*B. & F. Med.-chir. Rev.*, Oct. 1868, p. 517; from *Bullet. Gén. de Thérap.*, Jan. 3, 1868.)

* See the Memoir of M. Melsens, translated by Dr. Budd, of Bristol, England, in the *Brit. and For. Medico-chir. Review*, Am. ed., for Jan. 1853, p. 157; also a paper by Dr. J. W. Corson, in the *N. Y. Journ. of Med.* for Sept. 1853.
